THE TRIAL, EXECUTION, AUTOPSY, AND MENTAL STATUS OF LEON F. CZOLGOSZ, ALIAS FRED NIEMAN, THE ASSASSIN OF PRESIDENT McKINLEY.

By CARLOS F. MacDONALD A.M. M.D.,
NEW YORK.
PROFESSOR OF MENTAL DISEASES AND MEDICAL JURISPRUDENCE IN THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; EX-PRESIDENT OF THE NEW YORK STATE COMMISSION IN LUNACY.

WITH A REPORT OF THE POST-MORTEM EXAMINATION.

By EDWARD ANTHONY SPITZKA,
COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK CITY.

THE terrible shock which the assassination of President McKinley by Leon Czolgosz at Buffalo, New York, on September 6, 1901, imparted to the entire civilized world, and which naturally engendered in the public mind a mingled feeling of horror, vindictiveness, and revenge—a feeling that was exceeded only by the profound sense of sorrow and depression which took possession of the people when a few days later it was realized that despite the highest efforts of surgical and medical skill a fatal result to the distinguished victim was inevitable—naturally suggested, both to the lay and medicolegal mind, the need of inquiry as to the mental status and responsibility of the perpetrator of so repulsive and atrocious an act. Moreover, there are many persons who are disposed to hold that the enormity of such a crime is in itself sufficient evidence to warrant the opinion of the existence of insanity, merely because it seems to them inconsistent with the principles of ordinary rational conduct, even though aside from the act itself there be nothing in the entire life and conduct of the individual that is suggestive of mental disease. On the other hand, there are many who, in view of the magnitude of the crime, would oppose the granting of exemption from the ordinary consequences of capital offenses, even though the offender were a raving maniac. Suffice it to say that the position taken by such persons, in either case, is untenable, and would be an untrustworthy test of responsibility as regards the ends of justice, whether viewed from a legal or a medical standpoint.

It need scarcely be said that the question as to whether or not a certain act is the offspring of mental disease cannot always with safety be determined by the act itself, but must be determined by all the attendant circumstances leading up to and surrounding the act.

"An act of violence," says Ray, "must not be attributed to insanity merely because to a person of high culture and correct morals it seems inexplicable on the ordinary principles of human conduct."

According to the Code of Criminal Procedure of the State of New York, Section 21, the legal test of mental unsoundness, as applied to criminal cases, is based on the assumption that insanity is a question of law, to be determined by the court, and that the question of responsibility in mental disease hinges upon a knowledge of right and wrong as to the particular act at the time it was committed; whereas medical science holds that insanity, in its relation to crime, is always a question of fact to be determined like any other fact in evidence, aided, of course, in such case, by the interpretation of expert opinion evidence, and that whenever its presence can be so determined, the accused should be absolved from responsibility, irrespective of the form or degree of his mental disease, or the nature of the act committed. "All that medical science has to do in any such case," says Dr. John P. Gray, "is to say whether the deed springs from disease or not. If it does not, the man is responsible, however ghastly, seemingly purposeless, or vindictive the act may be." In other words, medical science holds that the whole question of responsibility should rest upon the presence or absence of mental disease, and not upon a knowledge of right and wrong, as regards the nature and consequences of the act in question, and that that which in fact is a condition of mental disease cannot in law be a condition of mental health.

The question to be determined, then, in the case of Czolgosz, from the legal standpoint, as embodied in the Code of Criminal Procedure of the State of New York, was: When he shot the President did he know the nature and quality of the act he was doing, and that the act was wrong? If this question could be determined in the affirmative, then he was responsible under the law and punishable for the offense which he committed, even though he was medically insane, so to speak.

On the other hand, the question to be determined from the standpoint of medical science was: Was Czolgosz at the time he committed the act a victim of mental disease or mental unsoundness? If so, according to the dictum of medical science, he was not responsible and hence not punishable for the act he committed. These are the sole questions upon which the guilt or innocence of the accused must rest, whether in the eyes of the law or in the judgment of medical science, and it follows logically that if he were guilty of crime owing to the absence of mental disease, he was equally guilty within the intent and meaning of the statute. Such being the case, the subject of the responsibility of the accused resolves itself into a question of health or disease—sanity or insanity. Hence the application of the legal test may be dismissed from further consideration here and we may proceed to consider the question of his responsibility from a medical point of view.

The Trial.—The trial of Czolgosz, which took place in the city of Buffalo, N. Y., on September 23-24, 1901, Hon. Truman C. White, presiding justice, was neither attended by delay "nor harassed by the trivial technicalities of the law." The "machinery of justice" moved so smoothly and so rapidly that the jury was procured, the case tried, and a verdict of guilty rendered within a period of two court days with sessions from 10 to 12 o'clock in the forenoons and 2 to 4 o'clock in the afternoons, the time actually occupied being eight and a half hours in all. The proceedings were marked by no melodramatic or sen-

sensational episodes or unseemly wrangling among counsel, while the fact that, under the extraordinary circumstances, the trial was not anticipated or interrupted by any riotous demonstration against the prisoner—any attempt at mob or lynch law—when he appeared in public, affords striking proof of the respect for law and order which prevails in the community where the trial was held. Czolgosz was brought into court closely guarded by a double cordon of police and handcuffed to an officer on either side. He was neatly dressed and cleanly in appearance, his face clean-shaven and hair neatly combed.

The preparation and trial of the case on the part of the people by the Hon. Thomas Penny, District Attorney, and his assistant, Mr. Haller, was well-nigh faultless. Shortly after his arrest, the District Attorney procured from Czolgosz a statement several pages in length which was taken down in longhand, in narrative form, each page of which he signed after himself making corrections and revisions as to matters which he claimed the reporter had misapprehended. This statement gave in detail facts concerning his premeditations and preparations for the crime, also his movements for some time prior and up to the time of the shooting. The District Attorney also, within a few hours after the crime was committed, proceeded to put the prisoner under the observation of local experts in mental disease, namely, Drs. Joseph Fowler, Police Surgeon Floyd S. Crego, and James W. Putnam. These physicians had free access to him, down to and during the trial—covering a period of nearly three weeks, during which they examined him repeatedly and made a careful study of his case with reference to his mental condition. The District Attorney also permitted the experts on either side to confer together freely, and allowed those for the defense to have free access to all facts and information relative to the case in his possession—a proceeding which in effect was equivalent to the appointment of a commission of five experts, three for the prosecution and two for the defense, to determine the prisoner's mental condition. This course on the part of the District Attorney marks a new departure in the methods of getting expert evidence in criminal trials where the question of mental responsibility is involved, which is to be highly commended as a practical measure, tending to eliminate much superfluous testimony and at the same time to minimize the danger of contradictory expert opinions.

In view of the great importance of the case, it is regrettable that no experts were called to testify on the trial as to the prisoner's mental condition in order that it might appear on the record of the trial that his mental state was inquired into and determined by competent authority. Had the experts on either side been given the opportunity of thus stating officially their unanimous conclusion, together with the grounds on which it was based and the methods by which it was reached, it would have left in the public mind no room for reasonable doubt as to its absolute correctness, and that it had been arrived at only by the rules of professional conduct governing the examination of such cases.

The attorneys assigned by the court to the defendant, at the request of the Bar Association of Erie County, were ex-judges Loran L. Lewis and Robert C. Titus, both prominent lawyers and highly respected citizens of Buffalo. For obvious reasons these gentlemen were reluctant to undertake what they regarded as a most distasteful task, and consented to do so only from a high sense of duty to the public, at the urgent solicitation of the President—Hon. Adelbert Moot—and other prominent members of the Bar Association, on Saturday, September 21, preceding the trial, which began on Monday, the 23d.

Respecting the defence, it appears that substantially no preparation was made beyond a fruitless effort of counsel to confer with the prisoner and the examinations made of him at their request by Dr. Hurd and the writer, with reference to his mental condition, and a verbal statement by them to counsel of their conclusion that he was not insane. It also appears that no plea was entered by the attorneys for the defense; but Czolgosz, speaking for the first time in court, entered a plea of guilty to the indictment, which plea the court promptly rejected and directed that one of not guilty be entered on the record for the defendant.

Each juror on qualifying said, in answer to the usual question, that he had formed an opinion as to the guilt of the prisoner, but that his opinion could be removed by reasonable evidence tending to show that the defendant was innocent. And yet, to one accustomed to being in court and observing jurors when qualifying, it was difficult to avoid the impression that each of the jurors in this case held a mental reservation to convict the prisoner. Had Czolgosz been on trial for the murder of a common citizen, instead of the President, it is safe to say that not one of the jury as completed would have been accepted by the defense; and instead of getting a jury in approximately one hour and a half, that feature of the trial alone would probably have occupied several days.

Having in view the nature and importance of the case, the fact that no testimony was offered on the defendant's behalf and that practically no defense was made, beyond a perfunctory examination of jurors and a mild cross-examination of some of the people's witnesses, which was limited to efforts to elicit information respecting the President's condition during his illness and of his body after death, and a summing up by one of the counsel—Judge Lewis—which consisted mainly of an apology for appearing as counsel for the defendant and a touching eulogy of his distinguished victim, renders the case, in this respect, a unique one in the annals of criminal jurisprudence.

The jury retired for deliberation about 4 P.M., and returned in less than half an hour with a verdict of guilty of murder in the first degree. Czolgosz heard the verdict of the jury standing and without appreciable display of emotion. Several of the jurors were reported to have said, after the trial, that the jury was in favor of conviction unanimously from the first, and could have rendered a verdict without leaving their seats, but deemed it best to make a pretense of deliberation "for appearance' sake." Czolgosz was remanded to jail for two days, and on Thursday, September 26, was sentenced to be executed by electricity at Auburn Prison, in the week beginning October 28, 1901.

When Czolgosz returned to his cell, after his conviction, he ate a hearty supper, and soon thereafter went to bed and slept continuously until midnight, when the guard was changed, when he awoke for a few minutes, and then slept again until 6 A.M., when he arose and took a short walk in the cell corridor, after which he made a careful toilet, and at 7.30 partook of a hearty breakfast. He talked freely, as usual, on ordinary topics, but maintained his usual silence respecting his crime, and would not talk of the trial or the verdict. On Thursday, September 26th, he was removed from the Buffalo jail to the State Prison at Auburn, N. Y., where he was confined in a "death cell" until his execution took place.

The Execution.—Czolgosz was executed by electricity on the morning of October 29, 1901. The official witnesses, consisting of the Superintendent of State Prisons and other prominent New York State officials, several physicians, three representatives of the respective press associations, Mr. Spitzka, and others, and the official physicians—Dr. John Gerin, prison physician, and myself—having been assembled in the execution room and having received the usual admonition from the Warden as to the maintenance of order during the execution, the prisoner was conducted to the room a few minutes after 7 A.M. Every precaution was taken by the Warden, who had immediate charge of the execution, to minimize the opportunity for notoriety or sensationalism on the part of the prisoner, as well as to insure that his taking off should be effected in an orderly and dignified manner.

As Czolgosz entered the room he appeared calm and self-possessed, his head was erect and his face bore an expression of defiant determination. The guards, one on either side, quietly and quickly guided him to the fatal chair, the binding straps were rapidly adjusted to his arms, legs, and body, and the head and leg electrodes were quickly placed *in situ*, and connected with the wire which was to transmit the lethal current through his body. These preliminaries occupied about one minute. Czolgosz offered no resistance whatever, but during the preparations addressed himself to the witnesses in a clear, disdinct voice in the following significant language: "I killed the President because he was the enemy of the good people—the good working people. I am not sorry for my crime. I am sorry I could not see my father." At this moment, everything being in readiness, the Warden signalled the official electrician in charge of the switch, who immediately turned the lever which closed the circuit and shot the deadly current through the criminal's body, which was instantly thrown into a state of tonic spasm involving, apparently, every fiber of the entire muscular system. At the same time, consciousness, sensation, and motion were apparently absolutely abolished.

Two electrical contacts were made, occupying in all one minute and five seconds. In the first contact, the electro-motive pressure was maintained at 1,800 volts for seven seconds, then reduced to 300 volts for twenty-three seconds, increased to 1,800 volts for four seconds, and again reduced to 300 volts for twenty-six seconds—one minute in all—when the contact was broken. The second contact, which was made at the instance of the writer as a precautionary measure, but which was probably unnecessary, was maintained at 1,800 volts for five seconds. That conscious life was absolutely destroyed the instant the first contact was made, was conceded by all of the medical witnesses present; also that organic life was abolished within a few seconds thereafter.

Czolgosz was pronounced dead by the attending physicians and several of the other physicians present, after personal examination, in four minutes from the time he entered the room. One minute of this period, as already stated, was occupied in the preliminary preparations; one minute and five seconds in the electrical contacts, and the remainder of the time in examinations by the physicians to determine the fact of death. The physicians present at the execution and at the autopsy were Drs. H. O. Ely of Binghamton, N. Y.; W. A. Howe of Phelps, N. Y.; G. R. Trowbridge of Buffalo, N. Y.; W. D. Wolff of Rochester, N. Y., and C. R. Huntley of Buffalo.

The Autopsy.—The autopsy was made by Mr. Edward A. Spitzka, under the direction of the official physicians—Dr. Gerin and myself. The examination occupied about four and a half hours, and embraced a most careful, gross examination of all the viscera, attention being especially directed to the brain and its meninges. The accompanying masterly description of the post-mortem findings and especially of the condition and anatomical structure of the brain by Mr. Spitzka leaves nothing to be said here upon this point beyond the fact that the autopsy revealed no evidence whatever of disease or deformity of any of the bodily organs including the brain, which was normal in size, shape, weight, and appearance, and was well developed in all respects—a conclusion which was concurred in by all of the physicians present, several of whom had witnessed the execution.

In deference to the expressed wish of the relatives of Czolgosz, and for reasons of a sentimental nature on the part of the State authorities, the prison warden declined positively to allow any portion of the body to be removed from the prison. Consequently and regrettably, it was impossible for the examiners to retain honorable possession of any portion of the brain for microscopic examination and study. Accurate measurements, however, of the head and its appendages, of the face and of the exterior and interior of the skull, together with detail anatomical drawings and descriptions of the brain were made; also plaster molds of the head from which a cast was subsequently made, and photographs of the same—full face and profile—taken. These measurements, together with plates of the drawings and photographs, are presented in Mr. Spitzka's report of the autopsy.

In view of its great importance, both to medical science and to medical jurisprudence, the writer regards it as fortunate that the State was able to secure the services of so able a brain anatomist and skilled operator and draughtsman as Mr. Spitzka, to make the post-mortem examination.

The Mental Status.—On Thursday, September 19, 1901, I received a telegram requesting me to meet Mr. Adelbert Moot, President of the Erie County Bar Association, in Buffalo, New York, on the following morning. On my arrival in Buffalo the next day, Mr. Moot informed me that he had sent for me for the purpose of requesting me to inquire into the mental condition of Leon F. Czolgosz, confined in the Buffalo jail under indictment for the murder of President McKinley, and whose trial was to begin on the following Monday. Mr. Moot further stated in substance that three local experts had already examined the prisoner for the district attorney, but in view of the enormity of the offense and the fact that there obviously could be no legitimate defense other than insanity, it was deemed important, in the interests of justice, that his mental condition should be investigated by other experts acting in behalf of the defense, or a least independently of the prosecution, to the end that the prisoner should be accorded every legal right, there being no desire to convict him if he were not mentally responsible, and that I had been selected for the responsible duty. With a deep sense of the responsibility involved, I consented to act, provided it should be distinctly understood that I was not there as a partisan expert in behalf of either side, but simply in a professional capacity to aid in determining the real mental state of the prisoner; and providing further, that my selection would be acceptable to the eminent counsel whom the Bar Association had selected for the defense, should they decide to accept that duty, a matter which was then undecided. On the following morning (Saturday), Mr. Moot informed me that the gentlemen referred to had consented to act and invited me to meet them in conference, which I did, and which resulted in their requesting me to proceed at once to examine into the prisoner's mental condition, and to report my conclusion to them as soon as I had reached one. They also assented readily to my proposal to invite Dr. Arthur W. Hurd to become associated with me professionally in the case, Dr. Hurd being the Superintendent of the Buffalo State Hospital for the Insane, and a competent alienist of large experience in mental disease. It was also agreed that we should be allowed to confer freely with the District Attorney and with the experts for the people while completing our personal examination of the prisoner. Being unable to establish communication with Dr. Hurd before evening of that day, and in view of the short time intervening before the trial, I decided to make a preliminary examination of Czolgosz alone, and did so that afternoon in the District Attorney's office, first disclosing to him my identity and the object of my interview and informing him of his entire freedom to decline to answer any question I might ask him.

I examined him again the following day—Sunday—at the jail, jointly with Dr. Hurd and in the presence of one of his guards, who was questioned at length regarding his observations of him at jail, as to his habits of eating, sleeping, talking, reading, etc. We subsequently interviewed the District Attorney and the Superintendent of Police, General Bull, who gave us all the facts and information in their possession respecting the case. The statement which Czolgosz made to the District Attorney shortly after his arrest throws much light on his mental condition on the day of the crime, but that official deemed it his duty to refuse to allow me to publish it. We also conferred at length with the people's experts, Drs. Fowler, Crego, and Putnam, who stated to us separately and in detail their observations and examinations of him. We also observed him carefully in the court room throughout the trial.

After our examination of Czolgosz on Sunday, we reached the conclusion, independently of each other, that he was sane, and we so informed his counsel on Monday morning before the trial began.

It should be said that owing to the limited time—two days—at our disposal prior to the trial, and the fact that his family relatives resided in a distant State and were not accessible for interrogation, we were unable to obtain a history of his heredity beyond what he himself gave us.

Czolgosz, as he appeared at the time of my examination of him at Buffalo, may be described as a well-nourished, rather good-looking, mild-mannered young man, with a pleasant facial expression, features, regular, face smooth-shaven and symmetrical; mouth and ears, well formed and symmetrical, teeth, none missing, but in poor condition from neglect; tongue, clean; palate, fauces, and uvula, normal in appearance; eyes blue and normal in expression; pupils, equal in size, and normally responsive to light and accommodation; hair, light brown and slightly curly; stature, medium—five feet seven and a half inches; and weight, estimated, about 140 pounds. The extremities were in all respects normal. The external genitals were normal, excepting two small flat, unindurated cicatrices on the mucous surface of the prepuce, probably the result of previous chancroids, although he denied having had venereal disease other than gonorrhœa. There were no signs of specific nodes or periosteal tenderness over the usual sites of these lesions, nor was there any evidence upon the head or body of traumatism, excepting a slight deviation of the nose due to a blow which he received at the time of the assassination, and a superficial, perpendicular cicatrix on the left face which he said was the result of a slight injury he received when working in a barbed-wire factory. There were no tremors or twitchings of the facial muscles, tongue, or hands. The pulse, temperature, and skin were normal, as also were the special senses, knee reflexes, co-ordinating power, and the sensory and motor functions. Finally, a careful inspection of the entire visible body failed to reveal the presence of any of the so-called stigmata of degeneration. The almost perfect symmetrical development—especially of the head and face—is a noteworthy feature in Czolgosz' case, although had deviations been found the fact would have had little weight as tending to show mental disease or degeneracy, as marked asymmetries, both cranial and facial, are frequently observed in persons who are quite sane and above the average in mental capacity.

In answer to questions he stated, in substance, that he was born in Detroit, Michigan, of Polish parentage; that he was twenty-eight years of age, unmarried, and a laborer by occupation; that he was a Romanist originally, but had abandoned that faith several years ago because he no longer believed in it; that he attended the common schools as a boy and had learned to read and write; that he had used beer and tobacco, but not to excess; that he had done various kinds of unskilled labor, such as farming, factory hand work, etc.; that his mother was dead, and his father, one brother, and a married sister were living; that so far as he knew there was no insanity in his family, and that he had not suffered any serious illness or injury during his lifetime; that he had never been subject to fits, spasms, or vertigo; that he usually ate and slept well, and that his bowels were always regular. He admitted having had sexual intercourse with women, but denied masturbation, or other unnatural practices.

Careful inquiry failed to elicit any evidence of delusion, hallucination, or illusion. When questioned as to the existence of enemies, persecutions, or conspiracies against him, he replied in the negative. He evinced no appearance of morbid mental depression, morbid mental exaltation, or of mental weakness or loss of mind; nor did he display any indication of morbid suspicion, vanity, or conceit, or claim that he was "inspired" or had "a mission to perform," or that he was subject to any uncontrollable impulse. In fact, as regards the existence of evidences of mental disease or defect, the result of the examinations was entirely negative. On the contrary, everything in his history, as shown by his conduct and declarations, points to the existence in him of the social disease, anarchy, of which he was a victim.

My last examination of Czolgosz was made jointly with Dr. Gerin, physician of Auburn Prison, the evening before his execution. This examination revealed nothing either in his mental or physical condition which tended to alter the opinion I gave to his counsel at the time of his trial, namely, that he was sane—an opinion which was concurred in by all of the official experts on either side, namely, Drs. Fowler, Crego, and Putnam, for the people, and Dr. Hurd and myself for the defense, also by Dr. Gerin, the only other physician who examined him. Furthermore, the prisoner's manner, appearance, and declarations in the execution room, together with the post-mortem findings, corroborated most conclusively the original opinion as to sanity, while his dying declarations that he killed the President because he regarded him as "an enemy of the good people—the good working people," and that he was not sorry for his crime—all tend to stamp him as an anarchist. In fact, his bearing and conduct from the time of the commission of the crime to his execution were entirely consistent with the teachings and creed of anarchy. Moreover, neither the three careful personal examinations which I made of him—one alone, one with Dr. Hurd, and one with Dr. Gerin—the measurements of his body by the Bertillon system, nor the post-mortem findings, disclosed the slightest evidence of mental disease, defect, or degeneracy. This opinion is confirmed by the people's experts who repeatedly examined him and observed him from time to time, from the day of the assassination to the close of the trial, and by Dr. Gerin, the physician of Auburn Prison, who observed him carefully during the four weeks that he was in that institution awaiting execution. Dr. Gerin has had exceptional opportunity for the study of criminals, both sane and insane, in his capacity as prison physician, and previously as Assistant Physician at the State Hospital for the Criminal Insane.

If Czolgosz was a victim of mental disease, the question would naturally arise as to what form of that disorder he was suffering from. If, in answer to this question, we undertake to make a diagnosis by exclusion, we find the following results: There was absolutely no evidence of insane delusion, hallucination, or illusion. There was none of the morbid mental exaltation or expansiveness of ideas that would suggest mania in any form, none of the morbid mental gloom and despondency of melancholia, none of the mental weakness of dementia, none of the conjoined mental or motor symptoms that are characteristic of paresis, nor was there anything in his manner, conduct, or declarations that would suggest the morbid vanity and egotism, the persecutory ideas or the transformation of personality which usually characterize paranoia or systematized delusional insanity. In fact, at no time during the period from his arrest to the time of his execution did he exhibit any of the mannerisms—boastful display, etc., or claim to have a "divine inspiration" or a "mission"—or make any complaint or suggestion of personal wrongs and persecutions which are so characteristic of paranoiacs; nor did he, during his trial, or subsequently, evince any indication of satisfaction or delight at being the central figure of the occasion, and the observed of all observers, which he was; nor was there any attempt on Czolgosz' part to simulate mental disease. The refusal to talk with his counsel was perfectly consistent with the views which he expressed to the District Attorney soon after his arrest, namely, that he did not believe in law, and that he wanted no counsel. He did, however, converse with others, namely, the District Attorney, from time to time before his trial, also with his guards at the Buffalo jail, with whom he frequently walked in the corridor fronting his cell for an hour or two at a time, conversing with them intelligently the while, and making his wants as to bathing, toilet, tobacco, etc., known in a natural manner. He also conversed freely with the people's experts in their earlier examinations of him, and talked, though not so freely, with Dr. Hurd and myself, and when, on arraignment for trial and formally asked to plead, he promptly arose from his chair and answered in a clear voice, "guilty." He also responded promptly when directed by the clerk of the court to "stand up and look upon the juror," as each of the jurors were sworn, and resumed his seat in each instance at the proper time. Beyond this he remained mute while in the court-room, and yet to any one who observed him closely it was apparent that he was fully aware of, and attentive to, the proceedings.

A recent writer—an eminent alienist—discussing the mental state of Czolgosz, says:*

"We can perceive no indications of mental disease in Czolgosz, and were the absurdity of his statements and acts to be a criterion of mental unsoundness, we should have to establish a new category of insanity for the reception of the various groups of anarchists —not to mention other terrorists.

"We deem it an error to regard Czolgosz' mutism in court, when called on to plead, and before his counsel as an attempt to simulate insanity. This conduct is in line with his rôle expressed in the theatrical declaration: 'I am an anarchist and have done my duty.' As it was his 'duty' to slay the President, so it was his duty to go to death with his lips sealed; and with this intent, the plea of guilty and his conduct are perfectly consistent. He shows no reluctance to converse on matters disconnected from the crime, nor even of matters connected therewith, provided they do not touch its preparations and thus betray his associates."

Aside from his reticence to his counsel there was nothing in Czolgosz' manner, appearance, or declarations that was indicative of insanity or of simulating. His reticence toward his counsel, as already intimated, was entirely consistent with his expressed disbelief in government and in law, and his declaration that he shot the President with a clear knowledge of the nature and consequences of the act; and while he pleaded guilty in court—and also proclaimed, when he went to his death, his reason for committing the crime, and declared that he was not sorry therefor, in a manner which clearly implied that he regarded the act as a justifiable one—he did not claim that it was not a crime on his part as paranoiacs usually do, nor did he in any way indicate that he regarded himself a victim of conspiracy or persecution. On the contrary, he declared—to the people's experts—that he fully understood what he did when he shot the President, and was willing to take the consequences; that "I know what will happen to me—if the President dies I will be hung." Justice White, commenting on Czolgosz' plea of "guilty," when arraigned for trial —a plea which could not be accepted under the law —said: "The prisoner's plea of guilty indicates that he himself anticipates no escape from the penalty which the law prescribes for a crime of the character alleged in the indictment." Again Czolgosz said: "I done my duty, I don't believe in voting; it is against my principles. I am an anarchist." He further said that he had been an ardent student of the doctrine of anarchy, and had attended many "circles," where these subjects were discussed. He had attended a meeting of anarchists "about six weeks ago," and also in July; had met and talked with an anarchist in Chicago about ten days ago; that he belonged to a "circle" in Cleveland which had no name. "They called themselves anarchists." That he went to Cleveland "on no particular business" the Friday before the assassination. He had been in Buffalo for two or three weeks prior to going to Cleveland. "I planned to kill the President three or four days ago, after I came to Buffalo—from Cleveland—I don't believe in the republican form of government, and I don't believe we should have any rulers. I had that idea when I shot the President, and that is why I was there."

In explanation of his abandonment of his religious faith and his rejection of the services of a priest, Czolgosz said the night before his execution, "I would like the American people to know that I had no use for priests. My family are all Catholics and used to go to church until the hard times of 1893. We had been taught by the priests that if we would pray, God would help us along, but it did no good; it didn't help us, and we stopped going to church at that time." He also said at this interview: "McKinley was going around the country shouting prosperity when there was no prosperity for the poor man. I am not afraid to die. We all have to die sometime."

It may be said that Czolgosz' belief which he expressed as he went to his death, that the President "was an enemy of the good working people," was a delusion, and such it undoubtedly was in the broadest sense of that term, that is, it was a false belief, but it was in no sense an insane delusion or false belief due to disease of the brain. On the contrary, it was a political delusion, so to speak—a false belief founded on ignorance, faulty education and warped, not diseased, reason and judgment—the false belief which dominates the political-social sect to which he belonged and of which he was a zealot, who in common with that kind believes that all forms of government are wrong and unnecessary—a body of malcontents whose teachings oppose all government and who advocate the use of violence to destroy the existing social and civil order of things. By his own admissions, Czolgosz was a devout anarchist and a firm believer in the principles of "Free Society" as taught by Emma Goldman—of whom he was an ardent admirer—and others. These were the beliefs which furnished the motives for the murderous deed.

---

* "The Mental Status of Czolgosz and Assassins Generally." By E. C. Spitzka, M.D. *The Medical Critic*, November, 1901.

That Czolgosz was an anarchist and actuated in his crime by the motives which spring from the teachings of that sect are clearly shown by (1) His declarations after his arrest, namely, that he did not believe in any form of government or law, and that all rulers were tyrants who ought to be put down. (2) His admissions to the District Attorney that he was a member of anarchistic societies or circles, and had frequently attended the meetings of the same; also that he had been influenced in his views by the "lectures" of Emma Goldman, and that when apprehended anarchistic literature was found on his person, and (3) The recognition and commendation which he has received at the hands of anarchists at their meeting, both in this country and abroad, since his death, several of these societies having openly recognized him as such and lauded his action.

The anarchists' creed teaches that when one of their number is selected to do a certain deed, he is to proceed about it quietly and in his own way, taking no one into his confidence; that, having accomplished the deed if apprehended, he shall not admit his connection with any other members of the circle; that, if convicted and sentenced to die, he shall go to his death without revealing his connection with others, resting secure in the belief that he will be ever regarded by his associates as a martyr and a hero, who died in the discharge of a noble duty. The course and conduct of Czolgosz from the beginning down to his death are entirely in keeping with this creed. And finally, the cool and courageous manner in which he met his death, and the fact that from the day of his arrest until he died, he never uttered a word that could be used against his accomplices—if he had any—and that he died—as anarchists who suffer the death penalty always die—without uttering a word that would tend to incriminate any of his co-conspirators, all tend to stamp him as an anarchist.

In conclusion, the writer, having viewed the case in all its aspects, with due regard to the bearing and significance of every fact and circumstance relative thereto that was accessible to him, records his opinion unqualifiedly that Leon F. Czolgosz on September 6, 1901, when he assassinated President McKinley, was in all respects a sane man, both legally and medically, and fully responsible for his act.

85 Madison Avenue.

The Violet Cure for Cancer.—It is said that a test of the recently revived violet-leaf cure for cancer is to be made in Baltimore. The patient is a woman in the University Hospital suffering from an inoperable carcinoma of the breast.

THE POST MORTEM EXAMINATION OF LEON F. CZOLGOSZ.

By EDWARD ANTHONY SPITZKA

NEW YORK

COLLEGE OF PHYSICIANS AND SURGEONS

The post-mortem examination was performed by the writer under the supervision of Dr. Carlos F. MacDonald of New York, who was requested by the State Superintendent of Prisons to take medical charge of the execution in conjunction with Dr. John Gerin, prison physician. The examination began at 7.50 A.M., and was completed at 12.30 P.M. Among the witnesses were the physicians in attendance at the execution.

As the body lay upon the table in the dorsal position, the right leg, to which the electrode had been attached, was slightly flexed, and a trifle abducted. This attitude of the body has been found to be uniform in the post-mortem examinations made on many other electrocuted criminals by Dr. Ira Van Gieson. In all of these cases the electrode had been applied to the knee flexure.

Corresponding to the attachment of the leg-electrode there was a superficial blistering, with some desquamation of the epidermis and some œdema. At the site of application of the head-electrode there were only a few signs of vesication, limited to the occiput.

Post-mortem discolorations existed in all the extremities, but not in the trunk, head, or neck, where the skin was fairly white. There was post-mortem lividity of the toe- and finger-nails. The pressure of the straps had not produced any discolorations. There was a discharge of small amount from the urethra, probably of seminal fluid.

The assassin's physiognomy may be described as youthful and with rather a pleasant expression. The nose is pointed, slightly retroussé, and fairly straight, deviating a little at the point of the injury inflicted at the time of the assassination. The eyes are blue, the pupils equal and moderately dilated. The hair is a light brown and slightly curly. The face is oval and symmetrical. The ears are well formed and absolutely symmetrical. The mouth is well-shaped; the lips full, measuring the true orifice, the width is 4 cm., between the outer angles 5 cm. The teeth are of normal shape, but are in poor condition. The external genitals are normal, and are unclean with accretions of smegma under the prepuce. There are two flat cicatrices—one 4 mm. in diameter, the other half as much—on the mucous surface of the prepuce, about 5 mm. from the corona glandis. The tissues under and about these cicatrices are not indurated, and the scars are doubtlessly the remains of chancroids acquired at some time previously. As stated before, there has been a discharge of seminal (?) fluid, some of which is still within the urethral passage.

At 8.10 A.M., the surface temperature of the body, taken on the side of the chest with a "Seguin" surface thermometer, was 97° F.; per oram, 97°.

The body cooled very slowly throughout the examination, and the greatest amount of heat appeared to be retained in the brain. Rigor mortis set in about three hours after death.

The following measurements of the head were recorded.

	CENTIMETERS.
Max. circumference (21½ inches)	54.6
Max. antero-posterior diam. (from glabella to max. posterior point)	18.7
Max. lateral diam.	15.5
(Cephalic Index=82.88)	
Biauricular diam. (between roots of zygomæ)	15.0
Length of face (from the intersuperciliary point to the superior alveolar point between the middle incisors)	9.2

	Centimeters.
Bizygomatic diam	14.5
Min. frontal diam	12.0
Diameter from glabella to inion	19.1
From vertex to hair-line	12.0
From hair-line to root of nose	6.0
From root of nose to its base	5.3
From base of nose to chin	7.0
Vertex to chin (diameter)	25.4
Breadth between pupils of eyes	6.8
Breadth of nose at its base	3.4
Width of mouth (internally)	4.0
Width of mouth (externally)	5.0
Length of ears (both sides equal)	6.1

After these measurements had been taken, about fifty minutes were devoted to the making of plaster molds of the entire head.

A cast has since been made from these molds, and two photographic views, in full face and in profile, are presented here. Unfortunately the left ear in the mold had been broken during transportation from Auburn, and the fragments were pieced together with difficulty. The defects have been rectified in the photograph. On the subject, the ears were perfectly symmetrical, both as to form and size.

The molds were made upon the head, while the body lay prostrate upon the table. This attitude gave rise to the prominence of the "Adam's apple," and to the slight parting of the lips. The hair was rubbed well with vaseline, and flattened as much as possible, to prevent the plaster from adhering.

On the skull the following measurements were taken:

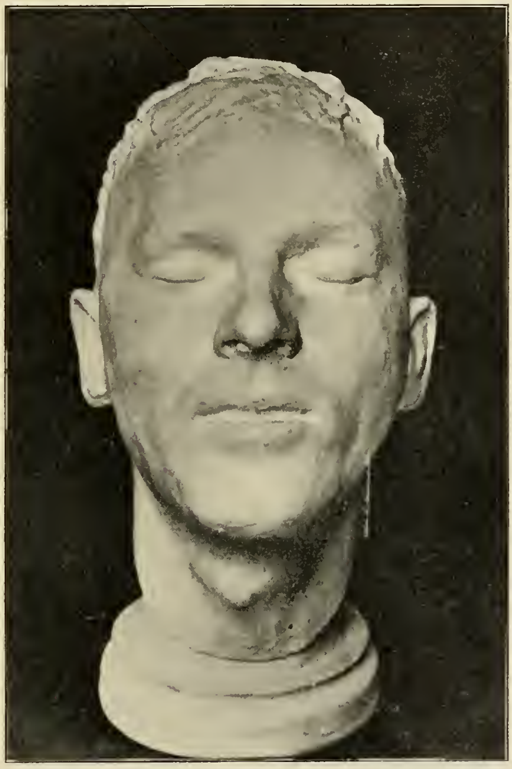
	Centimeters.
Max. antero-posterior diam	18.0
Max. lateral diam	14.7

(Cranial Index=81.66.)

The head of Czolgosz, as is typical of the Poles, falls into the sub-brachycephalic class; according to Weisbach, the cephalic index of forty Poles was 82.9 82.88 in Czolgosz).

At the time of Czolgosz' reception at the Auburn State Prison (September 27), measurements of his body were taken according to the Bertillon system by J. N. Ross. I reproduce here the more important figures:

	Centimeters.
Stature (5 ft. 7½ in.)	171.4
Stretch	181.0
Trunk	91.1
Head, length	18.6
Head, width	15.6
Cheek width	14.5
R. ear, length	6.3
L. foot	26.0
L. Mid. F.	11.7
L. Lit. F.	9.0
L. Cubit	47.2



Photograph of a cast of the head, from plaster molds made by the writer soon after death.

Defects.—Unfortunately, the left ear in the mold had been broken in transit, and the fragments were pieced together with difficulty. The defects were rectified in the photograph. On the subject, the ears were absolutely symmetrical.

"These measurements are all medium, and each is consistent with the others. The stretch and cubit measurements might be said to be slightly out of proportion, indicating that his forearms were slightly longer than those of a majority of men of his stature, but this excess of length is not sufficient to call for comment."

His weight on that day was 141 pounds.

The marks and scars are here reproduced in the order in which they appear on the prison department's identification card.

"I. Sev. sm. cics. post. first finger, left hand near 2d joint. Cic. of 1 ob. ex. on 1st Phal. third finger left hand post.

"II. Cic. of 3 rec. ver. crossing third joint, mid. fgr. right post. Cic. of 1 circ. at 5 over right wrist post.

"III. Mole at 5 under left cheek-bone and 9 to left med. line.

"IV. Sev. moles on front and back of neck."

Next the cranium was opened and the brain removed. The scalp was divided by means of a median incision passing from the glabella to the inion. On incising the scalp, a quantity of dark fluid blood escaped. The scalp was of moderate thickness, firm and well adherent to the skull. The two flaps of the scalp were dissected from the skull, and drawn down on either side of the head. The sutures were well-marked, and no synostosis was observed. Supernumerary or abnormally developed bones were not discernible.

The calva was removed by a saw-cut passing around the cranium, about 1.5 cm. above the glabella and about 2.5 cm. above the inion. In Fig. 7 is shown the outline of the thickness of the skull along this section. In the removal of the calva, the saw was supplemented by the chisel and hammer. The calva came off readily, the dura being non-adherent. There was no marked escape of cerebrospinal fluid. Along the saw-cut the skull was slightly flatter in the frontoparietal region on the right side, while it was more curved or rounded on the left. The right parieto-occipital region was a trifle fuller than on the left side. The markings on the internal surface of the calva, such as the groove for the suparietal longitudinal sinus and for the meningeal vessels, the digitations, and the depressions for the Pacchionian bodies, etc., were all distinctly marked. The dura was grayish-white, moderately translucent and somewhat dry; there existed a marked engorgement of dark fluid blood. The dura was neither tense nor loosened. The Pacchionian bodies were of the usual number and distribution. The inner surface of the dura was fairly moist. There were no evidences of hemorrhage, pigmentation or of pachymeningitis.

The brain invested by the pia-arachnoid was exposed by crucial incisions into the dura, which was perfectly nonadherent to the membranes within. The brain was carefully removed, and during most of the subsequent examination was kept in a salt solution (about 1 part in 20 of water). At the time of removal, still invested by the pia-arachnoid and with the ventricles unopened, the entire brain weighed fifty-one and a half ounces avoirdupois (1,460 grams).

The base of the skull was normal in every respect.

The pia-arachnoid was of normal thinness, and devoid of opacities or other signs of disease past or present. The only unusual appearance was an injection of bright red blood in the finer vessels of the pia, due if we may judge from previous reports of autopsies on electrocuted criminals, to the high electromotive force exerted by the fatal current in this part of the body. The pia was stripped off with ease, being nowhere adherent to the cortex.

Profile view of the plastercast.

Examination of the Brain.—In general, the brain presents no marked peculiarities of shape or size. It is firm to the touch, and no portion of it, despite most careful examination, feels softened or indurated. (Figs. 1, 2, 3 and 4.)

The brain was divided into its natural segments according to the following method: The ectal border of the optic tract and the tænia thalami ("ripa" of Wilder) are used as guides for a single simple incision; those of either side converge cephalad to meet in front of the chiasm; the usual cut through the callosum and the terma (lamina terminalis) completes a tri-section which leaves the cerebrum (prosencephal) and brain-axis separated as nearly the ideal as can be. This mode of dissection is a modification of Meynert's plan, and is a method by which each hemicerebrum, with the insula intact, is separated from the brain-stem; whereas, Meynert, by trenching round the circumannular boundaries, separates the convex cortical mass from the brain-stem plus the insula, leaving a cortical component attached to the axial structures. The Meynert method consequently does not give the weight of the cerebral hemispheres strictly speaking. As far as the caudatum and lenticulare are concerned, this would not be a serious objection, but as it also excludes the important cortical area of the insula—no inconsiderable portion of the cerebral projecting and associating tracts—it falls short of the method adopted here.

After the brain had been thus dissected and drained and the pia-arachnoid stripped off the cerebrum, the segments were found to have the following weights:

	Grams
Left hemicerebrum (without pia)	5[illegible]
Right hemicerebrum (without pia)	6[illegible]
Cerebellum (with pia-arachnoid)	166
Isthmus (with pia-arachnoid)	64
	1,45[illegible]

or a trifle less than 50 ounces.

Examination of the paracœles (lateral ventricles) in both hemicerebra revealed the veins of the striatum (the striatal veins) injected with deep violet-colored blood. The cornua were of normal extent and conformation throughout. The endyma was smooth, the choroid plexus was normal and contained little blood; the velum interpositum ("velum" of Wilder) was normal.

Description of the fissures and gyres:

Left Hemicerebrum.—The sylvian fissure is 6½ cm. in length, the episylvian, 2¼ cm.; the hyposylvian is absent. The presylvian ramus is 2 cm. in length, the subsylvian 1 cm. in length.

The central fissure is fairly flexuous and ramified; it is uninterrupted throughout its length, and is separated from the sylvian by a narrow isthmus. At its ventral end the fissure terminates in a hook-like manner. The dorsal end appears on the mesial surface. The supercentral fissure is confluent with the superfrontal, but is separated from the precentral. The superfrontal is distinct in the mid and postfrontal regions, but is absent in the prefrontal regions. The three-tier type is preserved in the prefrontal region by the existence of a medifrontal fissural segment about 4 cm. in length, and which is confluent with the orbitofrontal. This is not very clearly seen in the figure, owing to the effect of the convexity. The reader is referred to the schematic outline in Fig. 8.

The precentral fissure is confluent with a small diagonal fissure, and this in turn with the presylvian.

It sends an "anterior precentral ramus" across the medifrontal gyrus to anastomose with the superfrontal fissure.

The subfrontal fissure is independent and sends off several rami into the neighboring gyres. There is a long radiate fissure.

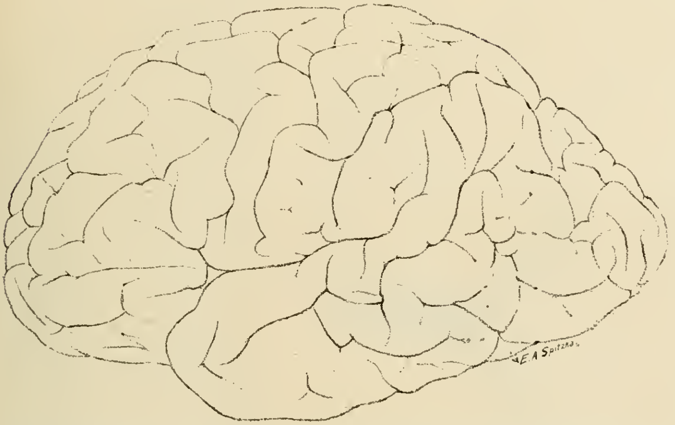


FIG. 1. Lateral view of the left hemicerebrum of the assassin Czolgosz. This drawing, as were the others of the brain, was made from the fresh specimen immersed in a salt-solution. Although the author cannot aver photographic accuracy, these drawings show the disposition of the fissures and gyres in a fairly correct manner.

The precentral gyrus is not very broad as compared with the postcentral. The three frontal gyres are fairly massive and marked by fissures which run generally transverse.

The postcentral fissural complex consists of three segments. The dorsal one is very flexuous and ramified, but independent. The middle segment is confluent with the parietal, and is only superficially joined to the third segment, the subcentral. The transpostcentral is hardly visible on the external surface, but on examination is found to communicate with the circuminsular fissure.

The parietal fissure is notable for the angle which it makes with the intercerebral cleft, converging rapidly toward it as it passes caudad. It communicates with the paroccipital fissure over a vadum about 6 mm. in depth. Otherwise the paroccipital does not communicate with any other fissure. There are two transparietal fissures; the cephalic one communicating with the precuneal fissure on the mesial surface.

The temporal lobe is of good size and shape. The supertemporal fissure is uninterrupted throughout its length, and communicates with the intermedial over a slight vadum. The meditemporal fissure is represented by four segments. Numerous fissures, the "lateral occipital" among them, mark the region of the occipito-temporal transition. The post-calcarine fissure appears on the lateral surface for about 2 cm.

The postcentral gyrus is of good development and is fairly wide. The marginal, angular, and postparietal gyral portions of the subparietal lobule exhibit a moderate development. The parietal gyrus is of cuneiform shape, broad cephalad, narrow caudad. The supertemporal gyrus is very sinuous. The remaining temporal gyres are fairly wide and well developed.

The subcalcarine gyrus is wide in its caudal portion. The cuneus is small, rather unusually so. The precuneus is of good size and conformation. The paracentral gyrus is of typical appearance and of the usual size. It is traversed by a well-marked inflected fissure and by a tri-radiate intraparacentral fissure. The mesial surface of the superfrontal gyrus is of moderate size and is marked by five or six transverse fissures, three of which are rami of the supercallosal. The callosal gyrus in its cephalic half is doubled by a long fissure running parallel with the supercallosal; in its caudal part it is traversed by several transverse fissures.

There are two well-marked rostral fissures (rostral and subrostral) and a short transrostral. The supercallosal fissure is long and anastomoses with the paracentral over a vadum of 5 mm.

The paracentral fissure in turn anastomoses with the precuneal over a vadum of 3 mm. The occipital and calcarine fissures anastomose freely. A "posterior cuneolingual" subgyrus tends partially to separate the calcarine from the postcalcarine. The collateral fissure is fairly well ramified.

The insula exhibits a good development. There are six gyres proper, with seven peri-insular digitations. The insula was completely covered by the opercula.

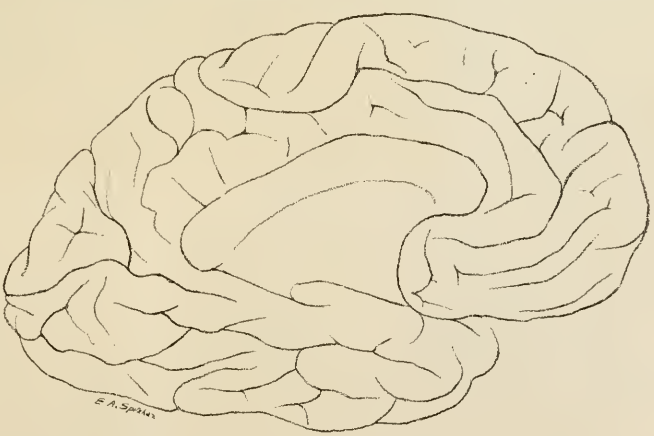

FIG. 2. Mesial view of the left hemicerebrum.

Right Hemicerebrum.—The sylvian fissure is 5½ cm. in length; the episylvian, 3 cm.; the hyposylvian, 1½ cm.; the presylvian, 2½ cm.; the subsylvian is very short. The central fissure is uninterrupted throughout its length, and is separated from the sylvian by a very narrow isthmus. Its dorsal end crosses the dorsi-mesal margin. The supercentral fissure anascommunicates with a long superfrontal fissure but not with the precentral.

The precentral fissure joins both the transprecentral and the diagonal, and by means of these the sylvian cleft.*

This fissure gives off an "anterior precentral ramus," from which springs the caudal segment of the subfrontal fissure.

The superfrontal fissure is long and uninterrupted, extending nearly to the frontal pole. There is no true medifrontal fissure present. The subfrontal fissure is in two segments, the caudal segment being confluent with the precentral by means of its "anterior ramus," the cephalic segment anastomoses with the orbito-frontal. Besides an independent radiate fissure, there are other unnamed fissures in the subfrontal region. There are two long sagittally directed orbital fissures; the lateral one of these communicates with the orbitofrontal.

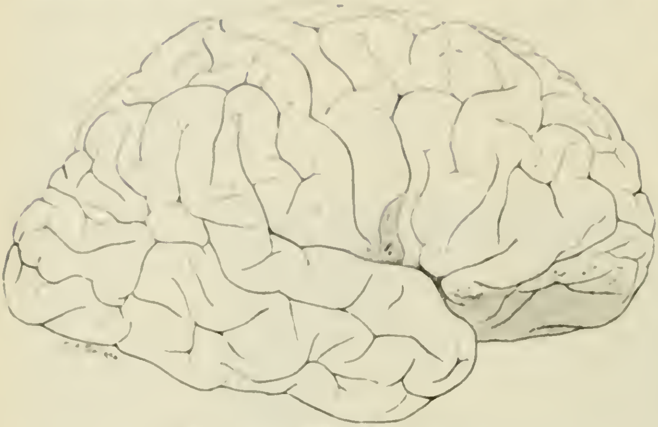

Fig. 3. Lateral view of the right hemicerebrum.

As in the left half, the precentral gyrus is rather narrow as compared with the broader postcentral gyrus. The three frontal gyres are all of good width and are chiefly marked by transverse fissures.

The postcentral fissural complex is made up of two segments superficially confluent with each other. The dorsal segment is short. The ventral segment is longer, and is confluent with the parietal fissure. The parietal fissure is uninterrupted, deep, and separated from the paroccipital fissure by an isthmus. There is a well-marked post-paroccipital fissure, and one distinct transparietal.

The subtemporal fissure is long, uninterrupted, and not deeply confluent with any other fissure. There are four meditemporal fissural segments. The intermedial joins the parietal. There is a fairly well-marked "lateral occipital" fissure.

The postcentral gyrus is fairly wide and flexuous. The parietal gyrus is wide and exhibits the same transform shape as described for the left side. Of the subparietal gyres the angular gyrus is of fair size, while the remainder of this territory shows only a moderate development. The paroccipital gyrus is very small, but quite flush with the general surface of the brain.

The gyres of the temporal lobe show very good development, and in the occipito-temporal transition the markings are quite complex.

On the mesial surface the supercallosal fissure consists of two segments and there is a similar duplication of the callosal gyrus (in its cephalic portion) as has been described in the left half. A notable peculiarity consists in the confluence of the inflected fissure with the paracentral stem, while the cephalic paracentral limb is separated from its stem, but is joined to the caudal end of the supercallosal. There is a triradiate intraparacentral. The precuneal fissure would be independent, but for a superficial junction with the paracentral.

The occipital fissure is deeply confluent with the calcarine. The postcalcarine is triradiate and separated from the calcarine by a "posterior cuneolingual" isthmus.

The superfrontal gyrus is fairly well marked by many transverse fissures and by two long and distinct rostral (rostral and subrostral) fissures. The precuneus is large, a little larger than its fellow on the left side. The cuneus is as small as on the left half. The subcalcarine gyrus is of considerable width in its caudal portion.

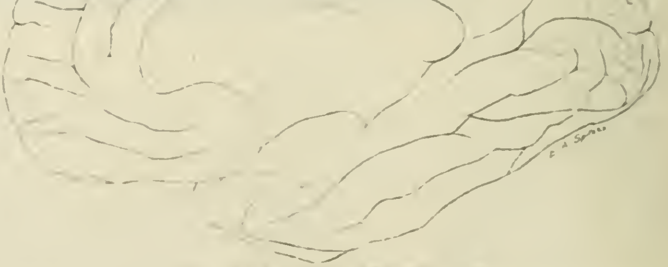

Fig. 4. Mesial view of the right hemicerebrum.

The insula presents an ordinary degree of development, and, as on the left side, possesses six gyres, with seven peri-insular digitations.

Sections of the Brain.—In cutting the brain, the resistance to the knife suggested neither increased nor diminished consistence. The cut surface was moderately moist, the gray, as well as the white, matter was of normal color, the cortex was of the usual thickness, and there existed neither anæmia nor hyperæmia. No hemorrhages, sclerotic patches, neoplasms, or other lesions were discoverable.

---

*Found by Sernoff in 40 per cent of Polish brains.

The basal ganglia, crura, cerebellum, pons, and oblongata were all perfectly normal, there being even an absence—so far as the naked-eye examination could determine—of the small hemorrhages in the floor of the fourth ventricle, which have been usually found in electrocuted criminals.[2]

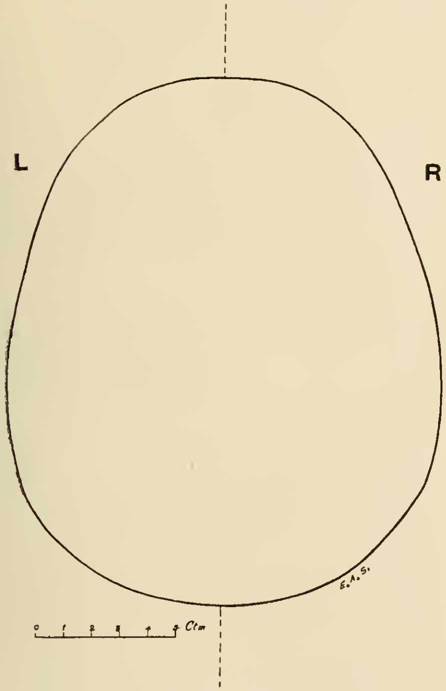

FIG. 5. Horizontal outline of the head (by lead-strap).

The spinal cord was not examined.

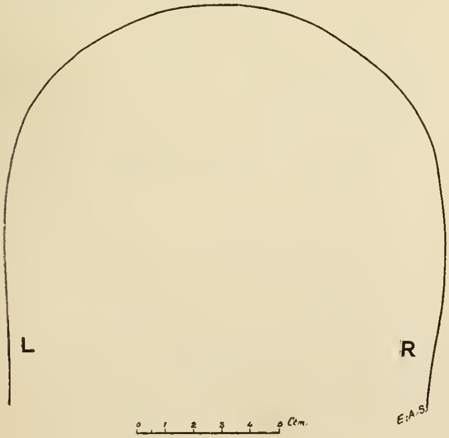

FIG. 6. Outline over the vertex, from ear to ear (taken just in front of the roots of the zygomæ).

Examination of the Thorax and Abdomen.—An incision was made from the top of the sternum to the pubic symphysis, a quantity of dark fluid blood escaping. The diaphragm was found attached to the sixth rib on both sides of the sternum. About three to four fluid drachms of clear fluid were found in the pericardial sac. The heart was firm and appeared to be in a tetanized condition; it had ceased in systole.

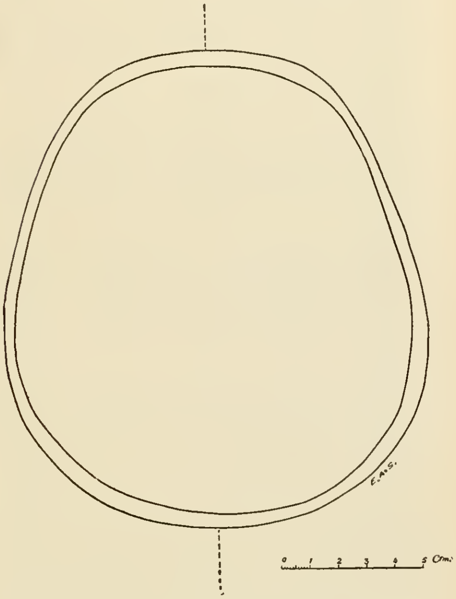

FIG. 7. Outline drawing of the skull in the plane of the saw-cut described in the text, showing the thickness of the bones.

This contracted condition of the heart is doubtlessly due to the high electromotive force of the fatal current. The ventricles were empty; the heart walls, endocardium, and valves were normal. The weight of the heart was eleven ounces. Both lungs were somewhat emphysematous, floating a trifle more than half out of water. They were moderately pigmented and of firm consistency. None of the bronchial lymph nodes were enlarged. Except for a few bands of pleuritic adhesions of the right lower lobe, there were no lesions in either lung. The left lung weighed 7¾ ounces, the right lung 8½ ounces.

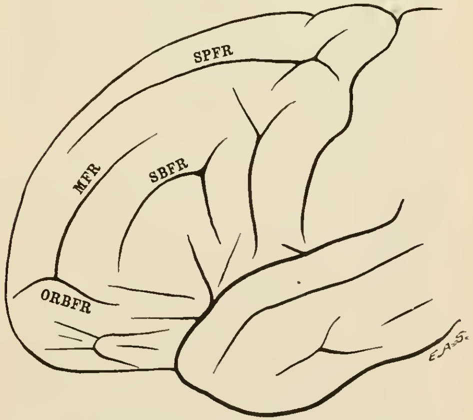

FIG. 8. Diagrammatic sketch, showing disposition of the fissures and gyral tiers in the frontal lobe of Czolgosz.

The larynx, aorta, and the venæ cavæ were normal.

The stomach was in a normal position, well contracted and well under the diaphragm, with only a small residue of food near the pyloric end, the prisoner having had nothing to eat since the evening before the execution.*

The examination of the intestines was a brief one, as nothing unusual was seen. The appendix was 8 cm. in length, free, and lay dorsad and mesad of the cæcum.

The pancreas was normal.

The liver was dark, hyperæmic, but healthy; there were no patches, infarctions, or other lesions. The gall-bladder contained about one ounce of clear bile. The liver weighed 61 ounces.

The spleen was also hyperæmic, mottled with light pink streaks, but of normal structure. Weight 7½ ounces.

The kidneys were moderately supplied with fat, markedly hyperæmic, but all the structures could be made out clearly to be of normal condition. The left kidney was somewhat larger than usual. The capsule was non-adherent in both instances. The left kidney weighed 7½ ounces, the right weighed 5½ ounces.

The bladder was somewhat contracted, firm, and contained about three ounces of clear urine. The bladder wall and mucous membrane were normal in all respects. The prostate was rather firm, but not enlarged. The urethra, testes, etc., were normal.

It had been the writer's purpose to make a fuller anatomic and anthropometric investigation upon the assassin, but the peculiar circumstances which arose in the matter of the disposal of the body, and the anxiety of the prison's warden to put the body under earth, forced me to conclude my researches after having obtained the most essential data for purposes of record and future study.

The results of the necropsy can be summed up by saying that Czolgosz was in excellent health at the time of his death. There was, of course, a marked condition of hyperæmia of all the viscera, and the blood was considerably altered in that it remained fluid, doubtlessly due to the destruction of the fibrin ferment, or of the fibrinogen, or both. These phenomena, as also the seemingly tetanized condition of the heart, have been observed by E. C. Spitzka, Carlos F. MacDonald, VanGieson, and E. W. Holmes[3] on criminals executed by lethal currents of electricity.

The external appearances of the body of the assassin, especially the facial expression, have been admirably described by Murat Halstead, who happened to be present, in a short but vivid account of the autopsy entitled "Czolgosz After Death."

"The spectacle was interesting; the assassin had been dead but a few minutes, and was lying at full length on his back on the table provided for the surgeons, his body white as marble, his face not at all disturbed. One might say he was as if sleeping, but that would not describe the expression of the features, though that was almost of perfect repose. The head rested on the back part of the table so as to elevate the chin and allow the forehead to slope downward. There was no sign of a great agony; the hair had not been removed for the electrode, but was full of water from the sponge, and in disorder. If there was any mark on the head made by the deadly shock it was not visible. There was a red blotch on the right leg below the knee. . . . The strong throat, with a distinct "Adam's apple," was prominent. The lips were slightly parted with more than the curl they had in life. . . . There was nothing in the appearance of the body of the emaciation from imprisonment so often referred to. Any physician would say the corpse was that of a well-nourished young man. The figure was of good proportions, the limbs especially so. The arms were not muscular. Evidently he was not a man who had cultivated his muscles by exercise or expanded them by labor. The arms were of a young man of leisure—smooth, round, and fair. His hands were not in any way notable. He had high insteps, neat ankles, and long toes. The muscles of the legs were better developed than those of his arms, indicating he was swift of foot. He was not noticeably spare in body; his chest was round and symmetrical—not lean, but the ribs quite distinct. With his head thrown back, it seemed to have been well poised in life, more so than is shown in his pictures—all of which that are familiar having been taken in prison. Nothing in his face or his person gave indication of heavy feeding or drinking, or of evil indulgence. There were none of the inevitable traces of confirmed dissipation."

The question as to whether his body invested a healthy mind opens up a wide topic for discussion which it is not entirely in the writer's province to pursue. So far as our knowledge of the correlation of brain-structure and brain-function extends, nothing has been found in the brain of this assassin that would condone his crime for the reason of mental disease due to intrinsic cerebral defect or distortion. The brain-weight, though by itself unimportant, when considered in its other relations, points to a good condition of the organ. Divested of its membranes, dissected, drained and after being immersed in a salt-solution for several hours, its weight was 1,415 grams, a trifle less than fifty ounces. This weight is even a little over the average. Giltchenko[4] records observations upon the weight of 102 Polish brains, the average being, for males, 1,397.8 grams, with an average stature of 168.12 cm. The development of the fissures and gyres, from a morphological viewpoint, has taken place in the direction usual in ordinary average brains. There are no marked evidences of arrested development or of pithecoidal anomalies. Generally speaking, this brain does not exhibit that especial kind of asymmetry of gyral structure in the cerebral halves that is so characteristic of the brains of highly endowed individuals. There are many features in the one hemisphere that are reproduced almost exactly alike in the other. The few peculiarities encountered in the course of the fissures, such as the confluence of the left precentral, by its anterior ramus, with the superfrontal—across the medifrontal gyrus, or the separation of the right cephalic paracentral limb from its stem, while at the same time the inflected joins the paracentral (a feature found by the writer in nine out of 160 hemicerebra in which the inflected was present)[5] and also the smallness of the cuneus—are insignificant so far as individual brains are concerned, and will be discussed at length in a later contribution.[6]

The skull is not symmetrical, but the asymmetry is slight and fully within the normal range of variation. An absolutely symmetrical skull probably does not exist.

It is a probable fact that certain oft-mentioned aberrations from the normal standard of brain-structure are commonly encountered in some criminal or degraded classes of society, and those who have attempted to found a school of degeneracy have endeavored to explain crime and social wickedness as due to the "accidental persistence of lower types of human organization." But these structural anomalies, so far as they have been described in the brains of criminals, are too few and too insufficiently corroborated to warrant us in drawing conclusions from them. Various perversions or anomalies of mind

*The "hearty breakfast" so graphically described in most newspapers was but a figment of the imagination.

may exist in this class without presenting a uniform criminal type, either from the sociological or the anatomic aspect. Of course, it is far more difficult—and it is impossible in some cases—to establish sanity upon the results of an examination of the brain than it is to prove insanity. It is well known that some forms of psychosis have absolutely no ascertainable anatomical basis; and the assumption has been made that these psychoses depend rather upon circulatory and chemical disturbances. So far as this question touches upon the brain and body of Czolgosz, there have been found absolutely none of those conditions of any of the viscera that could have been at the bottom of any mental derangement. Taking all in all, the verdict must be, "Socially diseased and perverted, but not mentally diseased." The most horrible violations of human law cannot always be condoned by the plea of insanity. "The wild beast slumbers in us all. It is not always necessary to invoke insanity to explain its awakening."

In conclusion, the writer wishes to express to Dr. Carlos F. MacDonald his appreciation of and thanks for the exceptional opportunity afforded in the performance of this autopsy.

A CASE OF FACIAL HEMIATROPHY.

By LOUIS F. FRANK, M.D.,
MILWAUKEE, WIS.

The case I am prompted to report is one of such great rarity that this feature alone may truly claim our interest. While our knowledge regarding linear atrophies of the skin, striæ atrophicæ, is quite complete, and many cases have been reported in which nervous disturbances have resulted in more or less atrophy of the skin, the cases of so-called idiopathic atrophy are very rare, and little is known of their pathogenesis.

The patient is an unmarried woman of about twenty-four years of age, of healthy parentage without hereditary taint, excepting one sister who died of tuberculosis. Her father and mother are fifty and fifty-two years old, respectively, are in good health, as are also four brothers and five sisters. When thirteen years old, she was taken ill with scarlet fever, accompanied by an unusually severe angina. She has never suffered from any nervous affection, nor has she had any symptom pointing to nervous exhaustion. Her health seems to be perfect, excepting a condition and appearance of anæmia. At the age of nineteen the present disease began to show itself on the forehead of the left side of the face in the formation of pigmented patches accompanied at their appearance with considerable pruritus. At present the most conspicuous and noticeable feature of the malady is the presence of irregularly distributed patches of chloasma below the general level of the integument of the left side of the face. This symptom is especially prominent on the forehead, the atrophic and pigmented area extending from the base of the nose about an inch into the scalp, rendering the portion affected hairless. One rather deep-running sulcus marks the median line of the forehead and the chin. A similar scleroderma-like patch, also pigmented, is noticeable in the temporal region, and from the malar bone prominence to the angle of the mouth. Irregularly defined chloasma spots mark the left side of the neck. The disease began visibly with the appearance of the pigmentation on the forehead, spreading thence to the lower portions of the face and attended by considerable itching, tingling, and burning, accompanied by gradual atrophy of the part affected. There is no dilatation of capillaries. The tip of the nose and the left half of the upper lip are drawn toward the affected side, as is also the muscular part of the left side of the chin, undoubtedly due to traction on the parts from atrophy of the adipose element of the integument.

I am indebted to Dr. Carl Zimmermann for the examination of the patient in regard to her nasopharyngeal, laryngeal, ophthalmological, and aural condition, and the following description of the changes noted:

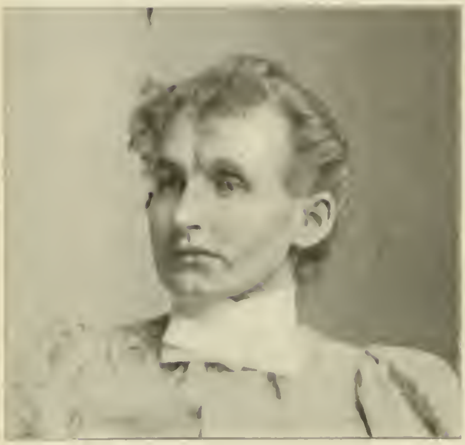
Nose.—The cartilage of the left ala nasi is so atrophic that it feels flabby, as if it consisted only of skin. The left nostril shows no irregularity, but the left choana reaches up higher than the right. The left side of the palate also shows a little higher arch than the right. The left faucial tonsil is hyperplastic. The left half of the tongue is atrophic, and so is the left lingual tonsil, so that the left side of the anterior surface of the epiglottis is more open to view than the right; the space between tongue and epiglottis being larger on the left than on the right side; the larynx shows no asymmetry.

Eyes.—The surface of the left upper lid is smooth; its fold is entirely gone. Instead of a convexity below the supraorbital margin and above the eyeball, due to the support of the latter, there is a deep excavation on the left side. The left upper and lower tarsi are thinner than the right, and the eyeball is therefore felt nearer to the finger through the closed lids. Intraocular tension is diminished on left side. The left caruncle and semilunar fold are sunk back, and in closing the eye the lacrymal canaliculi leave a space between each other, but the palpebral fissures are equal. The lashes and hair of the eyebrows on the left side show no difference from those on the right side. The left eyeball is not smaller, but a little farther in the orbit (enophthalmos). The scleral vessels are slightly injected. The pupils react equally and normally to light, directly and consummately, but the left pupil is a trifle wider than the right. Visual field and color perception are normal. The ophthalmoscope shows hypermetropic astigmatism, and a scleral ring about the optic disks a little more marked on left eye. The fundus shows no difference of pigmentation from that of the right eye.

Ears.—The left auricle is smaller and thinner than the right. The left vertical diameter is five-eighths inch shorter than the right; the horizontal, one-quarter inch. The cartilage of the left auricle and meatus is atrophic, and therefore the left meatus is wider. It gaps so much that the whole posterior portion, hammer, and a small portion in [illegible] of the hammer can be seen without straightening the curvature of the meatus by pulling the auricle upward and backward, and without a speculum. There is no difference in the secretion of the ceruminous glands.

Hearing.—Watch, right, one foot, left, four feet; whispered voice, right, twelve feet, left, fifteen feet. Tuning fork in front of ears better heard in left ear.

The following sketch showing inch measurements of both sides of the face will illustrate the actual difference in size of the two halves of the face.



The principal and apparent symptom in this disease is the circumscribed atrophy of the skin of the face. This atrophy begins at any part of the face, usually the forehead or cheek, accompanied by discoloration. The atrophic region is of irregular outline and growth, sometimes traversed according to location by grooves and ridges. The extent of the atrophy is variable; it may remain localized to a certain part of the face, and may even extend into the other side of the face into the scalp, neck, and ear. Sometimes only the skin is affected, usually the adipose tissue, muscles, and bones. Oftentimes the hemiatrophy extends to the cartilages of the nose, the tongue, palate, uvula, and tonsils.

Of concomitant symptoms attending the above tissue changes the most frequent are hyperæsthesia of the trigeminus, parasthesias in the region of the skin lesion, and spasms of the masticator muscles. Rarely the sympathetic, causing dilatation of the pupils and innervation of the bloodvessels of the face, is affected, but exceptionally there is lessening of susceptibility.

The hemiatrophia facialis progressiva (aplasie lamineuse progressive, trophoneurosis facialis) was first described by Romberg, and but one hundred cases have so far been reported. The disease is not known to be hereditary. All authors seem to agree as to three etiological factors: (1) Its beginning in youth (seventy-five before the twenty-fifth year, thirty before the tenth, twenty-four before the twentieth, and ten after the twentieth year); (2) The predominance of the female sex (sixty out of ninety). (3) The greater frequency of the affection on the left side of the face (fifty-three to thirty-three of the right side). In a majority of cases a peculiar sequelar connection with some infectious or contagious disease, as morbilla, angina, scarlatina, typhoid fever, pneumonia, inflammatory rheumatism, erysipelas, or abscess of teeth seems evident. Traumatic influences due to a blow received, injury to the eyeball, a fall, etc., have been mentioned in a few cases as exciting causes.

Pathologically, the results obtained are not very satisfactory, the principal post-mortem investigation having been made by Mendel (*Neurol. Centralblatt* VII, 1888), who comes to the conclusion that hemiatrophia facialis is caused by an interstitial neuritis of the trigeminus. Most observers admit the affection to be a trophoneurosis of the trigeminus, facial, and sympathetic, or a morbid condition of the G. Gasseri and sphenopalatinum, since other trophic disturbances, as herpes zoster, discoloration of the hair, neuroparalytic affection of the cornea, are known to be caused by irritation of the sympathetic. Other observers call the disease a primary atrophy of the adipose tissue *per se*, causing contraction of the elastic fibers whereby the bloodvessels and sebaceous hair follicles are mechanically compressed, leading to permanent atrophy. Professor Nothnagel distinguishes two pathogenic forms of hemiatrophia facialis: a lesion of the highest cervical ganglion of the sympathetic, through which all vasomotor fibers of the facial region pass, and an interstitial neuritis of the trigeminus, with degeneration of the descending roots of this nerve in the brain.

[illegible] Grand Avenue.

Abscess of the Liver in the Temperate Zone.—Abscess of the liver is comparatively rare in the temperate zone, especially in children, and it is also more fatal here, the diagnosis is very difficult, due to the lack of our clinical material, and the disease is thus often discovered only at the autopsy. Rumiantseff reports a case of abscess of the liver in a boy fourteen years of age. The enlarged spleen and the chills aroused the suspicion of malaria, but quinine was given without result, and the plasmodium malariæ was not found in the blood. The examination of the urine and the absence of pain upon pressure of the abdomen, gave negative results. Only at the end of the disease the appearance of jaundice and other symptoms of disease of the liver led to the suspicion of abscess of the liver, which was confirmed at the autopsy. Oddo, in view of the difficulty of diagnosing the disease, divides it into three groups: (1) Ordinary cases characterized by the predominance of local symptoms and most accessible to diagnosis. (2) Concealed forms of the disease in which the general or extrahepatic symptoms are the most pronounced; and (3) Mixed forms of the disease in which the general symptoms predominate and conceal for some time the local hepatic symptoms.—*Meditsinskoe Obozrenie.*

Hemorrhage Into the Labyrinth (Meniere's Disease).—M. G. Dadin reports a case of hemorrhage into the labyrinth. This is regarded as one of the rarest of the diseases of the ear, and in all the literature on the subject the author could not find more than twenty seven cases. The symptoms which came on suddenly were: Complete deafness, noises in the ear, headache, and dizziness. The external and middle ear being uninjured, and the structural and functional nervous disturbance having been excluded after a careful examination, the proper differential diagnosis was arrived at. The acute symptoms subsided somewhat after a few months, but all modes of treatment proved unavailable. The disease is incurable. Regarding the etiology in this case, Dadin thinks that it might have been either congestion due to the fact that the patient had to stand for several hours a day near a hot stove in a small kitchen, or it might have been a sequela of the grippe, from which the patient had suffered some time previous to the hemorrhage, the influenza poison being capable of affecting not only the nervous, but also the vascular system.—*Meditsinskoe Obozrenie.*

MEDICAL RECORD:

WM. WOOD & CO., 51 Fifth Avenue.

New York, January 4, 1902.

THE COMMUNICABILITY OF HUMAN TUBERCULOSIS TO CATTLE.

So firmly established has become the belief in the intercommunication of human and bovine tuberculosis that even the dictum of so distinguished a bacteriologist as Robert Koch has not proved sufficient to insure acceptance of the contrary view. The validity of the opinion expressed by Koch at the recent Congress of Tuberculosis held in London was at once questioned, and already the matter is being subjected to rigid scrutiny, investigations having been set in progress that, it is hoped, will solve definitely this most important problem. A long time may, in the nature of things, elapse before it can be proved that bovine tuberculosis is transmissible to human beings, but it should be a comparatively simple matter to show whether human tuberculosis can be communicated to cattle. Evidence in support of the belief that human beings may acquire tuberculosis from cattle has already been brought forward, and at a recent meeting of the Pathological Society of Philadelphia, Dr. M. P. Ravenel reported the case of a laboratory assistant who developed tuberculosis of the skin as a result of inoculation from a cow. In the cutaneous lesions were found numerous tubercle bacilli and also typical giant cells, and with some of the tissue it was possible to inoculate and develop tuberculosis in guinea-pigs. It seems almost likely that it will be found that human and bovine tubercle bacilli are identical, though representing varying degrees of infectivity and pathogenicity, or that they are, at any rate, so closely related as to be included in the same family. A small number of observations demonstrating incontrovertibly the communicability of human tuberculosis to calves has recently been reported in a preliminary communication by Professor Sheridan Delépine of Manchester (*British Medical Journal*, October 26, 1901, p. 1224). In order to insure at least an average degree of virulence on the part of the bacilli, a mixture of tuberculous sputum from six patients was employed in the experiments. With this, one calf was inoculated directly into the lung; another, subcutaneously; a third, into the peritoneum; while to a fourth was given, in two meals, milk containing ten times as much sputum as the others were given by inoculation. The first animal presented after death a generalized tuberculosis, which, it is thought, had antedated, and was not due to, the inoculation. In the second animal, marked enlargement of a gland five inches from the site of inoculation was present, without other traces of tuberculosis, while living and virulent tubercle-bacilli were found in the affected gland; but, as the bacilli injected under the skin might have been carried from the site of inoculation and remained alive without actually producing tuberculosis, this experiment is discarded, although it is in perfect agreement with the results obtained in guinea-pigs that have been proved to indicate early tuberculous infection in these animals. In the third calf no definite reaction to tuberculin was obtained twenty-six days after inoculation, although it appeared sixty-eight days after inoculation, and post-mortem examination seventy days after inoculation disclosed marked tuberculosis of the peritoneum, extending gradually to the pleura and the pericardium, and involvement also of a few of the lymphatic ganglia connected with the peritoneum. The fourth calf died twenty-six days after ingestion of tuberculous material, and only tuberculosis of the glands connected with the alimentary canal was found, with tubercle bacilli in the œsophageal glands. Thus, of four calves inoculated with human tubercle bacilli, tuberculosis developed in two that survived long enough for definite results to appear. Observations of a similiar character have previously been made by others, and there can be no question as to their significance. Taken in conjunction with existing evidence, it must be conceded that they prove conclusively the communicability of human tuberculosis to cattle.

MENTAL DISEASE AND ITS PROGRESSION.

NERVOUS affections are at once the outcome, and the bane of modern civilization. They are the tribute exacted from those who wilfully rebel against the laws of health, by continually living at too high pressure. The people of the present day, through heredity, and other causes, are, for the most part, not best fitted to withstand the excessive mental and physical strain to which so many subject themselves.

Nevertheless, by reason of inherited temperaments, few seem able to live placidly, but hurl themselves with ever-increasing vehemence into the maelstrom of business, dissipation, politics, and the rest.

Thus, while conditions adverse to the conservation of vital and mental force are always intensifying, the human product of latter-day civilization is at the same time more impelled to strive, and less capable of bearing the effort.

The modern man has evoked a Frankenstein which not infrequently devours him. In no country is this state of affairs so manifest as in the United States, and consequently nowhere are mental disturbances more common.

A proper conception of disorders of the nervous system, until recent years, has not been evinced by the neurologist.

Dr. Theodore H. Kellogg published in *The Journal of Nervous and Mental Diseases*, November, a paper entitled "The Stadia of Mental Disease," in which he demonstrates his views with regard to the course of progression pursued by mental maladies. He holds that such affections are essentially progressive, and that like most other diseases, have well-marked stages. For instance, almost all nervous affections plainly have incubatory, acute, and convalescent stages, and while mental diseases are often greatly prolonged, and have multiform symptoms, it is possible, by the careful study and comparison of very large numbers of cases to deduce the rule of the stadia, which form attacks of insanity tend to discover general uniformity in the order in which they occur.

Dr. Kellogg's main conclusions are in brief as follows: The vast majority of attacks of mental disease have but three simple stadia. The main stadium acutum is constituted chiefly of the maniacal, melancholic or stuporous states, which are mere symptoms—symptoms alternating or replacing one another, though sometimes mistaken for separate attacks of insanity.

Mental disease must be regarded as one continuous pathological process, with periodic fluctuations so constant that remissions and intermissions are to be viewed as part of the morbid phenomena.

The diversified varieties of insanity, and the artificial variety of its forms described by modern writers, may, in great measure, be reduced to clinical simplicity by the law of the stadia, conjoined with the maniacal, melancholic, and stuporous states, as here rightly assigned to the position of symptomatic syndromes rather than independent forms of alienation.

In fine and in fact, the law of stadium and rhythm and of the dominant states of expansion, depression, and stupor are the only stable data capable of any wide purpose for the logical unification of the multiform manifestations of mental disease.

It will be observed that the point in Dr. Kellogg's argument which he especially wishes to impress upon the minds of his readers is that mental disturbances proceed in progressive order, and that independent insanities in rapid succession do not occur.

Dr. Kellogg, referring to the stadia of strongly hereditary insanities, says: "The incubatory stadium progresses on predestined hereditary lines throughout childhood; the stadium acutum begins with the first decided mental disorder at the pubescent crisis, and covers the whole course of life. The apparent recoveries between the attacks are not real, but are only intermissions in the progressive malady which, if life is sufficiently prolonged, ends in a stadium dementiæ of the active kind peculiar to the degenerates."

An intelligent understanding of mental disease can only be arrived at by a close study and observation, and by long and varied experience. The advance in knowledge of nervous affections has been most marked within recent years, and the observations of Dr. Kellogg go to show that this rate of progress is being well maintained.

TREATMENT OF CONSUMPTION BY THE ADMINISTRATION OF UREA.

It has been proved to the satisfaction of a large number of persons that gout and genius are closely allied. For a considerable time, too, the fact has been noted that those possessing the so-called gouty diathesis are seldom the victims of tuberculosis. Gout, then, in addition to having a peculiar affinity with those of that abnormal brain development known as genius, would seem to confer a large degree of immunity to perhaps the most fatal disease from which the civilized race suffers.

Many physicians have, within recent years, drawn attention to this coincidence, Sir Herman Weber in particular.

Dr. Henry Harper, Nottingham, England, has, during the past year, contributed three articles to the *Lancet*, March 9, June 15, and December 7, 1901, in which he gives at length the results of experiments, and deductions therefrom, in regard to this matter. He contended that if the gouty diathesis renders a person immune, or partly immune to tuberculosis, that the administration of urea, or uric acid, might have a favorable influence upon the disease itself. For reasons which are described at length, urea was chosen as the experimental agent, and after a trial of two years and a half Dr. Harper declares that in certain forms of tuberculosis this treatment has met with great success.

Indeed, he goes so far as to assert that urea exerts a specific action on tuberculosis quite as marked as mercury on syphilitic node, salicylate of soda on a painful joint in rheumatic fever, or iodide of potassium on bronchial asthma.

The cases which Dr. Harper considers suitable for the administration of urea are: (1) Circumscribed pulmonary tuberculosis of the lung in which the sputum exhibits abundance of bacilli and only a limited number of cocci, (2) Enlarged tuberculous glands situated on any part of the body, (3) Tuberculous pleurisy, (4) Tuberculous laryngitis, (5) Lupus; (6) Tuberculosis of peritoneum with fluid in the peritoneal cavity, (7) Hydrocephalus in children, and (8) Tabes mesenterica or carreau. Cases which are unsuitable are: (1) Pulmonary tuberculosis where cocci predominate; (2) Acute miliary tuberculosis with a high temperature (103° F. or over); (3) Gastritis, (4) The last stage of tuberculosis where the patient is dying, and (5) When the patient has a temperature over 101° F.

Mode of administration, beginning with small doses, 10 to 15 grains thrice daily, gradually increasing up to 40, 50, or 60 grains as a maximum.

The best and most obviously apparent good results have been gained from the use of urea in diseases like lupus and superficial tuberculous glands.

Mr. Arthur H. Buck of Brighton in the *London Practitioner*, July, strongly corroborates Dr. Harper as to the value of urea in the treatment of tuberculosis, and gives an account in that journal of a remarkable cure of a case of lupus vulgaris by the administration of urea.

Dr. Harper holds the view that the less animal food ingested, the greater the number of tuberculous cases, and vice versa, and lays down the dictum that "nitrogen and nitrogenous products are the remedy par excellence of the tubercle bacilli."

Our knowledge of tuberculosis and its treatment is constantly growing, and it is possible that Dr. Harper's favorable experience with urea may impel others to experiment along the same lines, and to prove its value and its limits.

The Supply Table of the army medical department, which was revised in 1899-1900, is now undergoing a second revision by a board of medical officers, with a view of correcting any deficiencies and inaccuracies developed by practical experience in the field with respect to the supply table of 1990. Comparisons made on the spot of the equipment of the medical departments of the various foreign armies lately operating in China showed the great superiority of the equipment supplied in the United States service, and Surgeon-General Sternberg is making every effort to maintain this superiority and bring even closer to perfection an equipment already of a very high character.

The General Medical Council of Great Britain.

It is curious to observe into what ill-odor the General Medical Council of Great Britain seems to have fallen. The references made to it in the correspondence of British medical writers to American journals display a scarcely veiled contempt for its proceedings, and on occasions are indicative of a distinctly harsh and critical attitude toward its composition and all connected with it.

There must, then, be "something rotten in the State of Denmark," or there would hardly be so surprising a unanimity of opinion with regard to the seeming lack of usefulness presented by this ruling body of English medical men.

Perhaps the special correspondent to the Medical Record hits the right nail on the head when, in his letter of November 22, he remarks "so little is hoped for from the council, with its solid phalanx of corporation interests."

Mr. Victor Horsley, ever since his election, has been a thorn in the flesh to the reactionary or unprogressive members of the council, and will probably continue to vex their souls with his radical views. It might be to the advantage of the British medical profession at large if more new blood were brought into the council, and if many of its time-honored traditions were upset once and for all. The fight of the coming session will wage fiercely around the midwives' question, To register or not to register

Relative Ranks in Medical Departments of Army and Navy.

The reappointment of Surgeon-General Van Reypen, of the Navy, to serve in his present position until his statutory retirement for age in the coming spring, calls attention to the inequality of the emoluments and reward for service in the several medical departments of the Government. Surgeon-General Van Reypen, under the existing law, will retire with the rank and pay of rear-admiral—equal to that of a major-general of the army—while Surgeon-General Sternberg, who retires for age at about the same time, must content himself with the emoluments of his present rank of brigadier-general. Without contrasting the relative magnitude of the worth and responsibilities attached to the offices of the medical heads of the army and navy, it would seem that while the naval branch has certainly not received too much at the hands of Congress, the rewards in the military branch are not commensurate with the distinguished services rendered the profession and country.

Incidents in the Career of the Late Sir William MacCormac.

Perhaps the most stirring part of the late Sir William MacCormac's active and varied life was the time he spent as a surgeon with the French troops during the Franco-Prussian War.

When he first joined the Anglo-American Ambulance, a body consisting of sixteen medical men, of whom eight were English and eight Americans, it was under the control of Dr. Marion Sims. On the reconstruction of this body, according to a writer in the *Lancet*, December 5, MacCormac was placed second in command, which position he shortly afterward, on the return of Dr. Marion Sims to New York, changed for that of surgeon-in-chief.

Each day considerably more than one hundred major operations were performed, and MacCormac's share of these was more than would have fallen to him by lot. A day of his work at Caserne d'Aspeld cannot be better described than in his own words: "I did not succeed in keeping a record of all the work that was done that day. Indeed, I only wonder I kept any record at all. I find, however, that I performed several amputations of the leg, the thigh, the forearm, and the arm; that I excised the shoulder and the elbow-joints, and also performed partial resections of the upper and the lower maxilla, and of nearly the whole ulna. The number of bullets and pieces of shell that were extracted are too numerous to mention."

Sir William MacCormac's literary output was by no means large. The most popular, perhaps, is: "Work under the Red Cross," an illustrated diary of his experiences during the Franco-Prussian war.

It is undoubted, says the aforementioned contributor to the *Lancet*, that Sir William MacCormac's sudden death was mainly due to the arduous work performed by him in the South African War. He contracted dysentery in South Africa, which so undermined his constitution that he never recovered his wonted vitality. He was to a great extent a martyr to duty and science.

Purchase of Medical Supplies for the Army.

The medical department of the army is endeavoring to secure the reënactment by Congress of an old law, which permitted the purchase of medical supplies without the usual formality of advertising for competitive bids in each instance. Because of the peculiar nature of these supplies, it is scarcely practicable to fix a standard upon which intelligent competition can be based. There is, for instance, no established standard for many drugs and chemicals, and different bids for articles of the same name may be for articles of widely different quality, variety and usefulness—price thus becoming the factor least worthy of governing the choice. There are also certain kinds of service, such as laundry work in hospitals, which cannot very well be let out to the highest bidder. Army red tape in this instance certainly stands in the way of an efficient administration, and it is to be hoped that Congress may appreciate the fact and place this matter on a sound business basis.

The Over-supply of Ministers and Physicians.

The medical man is apt in these days to bewail his hard lot in having to contend with competition both from without and within, and to declare that it becomes daily more difficult to make a decent living at the practice of his profession. The path of the ordinary medical practitioner is, indeed, not strewn with roses; but, as was pointed out in the Medical Record about a year ago, the minister has, in many respects, a rougher road to travel than his medical brother.

The relative earnings of the two professions were then shown to exhibit a decided advantage in favor of the doctor.

Neither of these callings, however, is perhaps paid in proportion to the merits of its followers, or to the expenditure of money and brains requisite to become qualified.

The cost of gaining an entrance to the medical profession is, on the whole, considerably greater than of being admitted to the ministry, and, therefore, it would seem but fitting that the doctor's opportunities of making money should be wider than those of the preacher.

In both instances the reasons for the meager returns are the same, over-supply and consequent bitter competition.

"A Pastor," writing recently to the Chicago *Interior*, decries in strong terms the tendency of the age to the young men to enter the church, and goes on to say that the apparently inexhaustible supply of young ministers has operated to create a general belief of [illegible] among our churches, so that there is not greater [illegible] and [illegible] profession, but [illegible] of an [illegible] character, in which a competent and [illegible] man holds his position with as much uncertainty as does a pastor.

"We should," remarks the writer, "be wisely [illegible] to acknowledge that we have trained a larger number of ministers than can be respectably supported, and we should cut off the aid now so indiscriminately offered to young men, excepting those who may be willing to go to the foreign field."

If Proctor's facts are true, we agree with him that it is by no means in the best interests of religion that the cost of the training for the church of an altogether superfluous number of young men should be defrayed by charity. The remedy for over-supply in both the medical and clerical profession would be to make the test of admission much more severe than it is at present.

Sickness in the Philippines

The report of the Philippine Commission recently made public deals largely with matters relating to the public health. Consumption is stated to be the greatest cause of mortality among the natives in Manila, and the Commission says that "measures are now being taken to ascertain the exact whereabouts of all persons in Manila suffering with this disease with a view to the possible establishment of a consumption colony outside the city limits for those cases where danger of infecting others is greatest." While the number of lepers in the Philippines has been estimated at as high as 30,000, the Commission is rather inclined to the belief that there are actually less than a third of this number of cases of leprosy. "A leper census of the islands is being taken with a view to the eventual segregation of all persons suffering with this disease on the isolated but fertile and healthful island of Cagayan, where they can be given better care, allowed greater liberty, and made more contented, than when confined in hospitals." The constant presence of bubonic plague in Manila and the adjacent towns, together with the prevalence of smallpox among the natives in a number of provinces, causes the Commission to say that the board having charge of the health interests of the islands has plenty of work to do. For its assistance in the study and diagnosis of disease the Commission recommends the establishment by the Government of a number of laboratories. The Commission combats the statement made generally in the press that a large number of soldiers serving in the islands have been made insane by climatic conditions, and says that "the truth is that the large majority of cases of insanity among the soldiers have been produced by drinking so-called 'vino,' which has been shown by chemical analysis to contain in some instances as high as 17 per cent. of fusel-oil, and is therefore a deadly poison." Rinderpest is stated to prevail extensively among the cattle of the island.

Explosion in a Utica Hospital.—By the explosion of a water sterilizer, the Fox Hayward surgery in Faxton Hospital, Utica, N. Y., was wrecked on Thursday night of last week. No one was in the room at the time. The damage amounts to about $1,500. The explosion awakened the patients and medical attendants in the institution and caused much alarm until the nature of the accident was ascertained.

News of the Week.

The Quarantine Against Mexican Gulf Ports, established in the spring, has been raised by the Texas State Board of Health and the Marine Hospital Service, these ports being officially declared entirely free of yellow fever.

An Old Primipara.—A woman sixty-five years old, gave birth last week, in a New Jersey town, to a healthy girl. The woman's husband is seventy years old, though both are said to be young looking for their years, and the couple had passed forty years in a childless wedlock.

Smallpox.—Compulsory Vaccination has been decreed in Boston by the Board of Health, an order having been recently issued that all the inhabitants of the city who have not been successfully vaccinated since January 1, 1897, be vaccinated or revaccinated forthwith. There is some question as to the legal right of the board to enforce such an order, which is unqualified in its construction, but it is believed that the board will be backed up in its new position by public opinion, and that no efforts will be spared to carry the order into effect. Since January 1, 1901, there have been 400,000 vaccinations in the city. In Philadelphia the energies of the Health Department are directed to disinfection, 150 formaldehyde generators being in constant use. Not only the infected buildings but those adjoining them are regularly disinfected, and the authorities will also disinfect every building, whether public, parochial, or private, which is used for school purposes. There has been a marked falling off in the number of new cases in that city during the past two or three weeks. Five cases of smallpox were found in one house in Jersey City last Saturday, one of the patients being moribund when the health authorities made their discovery. The father was a disbeliever in medical science, and had called in no physician although his wife and four children were taken down with the disease one after the other. After the sick had been removed to the smallpox hospital the father himself came down with the same disease. Five other cases have been found in the same neighborhood, all doubtless originating through intercourse with the children of this family.

Sickness Is Very Rife in London, and this fact, in conjunction with the gloom imparted by the Boer war, has caused a feeling of pessimism among all classes. The fever returns of the capital of England have been of late very disquieting. It is stated that there were on November 30, 4,985 patients in the several fever hospitals of the board, 3,203 being cases of scarlet fever, 1,521 of diphtheria, and 249 of enteric fever.

The Army Medical Department will not be represented at the Exposition at Charleston, but is already preparing estimates as to the funds and space required for a large indoor and outside exhibit at the St. Louis Exposition in 1903.

Private Julius Heinze, Hospital Corps, U. S. Army, has recently been recommended for a medal of honor as a reward for heroism at the battle of Gandara River, Island of Samar. Heinze fought as long as he was able while shot through both arms and with a bad bolo wound in the back. After recovering from a fainting spell, with both arms in slings, he directed the work of transporting the other wounded until they arrived safely at Calbayoga. The medical officer present recommended Heinze for a certificate of merit, but the commanding general regarded the man's heroism as worthy of the higher award of a medal of honor. This is not the first time that Private Heinze's bravery has won high praise from his superiors, for in the campaign in China, in which he participated, he was recommended for a certificate of merit for distinguished bravery at the battle of Tientsin.

The Marine Hospital Service.—A bill has been introduced into Congress by Mr. Hepburn calling for many changes in this service. It is proposed to alter the name to the United States Health Service, in order to bring the title more into harmony with the work which the evoluted service is now doing. The officers of the new service will be the same as of the old, except that those in charge of the administrative departments in Washington will be called assistant surgeons-general, and the pay of the surgeon-general will be increased to equal that of the surgeon-general of the army. A consulting board is to be created to advise the surgeon-general of the new service in matters relating to public health, and this officer will also consult with delegates from the health departments of the various States and Territories of the Union. Uniformity in the registration of vital statistics is provided for by the bill. It will be the duty of the surgeon-general of the new service to prepare proper forms for collecting the data, in conjunction with the State boards of health, and to compile and publish them as a part of the reports of the service. The consulting board above mentioned will consist of the Surgeons-General of the Army and the Navy, the Chief of the Bureau of Animal Industry in the Agricultural Department, and the Director of the Laboratory in that bureau, and five other members not regularly in government employ. The service will remain a bureau of the Treasury Department, and the Secretary of the Treasury is instructed to prepare rules for the service and to prescribe uniforms for its officers and employees. His annual report will contain a detailed account of the work performed by the health service.

Food Allowance for the Insane.—The State Commission in Lunacy has established a new ration allowance for patients in the State hospitals, which is being made the subject of much sharp criticism. Among the changes it has cut out potatoes from the dietary, substituting therefor certain cereals which a learned comparison of chemical constitutions and calories has demonstrated to be of equal nutritive value. It has also stopped the use of butter at dinner. The managers of the Hudson River State Hospital have sent a formal protest to the commission against the new ration.

Dr. Gordon G. Burdick has been elected a member of the faculty of the Illinois School of Electro-Therapeutics of Chicago.

A Tuberculosis Ordinance in St. Louis.—A bill has been introduced into the City Council of St. Louis making obligatory the reporting to the health authorities of all cases of undoubted pulmonary tuberculosis. Examination of the sputum for diagnostic purposes will be made, on request of the attending physician, by the Board of Health officials. After notification of a case of consumption, the Health Commissioner is ordered to give, through the physician in charge, such printed instructions in relation to the management of the sanitary features and surroundings of the case as will insure the best means of preventing a spread of the disease. The apartments occupied by a consumptive are to be regularly cleaned and disinfected, but it is forbidden to placard any house in which a case of the disease exists. The penalty for not reporting a case of pulmonary tuberculosis is a fine of not less than $50 nor more than $250. This bill was prepared to obviate certain objectionable features in a bill of similar import, which was recently defeated in the council.

Advisory Board of the Pathological Institute.—The Lunacy Commission recently appointed an advisory board for the Pathological Institute of the New York State Hospitals, with whom Dr. Meyer, the new Director, is expected to confer from time to time regarding the scheme of investigation and research. This board consists of Drs. Cattell, Department of Psychology, Columbia University; Ewing, Department of Pathology, Cornell University; Herter, Department of Pathological Chemistry, University and Bellevue Medical College; Bumpus, Department of Biology, American Museum of Natural History; Hun, Department of Nervous Diseases, Albany Medical College; C. W. Pilgrim, Superintendent Hudson River State Hospital for the Insane, Poughkeepsie; A. E. Macdonald, Superintendent Manhattan State Hospital for the Insane, Ward's Island, and Frederick Peterson, President of the Lunacy Commission, *ex officio*.

Metropolitan Medical Society of New York.—At the last meeting in 1901 of this society, the following officers were elected for the ensuing year: *President*, Dr. W. M. Leszynsky; *Vice-President*, Dr. F. L. Wachenheim; *Recording Secretary*, Dr. W. M. Brickner; *Corresponding Secretary*, Dr. S. Yankauer; *Treasurer*, Dr. I. Pierce Oberndorfer.

Philadelphia Neurological Society.—At a stated meeting held [December 23, Dr. D. J. McCarthy gave a "Demonstration of the Absence of the Supraorbital Reflex After Removal of the Gasserian Ganglion." He described this reflex, which consists in fibrillary contraction of the lower fibers of the orbicularis palpebrarum on irritation in the distribution of the supraorbital nerve, and he exhibited two cases, one of removal of the Gasserian ganglion and another in which the sensory division of the fifth nerve had been divided, in both of which this reflex was absent. There thus seems good reason for believing the manifestation a true reflex whose arc is comprised in the supraorbital division of the fifth nerve, the medulla oblongata, and the seventh nerve. Dr. G. Betton Massey read a paper entitled "Static Electricity in the Diagnosis and Treatment of Hysteroidal Disorders." He pointed out the marked tolerance by such patients of current-strengths that cannot be borne by ordinary patients, and he considered this merely as a manifestation of the general state of hypalgesia. Dr. John K. Mitchell made some remarks upon "The Treatment of Locomotor Ataxia," referring especially to the useful influence upon the motor manifestations of rest and massage, of deep pressure and of the application of a flannel bandage in the treatment of the lancinating pains, of lavage in the relief of gastric crises, and of the rapidly interrupted faradic current in that of the rectal crises. Dr. William G. Spiller read a paper entitled "The Area of Anæsthesia Caused by Destruction of the Spinal Cord in a Case of Fracture of the Tenth Thoracic Vertebra, with Exhibition of the Specimen." In this case the knee-jerks were absent, and there was anæsthesia as high as the level of the umbilicus. On post-mortem examination not only was the cord found crushed in the situation of the injury to the vertebra, but there was also inflammation below. Dr. Alfred Gordon read a paper entitled "Remarks on Verbal Amnesia Apropos of a Case of Sensory Aphasia." The patient was a woman with valvular lesions of the heart who, following an apoplectic seizure, presented right hemiparesis, with defect of speech consisting principally in inability to recall the desired word. She heard, saw, and comprehended perfectly, but she exhibited difficulty in reading and in meeting. Drs. C. P. Van Epps and D. J. McCarthy read a paper entitled "Gelatinous Exudates in the Cerebral Ventricles," showing a specimen from an insane patient in which a gelatin mass was contained in one of the ventricles.

The Section on Laryngology and Rhinology.—At a meeting of the section of the New York Academy of Medicine held December 18, 1901, Dr. Emil Mayer was elected Chairman and Dr. Z. L. Leonard, Secretary.

Prize for an Essay on the Effects of Morphine.—Dr. J. B. Mattison of Brooklyn has offered a prize of $400 for the best paper on the subject, "Does the Habitual Subcutaneous Use of Morphine Cause Organic Disease? If so, What?" The contest will be open for two years from December 1, 1901, to any physician in any country. The award will be determined by a committee consisting of Dr. T. D. Crothers, Hartford, Conn., editor *Journal of Inebriety*, Chairman; Dr. J. M. Van Cott, Professor of Pathology, Long Island College Hospital, Brooklyn, and Dr. Wharton Sinkler, Neurologist to the State Asylum for the Chronic Insane, Philadelphia. All papers must be in the hands of the Chairman by or before December 1, 1903. They will become the property of the American Association for the Study and Cure of Inebriety, and to be published in such journals as the committee may select.

Memorial Tablet to a Physician.—A tablet to the memory of Dr. Charles Meigs Wilson was unveiled at the Philadelphia Lying-in Charity and Nurses' Training School on December 28. The memorial was erected by fourteen nurses who had been pupils of Dr. Wilson when he was physician to the school. Dr. Wilson was graduated from Jefferson Medical College in 1884 and died in 1891. He was the founder of the Nurses' School, and was chiefly instrumental in having the present hospital building erected.

Generous Bequests.—By the will of the late George W. Farr, Jr., of Philadelphia, residuary bequests are made as follows: Rush Hospital for Consumptives, $5,000; Pennsylvania Hospital, $10,000, the income of which is to be used toward ameliorating the condition of the insane poor by establishing two free beds, one in memory of the testator's father, John C. Farr, and the other in memory of his mother, Clementine A. Farr; Wills Eye and Ear Hospital, $5,000 in memory of his father; Philadelphia Home for Incurables, $5,000, for a free bed in memory of his sister, Emma S. Farr; Polyclinic Hospital, $2,000.

Obituary Notes.—Dr. JAMES M. WALLIS died at Philadelphia on Dec. 28, seventy-seven years old. He received his academic education at Dickinson College and his professional training at the University of Pennsylvania, graduating from the medical department of the latter institution in 1847. On the outbreak of the Civil War he entered the Federal Army and was assigned to duty at Mower General Hospital at Chestnut Hill. He subsequently became Post-Surgeon at Baldwin, Fla., with the Olustee expedition. At a later period of the war Dr. Wallis was in medical charge of Battery Gregg, and of Fort Wagner, opposite Charleston, S. C., of the Post Hospital at Jacksonville, Fla., of the Annapolis General Hospital, of the hospital at Horn Point, Md., and of the Satterlee General Hospital in West Philadelphia. At the close of the war he resumed the practice of medicine in Philadelphia, retiring, however, some twenty years ago. He is survived by two sons, Dr. J. Edward Wallis and Dr. J. Frank Wallis, and by two daughters, one of whom is the wife of Dr. J. F. Roderer.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

GENERAL MEDICAL COUNCIL ELECTIONS—SMALLPOX—THE RELATION OF LYMPHADENOMA TO TUBERCULOSIS—CANCER SUPERSTITIONS—[illegible]—PRINCE'S APPOINTMENTS—OBITUARY NOTES.

London, December [illegible], 1901.

The election to the General Medical Council has resulted in the return of Mr. George Brown for another period of five years, and Mr. George Jackson of Plymouth, who is a new member. Both are general practitioners and ran together. Mr. Victor Horsley opposed them with all his power in the hope of securing Dr. Woodcock, who only received 3,161 votes, while Mr. Brown had 5,369 and Mr. Jackson 6,518. It should be a lesson for Mr. Horsley, who will have to face an election next year, and has given much offence by his electioneering, and certainly has compromised his dignity by throwing about imputations of untruthfulness. Not half the voters returned their papers. With so many abstentions, it would seem that the constituency expects little from the council.

Dr. Bruce has been re-elected for Scotland.

Smallpox steadily increases—the fifth hundred, under treatment, has been passed.

The Pathological Society's debate on lymphadenoma and its relation to tuberculosis was opened by Mr. Butlin, who referred to the confusion which exists as to nomenclature, one surgeon designating a case lymphoma, another calling it lymphosarcoma, and a third lymphadenoma. Others depended on examination of the blood for diagnosis. Contrary to the common statement, Mr. Butlin denied that there is any hypertrophy of lymphoid tissue, but held that the disease presents as definite a structure under the microscope as epithelioma.

As to its relation to tubercle, he said, it is not tuberculous infection of a gland, but it does not exclude tubercle; nor does it give immunity, and he was not sure that it may not render the patient even more susceptible to tuberculous infection. Dr. F. W. Andrewes discussed the histological and bacteriological aspects of the question at length, and summarized his views in the following conclusions: (1) Lymphadenoma is a distinct and separable disease, histologically recognizable, and is not due to the tubercle bacillus. (2) There exists a form of tuberculosis of the lymphatic glands clinically indistinguishable, but recognizable histologically and bacteriologically; (3) Secondary infection with tubercle is not rare in lymphadenoma, and such infection may be local and trivial, or may gain the upper hand, the patient dying from generalized tuberculosis, with a puzzling mixture of lesions, whence has arisen the erroneous belief that lymphadenoma is only a form of tubercle.

Dr. Lee Dickenson related a case in which tubercle supervened on a case of lymphadenoma.

Professor MacFadyean had not met with lymphadenoma in animals, and doubted if a genuine case had ever been seen. Growths occurred in the spleen of the horse, which certainly were not tuberculous, nor had they the structure of the specimens exhibited by Dr. Andrewes. In tuberculosis the glands first affected were not the same as in lymphadenoma.

Dr. Newton Pitt doubted the possibility of distinguishing a tuberculous from a lymphadenomatous gland. Out of 7,000 necropsies, eighteen had been regarded as lymphadenoma, but three of these were found to be tuberculous, although during life they were not considered so. In three other cases there was caseation, but he thought that in them tubercle had been superadded. He suggested the use of tuberculin as a diagnostic. It had been said that lymphadenoma might be a para-tuberculous process, as tabes is a para-syphilitic process, but he did not think it could be, and mentioned a case of death within nineteen days from lymphadenoma affecting gland, spleen, and liver, without a trace of tubercle. He referred also to another case which ran a rapid course to the fatal end.

Cancer is a subject of perennial interest to the public, and every little while some new cure or preventive is announced in the newspapers. Lately we have had rather a surfeit of this sort of writing, and some papers have been busy with the cause of the disease. As you may suppose, most of the communications indorsed by sensational newspapers are merely revivals of old, long exploded notions, and those which have anything new about them are as absurd as their predecessors. Leaving them to their ephemeral notoriety, I may mention some professional contributions to the subject which have just been made.

Foremost perhaps should be that of Mr. T. Bryant of Guy's, who lately wrote to the Southwest London Medical Society an account of some cases treated at the Bolingbroke Hospital by the *x*-rays. He said that not only in lupus is the beneficial effect such as is generally known, but that he had had good success in rodent and epithelial ulcers of the skin, and in one typical epithelial tumor of the lip, which did not seem suitable for operation. This patient was shown to the society. Further, a private patient on whom he operated a year ago for cancer of the breast, and in whom recurrence took place in August last, was so much benefited by the rays that she was willing to be shown at the meeting. Pain ceased about a fortnight after the treatment began, and now, three months afterward, the report is that many active tubercles have entirely disappeared, and all others are disappearing. An ulcerated nodule, the size of a crown, upon which there was a scab, has healed under the scab, and flattened out; the nodule next to it has assumed a like shape, and is far less prominent. The skin which was fixed has become movable. A tubercle on the scar in the axilla is withering. In a second case, recurrent cancer, now in hospital, similar changes are going on. Mr. Bryant emphasized that the treatment is painless, and gives reason for hope, but that we must not yet talk of cancer cures, though we seem justified in saying the *x*-rays will kill pain and retard growth. How much more they may do has to be worked out. The treatment of all the *x*-ray cases at the hospital was carried out by Mr. C. R. C. Lyster, Medical Superintendent, and his assistant, Mr. E. M. Perkins, and these gentlemen expressed their readiness to demonstrate their methods and appliances to any member of the society.

Other gentlemen have observed cases improve after the *x*-rays, but the position of Mr. Lyster leads me to give prominence to his statement, and it is not necessary to say that he knows well enough that tumors apparently cancerous have disappeared after different remedies—or none at all. I indorse then his statement that we must not yet talk of cures.

Some years ago, a very eminent clinical teacher told me confidentially that he had had several successive cases apparently cured, and felt inclined to believe he had really hit on a cure, which was, if I remember rightly, a form of chalybeate. The cases he was successful in were uterine.

Now, here is Dr. Robert Bell of Glasgow saying he cures such with thyroid preparations. Long ago, you will remember, how another gynecologist assured us we might repose our faith in Chian turpentine. I might mention other instances which have been so disappointing that when I hear of such cures I "listen and perpend." But before turning from the subject of cancer, I must mention a notion as to its cause. No, not the innocent tomato which has been blamed by newspaper quidnuncs, but something more universally ingested. Nothing less than salt. This notion is propounded by Dr. James Braithwaite, the editor of the *Retrospect*, which is issued half-yearly under this name, and has been for two generations. He is also obstetric physician to the Leeds Infirmary and lecturer on gynecology in the Yorkshire College. The paper in which he put forth that excess of salt in the diet is a probable factor in the causation of cancer was read at the Leeds Medical Society, and has been accorded a place in the *Lancet*.

He does not assert that he has proved his point. He admits "the theory is more a suggestion than anything else—merely a new idea for consideration." Not a theory at all, then, at the utmost, therefore a—guess, or shall I say—hypothesis?

The idea has the merit of not being dangerous, as it would not interfere with other treatment to restrict the use of salt in the diet, though it would not be easy to exclude it altogether.

But what a shock this idea must give to Mr. Godfrey Gümpel, who wrote a five-shilling volume in 1898, entitled "common salt," to prove it to be essential to health and a cure for most diseases, and since then has published pamphlets on cholera and plague to show they are amenable to salt, and this year another on epidemic diseases in India and the Tropics, in which he lashes impartially the Indian Government and the medical profession for their neglect of his sovereign remedy—salt.

The Prince of Wales, Junior, as he is reported to have called himself, has made the medical appointments to his household, which correspond pretty nearly with those to the King's.

The funeral of the late Sir Wm. MacCormac took place on Monday. The king was represented, as were also the French and German embassies, the royal colleges, St. Thomas's hospital staff, the army and navy departments, and many other institutions.

Surgeon-General Harvey, C.B., D.S.O., etc., who died on the 1st inst., was a very distinguished officer. He entered the army in 1864, and soon after went into the Indian medical service, in which post after post has been conferred upon him, up to the director-generalship and sanitary commissionership of the Indian Government He was the son of Professor Harvey of Aberdeen, where he graduated in 1863, being then twenty-one years old.

Another nonogenarian has finished his course, Dr. J. W. Edger, who was reported to be the oldest doctor in the country, ninety-eight. He practised a long time at Kirkby Stephen. He had three brothers, all doctors, who died at the respective ages of ninety-four, ninety-three, and eighty.

Sir Charles Nicholson, Bart., M.D., J.P., etc., the eminent Australian, is still with us, having come back to the old country to retire. He has entered his ninety-third year, and is in good health.

The deaths are announced of Dr. W. Dobie, J.P., of Keighley, where for many years he held a most influential position. He was sixty-five years old.—Alderman J. D. Harries, consulting surgeon to the Salop Infirmary, and for above forty years surgeon to the county jail, aged sixty-six.—Dr. Campbell Clark, Superintendent of the Lanark Lunatic Asylum, whose "Manual of Mental Diseases" was published in 1897, you may know. He graduated with honors at Edinburgh in 1866.—Deputy Inspector-General Piers who entered the naval medical service in 1846, and was on the expeditions in search of Franklin, which discovered the Northwest Passage. He held the Arctic Medal. He died on the 30th ult., aged eighty-four.

OUR PARIS LETTER.

(From Our Special Correspondent.)

MEDICAL PLAYS PRODUCED IN FRANCE—EFFICACY OF MEASURES USED AGAINST CONSUMPTION—OXYDE OF CARBON IN THE BLOOD OF ANIMALS LIVING IN PARIS—SEROTHERAPY OF TYPHOID FEVER BY CHANTEMESSE—THE SANITARY CONDITION OF CANNES—THE WINE LAWS IN FRANCE—DR. DEBOVE NAMED DEAN OF THE FACULTY.

PARIS, December 13, 1901.

THEATRICAL works that have to do with medical subjects are getting to be more and more frequently produced in France. A play recently brought out, called the "Baillon," destined to show the disastrous effects of professional secrecy in cases of contagious disease. A woman, a consumptive, has one lover who jilts her because he finds that she is a consumptive. She gets married later on, but is separated from her husband and kept away from children, and finds out at last that it is because she is suffering from tuberculosis. Another play, called "Les Avaire's," which means the damaged ones, deals with the disastrous results of syphilis in a family. A young man consults a doctor who warns him that he must not get married. A year or two later the doctor is called in to see an infant suffering from hereditary syphilis, and discovers that the father is the young man he had already seen. The nurse must be discharged, but the mother-in-law and son try to bribe her without letting her know what the child is suffering from; she is informed of the nature of the disease by a servant who had been eaves-dropping and breaks out into reproaches, which are overheard by the wife, who happens into the room just at that moment. This play was forbidden by what is called the "censure," but was read before a select audience at the theater Antoine. The play was much appreciated, and some critics felt that it was hardly just to forbid the production of a play which would have so educational a tendency. Brieux, who is the author of the play, is a member of the Ligue against syphilis.

The tuberculosis commission established recently had asked the railway companies to place spittoons in the stations. Statistics have been made to see how much these spittoons were used, and it has been found that a great many people expectorated on the floor. Out of forty-three persons who had expectorated only six had used the spittoons. One can see by this how long it will be before the public will learn the elementary principles of hygiene. According to a report presented to the Society of Biology by Dr. Nicloux, oxyde of carbon is always found in the blood of animals living in Paris. Dogs that had been kept in the open fields twenty-four kilometers from the city were found to have their blood impregnated to some slight extent by oxyde of carbon. The quantity of this gas doubled and even tripled after a sojourn of twelve days in Paris.

Professor Chantemesse chose as the subject of his first lecture at the School of Medicine the serotherapy of typhoid fever. Dr. Chantemesse had already described at the congress of Madrid in 1898 the method he used in preparing the toxin of typhoid fever, and in obtaining a serum. He has been trying it recently on a number of patients in his service as well as in those of his colleagues. A hundred cases were experimented on and they will [illegible] their place. These [illegible] would seem to be much more favorable than those situated at the same time [illegible] treatment, the mortality [illegible] as high as [illegible] per cent. A [illegible] in the temperature is noted after the [illegible] of preventing it [illegible] The fall in the temperature is not the only result of the [illegible] being also a large increase in the quantity of urine [illegible] The dose [illegible] The [illegible] of the [illegible] is a [illegible]

Last April an epidemic [illegible] at Cannes and it was thought at the time that the disease was typhoid fever. Articles were published in the foreign newspapers concerning this epidemic, and the tourist population of the coast was affected. Dr. [illegible] a physician of the place, has written an article in the Presse Médicale, in which he seeks to prove that [illegible] and especially in its abdominal form. He bases his statement on the [illegible] of the disease, the [illegible] the frequency of relapses and the absence of intestinal symptoms. He [illegible] with good results.

The recent laws on the reduction of taxes in France have tended to make wine cheaper, so that in certain parts of France a bottle of wine can be bought for a cent. It was thought that if alcohol became cheaper there would not be such a large quantity of spirits drunk. Statistics have not shown this to be the case so far.

Professor Brouardel, the dean of the Faculty, handed in his resignation recently after fifteen years' service, and Professor Debove has been named in his place. Dr. Debove had at first refused to be a candidate because a certain number of the young professors [illegible] on certain details of his administration. He was able, however, to have his [illegible] carried out and was elected by a large majority.

THE NEW YORK ACADEMY OF MEDICINE, THE DUE QUESTION AND THE REAL DISTINCTION OF MEMBERSHIP.

To the Editor of the Medical Record.

Sir: It is unfortunate that the last meeting of the New York Academy of Medicine, which was notable for an unusually large attendance, should have been marred by certain proceedings which were, to say the least, in very bad taste. The presentation of letters of resignation and the dropping of members in arrears of dues afforded an opportunity for certain playful allusions by members of the Council. If there had been nothing but humor, there would have been no reason to trespass upon your space, for it would have served as a good setting for the excellent intellectual [illegible] treat which followed, but there was a [illegible] which seems to call for criticism.

When one member gave as his reason for his resignation that practically the same privileges were extended to outsiders as the members of the Academy, one of the trustees felt called upon to reply quite sharply to this simple candid statement of a well-known fact. Certainly no one will deny that, aside from receiving the programmes and having a little more liberty in the use of the library, a member of the Academy has no privileges which may not be enjoyed by a non-member. It is true that one who is not a member is deprived of the honor that goes with the membership, but in these days when the medical profession is [illegible] I suspect that there are not a few who ask themselves in the privacy of their homes whether the honor of being a member of the Academy is a satisfactory equivalent for the twenty dollars a year paid in dues. We hear very little of this in public because many are not so outspoken in their opinions as the writer of that letter of resignation, and as they do not feel that it is a heinous offense to hold different views from the Council of the Academy, they shrink from the unpleasant publicity that the expression of their heterodox notions might entail. Let us then commune together in the [illegible] of the Record family, and speak frankly and fairly. If the majority feel that they receive the just equivalent for their money, and that the present regulations regarding membership are what they should be, then let the minority accept the verdict. On the other hand, if there is any widespread dissatisfaction it is for the best interests of the Academy and of all concerned that it be made known. It seems to the writer not unduly mercenary for the members to insist that a substantial distinction should be made between the privileges of members and non-members. What would be thought of the Union League Club for example if it should announce to those eligible to membership that they were entitled to the same privileges as the members [illegible] for them to become members and so contribute to the support of the club. It is probable that such a proposition would be [illegible] regarded as absurd [illegible] and yet if the [illegible] of the Council of the Academy [illegible] to think, it would certainly be [illegible] recognized and appreciated by [illegible] the medical [illegible]

Let me make another suggestion and I am done. It is that the [illegible] of the Academy be [illegible] We all know that the proper conduct of a society demands of all officers at times the performance of such [illegible] duties as the [illegible] of the [illegible] and the dropping of [illegible] but I [illegible] be the last to object to the enforcement of strict [illegible] in this connection, yet these [illegible] are manifestly out of place in a public meeting. It was bad enough that such proceedings as I have described should have taken place at any public meeting of the Academy, but how [illegible] good taste and how [illegible] the invited guests must have been the [illegible] and the [illegible] those who [illegible] they had not been [illegible]

A M[illegible]

Progress of Medical Science.

Boston Medical and Surgical Journal, December 26, 1901.

A Plea for Pain and Patient.—Edward R. [illegible] asks what one would think of a man who would throw a bucket of water on the obliging individual who warned him that his house was on fire. Yet all physicians do that very thing when in the event of pain they [illegible] the individual uttering the cry, the warning. Opiates, bromides, chloral, etc., never did and never can reach the part in the seat of pain, except through the healthy tissues of the well man, and they never reach the special afflicted nerves until they have dulled the general sensory nerves. The first thing to do is to make a correct diagnosis of the ailment before the disease has been masked by symptoms due to drugs.

Congenital Elevation of the Shoulder.—Joel E. Goldthwaite reports two cases illustrative of the two types of the deformity. In one the position was probably due entirely to the imperfect development of the muscular structures and was analogous in every way to congenital torticollis in which the sternocleidomastoid is imperfectly developed. In the other case, the position of the shoulder is associated with an embryological condition, there being a distinct articulation between the upper angle of the scapula and the vertebra. In the first case the attachment of the trapezius to the spine of the scapula, both rhomboids, and the levator anguli scapulæ were divided, and the lower portion of the serratus magnus shortened. The scapula was brought down as far as possible and the tendons of the trapezius muscles reattached a little higher on the spine than normal, and the wound closed. In the second case an osseous band 1¼ inches long, ¾ inch wide, and ¼ inch thick extended from the upper angle of the scapula to the vertebral column with articulation at each end. Both were removed. Both cases were improved in appearance by operation, and function became practically normal.

Journal of the American Medical Association, Dec. 28, 1901.

Food Products from Diseased Animals.—D. E. Salmon says that the great difficulty in meat inspection is the question as to where to draw the line between meat that shall be passed as fit for food and that which shall be condemned. The great majority of carcasses are unquestionably good or unquestionably bad, but between these extremes there are all shades of gradation. He does not believe that female animals in advanced gestation are proper for food. Females in which parturition has recently occurred are also under condemnation. Certain animal parasites render the flesh of the affected animals positively dangerous (echinococcus, trichina, tænia, etc.). The author enumerates the various ways in which tubercle bacilli may enter the body through food and drink. He believes that the bacilli may be present in the milk, although there are no signs of tuberculosis of the udder.

New York Medical Journal, December 28, 1901.

The Prevention of Laceration of the Perineum in Labor.—This forms the title of three separate papers. G. B. Finchell says that when a child is to be born the oval vulvar opening is not stretched as by an entering wedge.

but by having the lower end pushed away from the upper. That is, if, in the swinging of the head, as it extends, it *slides* on the perineum, the space between the pubes and the fourchette will increase; on the other hand, if the head *does not slide* during this swing the opening will not increase and the perineum will follow the motion of the head. This causes a decided stretching of the perineum, but no increase in the size of the vulvar opening. The perineum under such circumstances may become very thin and get ready for a nasty stellate tear. Different degrees of this sliding will occur in different cases. Even with perfect sliding, a precipitate labor may cause a split. The more perfectly this mechanism is carried out, the safer will be the perineum. Consequently it is of primary importance to keep in the vagina a lubricant to facilitate the normal extension. The natural lubricant is the best and should be preserved. Consequently douches, and especially antiseptic (usually irritating) douches, are to be avoided except when their use is imperative. Digital examination removes a great deal of the lubricant and gets the perineum ready for a tear. External palpation should be practised more. The vast majority of digital examinations made during labor are without reason. Artificial lubricants do not replace the natural one.

M. A. Walker advises the removal of all possible aids to the action of the abdominal muscles. Too precipitate delivery is to be prevented by pressure against the vertex. This pressure is applied, the patient being recumbent, with the fingers pointing posteriorly and pressing against the (maternal) posterior segment of the head during each pain. This manœuvre increases flexion and retards the entire head, while it allows of some anterior or pubic motion of the part, thus presenting the smallest diameter of the "passenger" to the vulvar ring, allowing time for the passage to be made larger, and directing the "passenger" through the axis of the outlet instead of permitting a large part of the uterine force to be expended directly on the perineum. In many cases a modified Walcher's position, resting the hips on the edge of the bed, the feet being on the floor, is of value in protecting the perineum, not only on account of its relaxing effect on that part, but also because it permits easy and constant observation of the parts. An anæsthetic is required toward the end of the second stage, not so much for the purpose of simple analgesia as for its property of preventing voluntary and lessening involuntary muscular contraction in case of endangered perineum. In the intervals between pains, the hand that has been used to retard, flex, and push forward the head may be consigned to the duty of peeling back the perineum from the head, and delivery should take place after the pain has terminated, while everything is relaxed.

J. L. Andrews analyzes the mechanical forces in labor and says that the whole subject of the prevention of perineal laceration may be summed up in a few words by: (1) Patiently and persistently endeavoring to bring the longest diameter of the presenting part in relation with the longest diameter of the outlet, and (2) Securing perfect dilatation of the soft parts at the outlet. Anæsthesia is to be freely used, and the head kept well flexed by pressure upon the occiput through the perineum. Extension should be allowed slowly. The ideal emergence of the head is between pains. The vulva must be accessible to sight and touch. Proper use of the forceps will often prevent laceration.

Medical News, December 28, 1901.

On the Rôle of the Prostate Gland in Gonorrhœa.—Frederic Bierhoff believes that there is probably no other condition so often responsible for the persistence of a gonorrhœal urethritis as an involvement of the prostate gland. He refers to 151 of his own cases of posterior urethritis in which he found the prostate involved in every case. This complication is supposed to develop generally in the third week of a gonorrhœa. The development of posterior urethritis and prostatitis is favored by any condition that causes congestion of the deeper urethra, or which introduces the living microorganism into the posterior urethra and ducts of the prostate. He believes from his experience in palpating the prostate, that a large percentage of adult males suffer from catarrhal changes of this gland whether they have ever had an attack of gonorrhœa or not, and that these changes are easily perceived by palpation. The two chief etiological factors of this condition are masturbation and coitus interruptus. The order of infection is probably as follows: Involvement of the anterior urethra; extension past the compressor along the chronically congested mucous membrane of the bulbous, membranous, and prostatic urethra, to the prostatic ducts, and on to the walls of the gland or its interstitial connective tissue, or even the periglandular tissue. In the more acute forms of gonorrhœal prostatitis, the neck of the bladder is regularly involved. In the male the diagnosis of gonorrhœal cystitis should never be made without a previous careful examination of the prostate. The prognosis is, on the whole, good.

The Neurotic Element in Infantile Eczema.—Jerome Kingsbury declares that disturbances of the nervous system comprise an important etiological factor of eczema, and will also intensify a previously developed attack of this disease of whatever type it may be. For general purposes the writer classifies these neurotic elements caused by reflex action as gastrointestinal, sexual, and local nerve irritation. Of the latter class, that of teething infants is the most striking. Perhaps dentition never produces a true eczema, but it is often observed that with the eruption of each new tooth, the eczema is much aggravated. Irritation from the alimentary canal, however, is a far more important cause than dentition. The quantity and quality of food often given to infants is indeed appalling. But neither does the breast-fed infant escape. It is often just as necessary to treat the mother as it is the child. Tea should be cut down to the minimum, and beer and ale must be forbidden. The presence of pin-worms in the rectum or even in the vagina should be considered. The penis and clitoris should always be carefully examined. All constriction of these organs should be removed. When merely adhesions exist, a well-oiled probe should be passed around the entire surface of the glans, after which the prepuce can be retracted, and the smegma cleaned out. When necessary, circumcision should be insisted upon. In each case the exciting cause must be searched for and removed.

American Medicine, December 28, 1901.

Nephritis in Malaria.—John T. Moore concludes that: (1) Nephritis is not likely to occur in a single tertian infection for a short interval, say of five days; (2) A double tertian infection will produce a nephritis in a large percentage of cases, if it runs only for a short time. This percentage has been estimated at 80, but the writer thinks this too large; (3) The more chronic any case of infection becomes, the more likely is the occurrence of nephritis; (4) Malaria of long duration, or often-repeated attacks, will produce chronic renal disease, as shown by continuous presence of albumin and casts; (5) Estivo-autumnal malaria probably gives the greatest percentage of cases of nephritis, viz., 68.7. (6) The age of the patient, height of temperature, or specific gravity of the urine showed no relation to the presence of albumin and casts in the writer's cases.

Trophoneurosis Affecting the Hair.—F. Savary Pearce reports this case. The patient is an American woman twenty-seven years old. Formerly her hair was heavy and dark brown in color, while her eyebrows and lashes were jet-black. For two years the hair had been falling out rather freely. Ten days before the rapid alopecia developed, she caught a hard cold in the head, followed by a herpetic eruption of the face, the back of the neck, and the region about the mouth. There was severe itching of the face and vulva. The ears and dorsum of each arm were red and swollen. The rapid alopecia began on November 18, 1900, and within three weeks her hair rapidly fell out until all of it with the exception of a few hairs on the temporal and occipital regions had been shed. These were shaved off and massage and electricity were applied to the scalp. Two months later the hair had grown an inch and was snow-white. The eyebrows and upper lashes were white, but the lower ones and the hairs upon the arm were brown. In April, 1901, there was a recurrence of the herpetic attack and the white hair began to come out freely, but not to the same extent as at first. No medicinal treatment had any effect on the white hair. Semi-rest treatment very much helped the neurasthenic condition. The static breeze applied to the scalp did not have any effect in renewing the color of the hair. In October, 1901, there were a few black hairs on top of the head. There are marked dyspeptic symptoms, a sense of heat in the head, and a chronic otitis media, with discharges and progressive deafness. Her hands are subject to vasomotor attacks. There is no history of a hereditary predisposition to white hair. The nails apparently have not been affected. A trophoneurosis seems best to explain the development of the alopecia and whitening of the hair.

Massive Infiltration Anæsthesia with Weak Analgesic Solutions (Modified Schleich Method).—Rudolph Matas describes an improved apparatus for massive infiltration anæsthesia. After considerable experience, he concluded that a glass bottle for the solution was unsafe, as the pressure necessary to force the fluid into chronically inflamed tissues was apt to break the bottle. The present receptacle consists of a polished copper cylinder, nickel-plated on its outer and inner surfaces, 8 inches in circumference and 5⅝ inches in length. On the top is a metal tubes, allowing the air to enter and the fluid to escape, both ends of these being provided with stopcocks. The cylinder holds 15 ounces, but only 10 ounces of fluid are used, so as to allow enough space for the air charge. The fluid is introduced into the cylinder through the bottom, which is tightly closed. There is a glass water gauge to indicate the amount of fluid which is being used. The pumping outfit consists of the smallest bicycle hand pump. This is attached to a small metal cylinder filled with sterile absorbent cotton, used as a filter for the air injected into the reservoir. After the sterilized solution has been placed in the receptacle this is charged with air until the pump meets marked resistance. The attachments to the filter and pump are then screwed and the apparatus is ready for use. The injection needles are of various sizes, lengths and curves. The rubber tubing which connects the cylinder and needle is about 15 inches long. The advantages of this apparatus are: That it allows the operator to infiltrate and systematize large areas rapidly, continuously, or interruptedly without delay caused by recharging or exchanging syringes; that by the use of long needles it tends to diminish the traumatism caused by frequent punctures made necessary by the shorter needles used with the ordinary quickly exhausted syringes. The rapidity and thoroughness of the work as accomplished by the use of this apparatus are astonishing.

Philadelphia Medical Journal, December 28, 1901.

The Relation of the Middle Turbinate Body to Chronic Diseases.—Charles H. Baker calls attention to the great influence that the middle turbinate has upon the course and progress of nasal disorders. The indications for removal of this body are: The presence of polypi which cannot be seen till the middle turbinate is removed. Sinus occlusion by swollen membrane which is not yet polypoid and which does not respond to other recognized modes of treatment by cleansing and disinfection. Fetid crusting of the discharges in the upper portion of the nasal chambers in nonspecific cases. The so-called "bullous" hypertrophy of the bone. The close proximity of the body to the most sensitive area of the nasal mucous membrane so that when contact occurs, various disturbances of the nervous system arise. Vasomotor rhinitis, running along into other than the normal period of the year, which is attended by sneezing, asthma, cough, etc. The writer then describes his method of operating.

Cystic Liver.—Israel Cleaver describes this organ, whose dimensions were: Width, 12½ inches, the left lobe being 4 inches; vertical length 8 inches, and thickness 5½ inches. That part of the cyst projecting above the surface of the liver measured 7½ inches in circumference, occupied the under surface of the right lobe and crowded the gallbladder, which was also much enlarged. Another cyst, the size of a walnut, was sessile on the upper margin of the left lobe. There were four more of the size of hulled shellbacks, on the surface of the same face at the right of the large cyst. The gall-bladder contained twenty-six calculi varying in size. Sections of the liver in parts not occupied by the cysts macroscopically looked normal. The patient from whom the specimen was taken was a man eighty-one years old, never intemperate, and for the last sixty years, a teetotaler. Eight years previous to death he began to be troubled with rheumatoid arthritis which gradually grew worse. Later the tongue became heavily coated, sometimes with a brown crust, but it was generally white or somewhat yellow. The bowels were constipated, but the stools were of normal color. A few weeks before death, the right hypochondrium showed enlargement. Enlarged liver was diagnosed. There was no jaundice at any time. At this time there was first noticed an elevation of the surface about the size of an egg, 1½ inches to the right of the median line and below the ribs. It was fluctuating. Distended gallbladder was the diagnosis, and was confirmed by the consultant. Autopsy revealed the true state of affairs.

Berliner klinische Wochenschrift, December 9, 1901.

Westphal-Piltz Pupil Phenomenon.—A. Westphal reiterates his assertion that the contraction of the pupil which takes place when the eyelid is closed is complementary in nature. Schanz has supposed that it is due to mechanical causes, originating in the uneven pressure of the orbicularis muscle upon the eyeball. Animal experimentation shows that this is not the case, as mechanical irritation of the eyeball fails to produce a contraction of the pupil. It has also been claimed that it is produced, reflexly, by an irritation of the sensitive nerves of the eyeball. While this explanation may hold true for doves, it fails to account for the phenomenon in man. This has been proven as the result of much experimentation. It is not possible in the present knowledge to say whether or not this phenomenon may be utilized from the standpoint of diagnosis.

Present Status of Light Therapy.—A. Bang says that physiological researches have established the following facts: (1) The violet and ultra-violet rays produce a specific inflammation of the skin which is different from all other cutaneous inflammations. (2) These rays stimulate the body as a whole, chiefly acting in a reflex manner. (3) These rays possess strong bactericidal power. Much has recently been written in regard to the satisfactory results obtained in the treatment of constitutional diseases by light. Astonishing results have apparently been obtained in this manner in the treatment of pulmonary tuberculosis, syphilis, arthritis, diabetes and a number of other diseases. In most of the cases of such conditions hitherto reported as treated by light, other therapeutic measures and various climatic influences have been brought into play. For this reason it is at present impossible to say exactly what value light therapy possesses when employed in constitutional pathological conditions. That some benefit is to be derived therefrom seems certain, but that in the future it is to work miracles in these diseases is not to be believed. At present it is in local cutaneous and tissue affections that the benefit of light therapy is the most satisfactorily observed. It possesses a specific influence over lupus vulgaris. Of 640 cases of this disease so treated by Bang, 456 were entirely cured. No recurrence has taken place in 130 of these, although from one to five years have elapsed since their recovery. In only eleven cases was it necessary to discontinue the treatment on account of unfavorable signs. Cases of lupus erythematosus, alopecia areata, acne vulgaris and nevus vascularis have also been treated by this method with good results. The efficiency of light in the treatment of disease is very largely dependent upon the so-called chemical rays of the spectrum. In the majority of cases, the heat rays are directly injurious. For this reason all apparatus for the therapeutical administration of light should be so constructed that a maximum number of chemical rays and a minimum amount of heat rays reach the patient. In most apparatus now in use the heat rays are not sufficiently excluded. Bang has devised a mechanism which seems to fulfil all the necessary requirements. By its use he obtains in five minutes, with eight amperes and 40 volts, a light reaction of equal intensity to that produced by other forms of apparatus with 60 to 70 amperes and 55 volts in 1¼ hours. The bactericidal power of the light thus obtained is exceedingly great, far exceeding that produced by any other so-called "light-machine."

Münchener medicinische Wochenschrift, December 10, 1901.

Nature of the Temperate Elevations Following Muscular Exercise Observed in Phthisical Patients.—A. Ott confirms the observations of Hochstetter and finds that in all cases non-febrile phthisical patients show an increased body temperature as the result of physical exercise. The question is whether this increased temperature is to be regarded as a febrile process due to pathological causes or is to be considered as a mere physiological process. In order to solve this problem, he utilizes the established fact that albumose occurs in the urine in 90 per cent. of all fevers. He selected twenty-five non-febrile phthisical persons. These were made daily to take a walk of prescribed length. Temperature observations and urinal examinations were made before and after this exercise. In nine of these albumose was found in the urine after the exercise. In ten a doubtful result was obtained. In the remainder no albumose was present. It is probable that in the ten cases where the result was doubtful, albumose was present in the urine in too small an amount to be detected by the test used. Ott believes as the result of these observations that the increased body temperature present in such cases is of pathological origin and that in all instances the exercise prescribed for phthisical patients should be so regulated that a minimum increased temperature results therefrom.

Gelatin Injections in Pulmonary Hemorrhage.—A. Hammelbacher and O. Pischinger report two cases of hæmoptysis which they treated with subcutaneous injections of gelatin. Two-and-one-half-per-cent. solutions were used. In both a favorable result was obtained. In neither case was a single injection sufficient to control the hemorrhage permanently. For this reason several injections were given on successive days. The symptoms following this treatment were the same in both cases. There were a temporary rise in temperature and pain and discomfort at the site of the injection. These, however, quickly disappeared. Immediately following the injections there was present a peculiar taste which was described as being similiar to that of sealing wax. The hemorrhage was immediately relieved, although after a variable time (a few hours or days) it reappeared. Only by continuing the injections was it possible to relieve the conditions permanently. In cases in which it is impossible to control hæmoptysis by other means, the use of gelatin injections is advised provided the gelatin solution is absolutely sterile, and proper antiseptic precautions are observed.

Causation of the Primary Apex Localization of Pulmonary Tuberculosis.—Dr. Schmorl says that the primary apex localization of pulmonary tuberculosis may be explained upon anatomical grounds. As is well known, Birch-Hirschfeld has shown that in the vast majority of cases the initial portions of the lungs affected are those supplied by the third, fourth, and fifth bronchi of the upper lobe. This he ascribes to the small respiratory capacity or power of this portion of the lung, which favors the retention of infected particles which may become lodged therein. Schmorl believes that the cause of this diminished respiratory power and the peculiar arrangement of the smaller bronchi found in this portion of the lung is to be ascribed to a furrow on the surface of the lung which runs from the apex of the lung behind and above, downward and forward. He has observed this furrow in numerous autopsies. The pleura covering the furrow is slightly thickened, but no adhesions to the thorax wall are present. Oftentimes the depression is a mere line, but frequently it is well developed, distinctly separating the apex from the contiguous portion of the upper lobe. It is believed that the chief factor in the production of this furrow is deficient development of the first rib. In this manner, pressure is produced upon the expanding lung. In the majority of instances, persons in which this furrow is well developed show either apex tubercular deposits or a catarrhal inflammation in this location. This has been amply demonstrated as the result of numerous post-mortem examinations. A point which is apparently against the opinions here expressed is the fact that in children this furrow is well marked, yet in them beginning apex tuberculosis is rare. It is thought, however, that here the great elasticity of the first rib allows extensive expansion of the apices, and thus the injurious consequences of the furrow are overcome.

Deutsche medicinische Wochenschrift, December 12, 1901.

Employment of the Danysz Bacillus for the Extermination of Rats.—Rudolf Abel has undertaken experimental work in order to ascertain whether cultures of the Danysz bacillus can be successfully employed in the extermination of rats. As is well known, this bacillus was isolated by Danysz from field mice during a fatal epidemic among these animals. It is also pathogenic for rats, but not for the various domestic animals and man. Abel obtains irregular results by feeding agar cultures of these organisms to rats. In some cases, death promptly followed, but in many others the animals remained sound. It is certain that the continued transmission of the bacillus from rat to rat causes its virulence for these animals to be greatly attenuated, so that very soon it entirely loses its pathogenic properties for them. It cannot, therefore, be recommended as a reliable agent for their destruction. It is probable, however, that by feeding rats on large amounts of fresh agar cultures a reduction in their number may be obtained in regions where they greatly abound. Since the destruction of rats is of prime importance in those countries where plague is prevalent, further work along this line is greatly to be desired. In this manner the most favorable conditions for the employment of this organism can be ascertained.

Expulsion of Fibrin-like Bodies in the Urine.—Alfred Rothschild reports the interesting case of a patient who expelled in his urine a sausage-shaped, fibrin-like body about ½ cm. in diameter and the length of the little finger. Previous to the expulsion, there had been intermittent attacks of hæmaturia accompanied by symptoms of bladder irritation. The general condition was good. The urine was normal, with the exception that at times 5 per cent. albumin, a few red blood cells, and fibrinous threads had been observed therein. The expelled fibrin-like body was sectioned and submitted to microscopical examination. When it was stained with hæmatolin-eosin, there was observed a dark, homogeneous external layer, which contained scattered epithelial cells. The internal portion was also homogeneous in character, but much lighter in appearance, and contained no cells. Weigert's fibrin stains gave a negative result. From this examination it was thought that the body had its origin from a tumor located somewhere in the urinary passages. Palpation gave negative results. Cystoscopy showed no abnormality, except a hypertrophied prostate. The patient was lost sight of for about six months. At the end of that time he returned for treatment. He had become very much emaciated, and was in poor general condition. The urinary examination gave results identical with those previously obtained. Cystoscopy showed that the left ureter was discharging no urine. Palpation showed the presence of a tumor in the left kidney region. Nephrectomy was performed. There was found a tumor of the left kidney which involved two-thirds of that organ and protruded into the pelvis of the kidney, completely blocking up the ureter outlet. Microscopical examination showed that this tumor was a sarcoma with giant cells. In addition, there was lodged in the ureter a body entirely similar to that which had been expelled six months previous.

Parasitic Nature of Carcinoma.—Alexander Katz says in answer to Ribbert's arguments against the parasitic origin of carcinoma that cell misplacement may be the starting point in the origin of this disease, but this does not necessarily imply that such is the single and essential cause of carcinomatous growth. The deteriorating differentiation of cells is a negative process. How is it possible that a negative process can give rise to such a measureless cell proliferation as is seen in cancerous growths? It is true that in human pathology we are unacquainted with any irritative factor which can cause unlimited cell proliferation, but this does not prove that such a factor does not exist, and we must presuppose its existence until this is definitely disproven. As for the assumption that a symbiotic life between the parasite and the cell must always result to the detriment of the latter, it can be said that such is not borne out by comparative observations. Such favorable symbiotic life is known to occur in certain plant cells. Also the physiological process of fecundation is an example of such favorable symbiotic life. The fact that in carcinoma only a certain variety of epithelial cells is affected and that other varieties never become involved is at first thought a strong argument against the parasitic origin of the disease. It is, however, possible to suppose that in given cases certain varieties of epithelial cells are originally submitted to parasitic irritation and acquire certain properties thereby. These properties are then transmitted by inheritance to the subsequent daughter cells, and thus transferred to countless generations of such cells. According to this view an original parasitic irritation is necessary; but this need not be continuous, and the parasites may be absent in the fully developed growth and the metastases. Ribbert contradicts himself when he says that old age may favor the development of carcinoma, and in the next sentence claims that unhygienic conditions are the principal factors involved in its origin. Ribbert, in answer to the above, said that while he had always taught that the misplacement of cells was an important factor in the origin of carcinoma, he had never held that it was the only one, but that cell simplification was an important secondary factor. The separation of cells from their organic combinations is in no way a negative process. If in such a simplification in their structure takes place this is only a secondary appearance. The comparison of various plant tumors with carcinomatous growths is not permissible, as the former are decidedly of an inflammatory nature. Physiological fecundation is not to be conceived as symbiotic in character. The supposition that parasites are originally necessary for the origin of carcinoma, but subsequently unnecessary for its growth, is illogical from all sides, and is not likely to be accepted by the supporters of the parasitic theory, for they seek the organisms in the full-grown tumor and metastases. So far as the statistics are concerned he has already said that if cancer is actually on the increase this does not necessarily involve a parasitic origin. The validity of the statistics, however, is not sound, as a large portion of the same has been gathered without pathological foundation.

French Journals.

Concerning the Action of Sodium Sulphate on Contractions in Tetanus.—A. Gelibert reviews the experimental work on this subject, and then gives an account of two cases which they have recently treated, and which terminated in a cure. One patient was a boy of six years, the other sixteen. The most striking feature of this treatment was that after the first injections of the persulphate the patients rested easily and passed a good night, although after the administration of chloral and bromide they were able to get only a few minutes of consecutive sleep. After the first injections of the persulphate the spasms which were so painful, and which were caused by movement or which occurred spontaneously, disappeared completely. The contractions began to diminish on the second day of treatment in one case and on the third in the other. Their complete disappearance took place at the end of seven days in one patient and at the end of ten days in the other. The injections appeared to improve the general condition also. The solution should always be fresh and never be stronger than 5 per cent.—*Lyon Médical*, December 15, 1901.

A Foreign Body in the Œsophagus; External Œsophagotomy; Cure.—Leon Labbé reports this case of a man thirty-five years old who swallowed a dental plate containing five teeth. The physician first called ordered [illegible] as all efforts to [illegible] the patient were unsuccessful he was taken to [illegible] under the care of the writer. After [illegible], operation was [illegible] upon, and external œsophagotomy was performed. The writer concludes after a recital of the case that [illegible] should be [illegible] as they rarely serve to expel the foreign body, while [illegible] attended by danger of [illegible] of the [illegible], and [illegible] perforation at the point of contact of the foreign body. Attempts to remove the body by the mouth should not be persisted in as they are not without danger and are frequently unsuccessful. As soon as the [illegible], external œsophagotomy should be performed even if the body is in the upper thoracic region, which is generally accessible by cervical [illegible]. It is [illegible] the [illegible] it is not without its [illegible]. It is [illegible] the wound after the operation to feed the patient. The writer [illegible] passed through the nose. These [illegible] can take place [illegible] of the wound. The wound in the [illegible] should be [illegible] directly over the œsophagus.—*[illegible]*, December 14, 1901.

A Typhoid Form of Generalized Staphylococcus Infection.—[illegible] describe this case. The patient was a [illegible] aged thirty-three years. He was of robust appearance, but [illegible]. For fifteen days he had had headache, epistaxis, fever, [illegible], and a yellow fetid diarrhœa. [illegible] developed. He was dull and responded slowly to questions. His tongue was [illegible] red on the borders and white in the center. The abdomen was distended. The liver and spleen were enlarged. The pulse was rapid, soft, and compressible. The face was cyanosed, dyspnœa increased, and death occurred before [illegible] had been tried. At autopsy the kidneys, the liver, the spleen, and the mucosa of the ileum in the neighborhood of the cæcum showed an eruption of small whitish nodules, surrounded by a hemorrhagic areola. The brain was congested, and presented on its convexity some ecchymoses. Histological examination showed these nodules to be staphylococcic embolisms. The port of entrance of infection was uncertain. In general, it is through the skin that this microorganism finds access to the organism.—*La Presse Médicale*, December 14, 1901.

A Case of Latent Spina Bifida with Unilateral Trophic Troubles and Lumbar Hypertrichosis, with Metameric Distribution.—Gangolphe and Pinatelle report this interesting case. The patient was a man of twenty-seven years. He entered the hospital to have a revolver ball removed, and his condition was then discovered and studied. He was a degenerate physically, with various anatomical stigmata. He was brachycephalic, the forehead tapering, the cheekbones prominent, while the helix and lobule of the ear were atrophied. He was small of stature, with arrested development of the trunk, and thoracic malformations. No longitudinal fissure could be determined, but the lumbar vertebræ from the second, appeared sunken, indistinct, and without distinct intervertebral discs. There was evidently spinal malformation. Trophic troubles associated with spina bifida are frequent and varied, but they are almost invariably bilateral. The unilateral distribution in this case is most interesting. In the metameric distribution of the hypertrichosis there is another important sign. The lumbosacral location is a most valuable diagnostic point of latent spina bifida. The absolute latency of the spina bifida marks this case as very unusual.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, December 15, 1901.

Therapeutic Monthly, November, 1901.

Therapeutic Action of Nitroglycerin; A Valuable Drug for Relieving Muscular Spasms.—H. E. Randall declares that nitroglycerin is one of our most valuable drugs, but it should always be used with caution and with knowledge of exactly what it is desired to accomplish. In muscular spasm, as in hysteroepilepsy, puerperal eclampsia, tetanus, spasmodic asthma, as well as in renal and gallstone colic, nitroglycerin promptly relieves some of the pain. In paroxysms of hysteria with cold hands and feet it acts like magic. The drug in hysteria is worthy of a more extended trial. The writer usually gives it in [illegible] or [illegible] grain tablets, repeated in five minutes if necessary.

Yeast Treatment of Leucorrhœa and of Gonorrhœal Vaginitis.—[illegible] Chapelle ascribes to the method of treating with yeast chronic leucorrhœa and vaginitis due to gonorrhœal infection considerable success. It should be tried in obstinate cases which do not yield to tonics and the usual local treatment. The desiccated form may be used as a pessary of cocoa butter and placed in position on going to bed, or as a paste made up with glycerin of starch and retained with a tampon of absorbent cotton. The quantity is not important, as it is perfectly harmless. The theory is that pure ferments, like yeast, attack pathogenic germs, allow themselves to be penetrated by them, and then destroy them by a true phagocytosis.

The Importance of the X Rays as a Means for the Early Diagnosis of Tuberculosis.—[illegible] calls attention to the value of the method, especially in [illegible], the [illegible], in many cases of pulmonary tuberculosis, and in all cases the [illegible] of the disease. He speaks of the phenomenon of tachycardia which is of so much importance in the early diagnosis of tuberculosis. This is seen in more than 64 per cent. of cases with great [illegible] with the [illegible]. This tachycardia is [illegible] rhythmical in the tuberculous patient. Another phenomenon is the [illegible] of the diaphragmatic [illegible] both in inspiration and expiration. In the [illegible] the phenomenon just mentioned is neither rhythmical nor symmetrical. If one side is healthy the diaphragm is seen to rise higher on this side than on the affected side. When the two lungs are affected the [illegible] is shorter on the worse side. From the revelations of radiography, the writer believes that the tuberculous heart is below the normal in size. He calls attention to the frequency of tuberculosis in subjects with small hearts and narrow aorta. The intercostal spaces are also [illegible], as they are extremely narrow. The thorax in these patients is conical in form. The scapula and clavicle are also abnormal in shape. The ribs are disposed in roof-tile fashion. The writer then speaks of the greater extension of the heart toward the lines of Traube and Frerichs on the right side, and also the special form of the left ventricular border of the heart of these patients, which he compares to the deformed foot of a Chinese woman.

Bulletin of the Johns Hopkins Hospital, November, 1901.

Congenital Absence of the Abdominal Muscles, with Distended and Hypertrophied Urinary Bladder.—William Osler reports the case of a boy, aged six years. In erect posture the attitude is remarkable. It is fuller on the right side than on the left. The navel appears stretched and distended. It is linear, and below are crow's feet. The attachment of the recti to the sternum and costal margin can be seen above. The skin over the abdomen is thin, the veins a little prominent. In the recumbent posture, coils of intestines can be seen in peristalsis. He cannot raise himself without turning over. The lower part of the sternum is thrust forward, forming almost a right angle with the xiphoid. The deficiency in the abdominal muscles and the high position of the bladder are associated conditions due to arrest of development.

On a Family Form of Recurring Epistaxis, Associated with Multiple Telangiectases of the Skin and Mucous Membranes.—William Osler reports this very rare condition, which has nothing to do with hæmophilia. Two of the three cases reported belong to a family seven members of which were afflicted with epistaxis. The attacks had occurred since boyhood. The second patient died, and autopsy revealed angiomata in mucous membrane of the nose and stomach. The septum of the nose showed many large dilated veins just below the epithelium. The third case had also had attacks of epistaxis since the tenth year. The telangiectases were most numerous on the face, which they greatly disfigured. The angiomata were scattered over the body. Angiomata have a curious relationship with affections of the liver.

Tuberculous Dacryoadenitis and Conjunctivitis.—Edward Stieren declares that: (1) Tuberculosis of the conjunctiva may be either ectogenous or endogenous; tuberculosis of the lacrymal gland must be hematogenous. (2) The presence of the tubercle bacillus in tuberculous conjunctivitis and tuberculous dacryoadenitis is not a *sine qua non* of the disease. In the present case repeated examination of the matter from the ulcers of the conjunctiva failed to show the presence of tubercle bacilli, nor did inoculations in animals produce the disease; (3) Tuberculous dacryoadenitis and conjunctivitis may undergo cure, surgical intervention is indicated only after therapeutic and proper hygienic measures fail, since it is a universally recognized fact that tuberculosis in other parts of the body is often cured outright spontaneously, the cure being effected by a marked increase of connective tissue.

Osteitis Deformans with Report of a Case.—Arthur W. Elting concludes: (1) That osteitis deformans is a chronic disease of the bones which develops in middle life or later; (2) That the disease is of more frequent occurrence than is generally supposed; (3) That the onset is insidious, sometimes in a single bone, but usually manifesting a tendency to symmetrical involvement of the bones; (4) That there is an especial tendency to involvement of the tibia and femur as well as the frontal, occipital, and parietal bones; (5) That it attacks both sexes and does not appear to be related to any constitutional disease; (6) That the etiology is not understood; (7) That it requires from five to fifteen years to reach its maximum development; (8) That it is characterized by hypertrophy and deformity of the bones involved, either with or without pain. (9) That it is characterized microscopically by a rarefying osteitis combined with new bone formation; (10) That the duration of the disease is indefinite, and that the disease has but comparatively little influence upon the general health, and furthermore that it is not a direct cause of death; (11) That treatment must be purely symptomatic.

Zeitschrift für klinische Medicin, Bd 44, *H.* 3 *und* 4.

Enlargement of the Hands and Feet of Neurotic Origin.—Hans Hirschfeld reports three interesting cases of chronic enlargement of the hands and feet evidently of neurotic origin. All three cases were fatal. It is possible that they were related to those conditions known as erythromelalgia and acromegaly. The most striking symptom present was a symmetrical enlargement of the hands and feet. This was not due to enlargement of the bones of the involved regions, nor was muscular hypertrophy present. The principal anatomical lesion was increased in the thickness of the cutaneous structures. In two cases, cyanosis and intermittent œdema of the affected extremities were present. There was also a drum-stick deformity of the extremities of the phalanges. Intermittent pains were present in all cases. In only one case was it possible to establish, with surety, the primary pathological lesion. Here an interstitial neuritis of the larger nerves of the involved extremities was present. After reviewing the literature of allied diseases the author concludes that the symptom complex of these cases shows the greatest similarity with the disease known as osteoarthropathie hypertrophique pneumique, previously described by Marie. The pathology and etiology of the condition are obscure, and can be elucidated only by the observation of a large number of cases.

Pulsus Alternans.—Under this name K. F. Wenckebach describes an alternating condition of the pulse in which a powerful pulsation is regularly followed by one of greatly diminished intensity. He reports the case of a man twenty-six years of age, in which such a pulse was observed following an attack of influenza. Arterial sclerosis of a medium grade was present, but no organic heart lesion. In the course of time the pulse regained its regularity, except during periods of muscular activity. By auscultation it was found that corresponding with the high and low pulse waves the heart sounds were of increased and lowered intensity. As a rule there was a shorter interval between the strong and the weak sounds than between the weak and the strong. That is to say, the weak sound antedated itself. If at any time the lower pulse wave became imperceptible to the finger, only the higher pulse waves were felt, and an apparent regularity was established. Auscultation, however, showed that this was a misapprehension, and that the characteristic alternating heart sounds were present. The pathology of this form of pulse is somewhat obscure. It is probable that for its occurrence a hypodynamic condition of the heart muscle is necessary. Even in such, however, so long as the rhythm remains normal, a regular pulse is present. When, for any reason, the slightest arhythmia occurs, an alternating pulse is immediately observed. In this condition a stimulating impulse reaching the heart too soon finds the weakened muscle unable to respond promptly, and thus a weakened contraction is produced. For the production of pulsus alternans, then, two factors are necessary: (1) Reduced tone of the heart muscle, and (2) Abnormal rhythm.

Revue de Chirurgie, December 10, 1901.

The Reflex in Gastro-Enterostomy.—G. Tavel writes of the incoercible or severe vomiting which is so apt to occur after gastro-enterostomy, and describes the various operatory modifications proposed for its relief. The simple operation of gastro-jejunostomy does not prevent the reflux. Concomitant entero-anastomosis is fairly efficacious, and entirely so as performed by Roux, who divides the jejunum and implants the duodenal end about 10–20 cm. above the opening of the peripheric end, which in its turn is fixed to the posterior surface of the stomach. Gastro-duodenostomy, where possible, will also prevent reflux.

Tuberculous Rheumatism or Infectious Pseudo-Rheumatism of Bacillary Origin.—Patel states that in tuberculous infections there are often found certain articular troubles which have hitherto been considered of rheumatic origin, but which are really due to bacillary intoxication. They consist of symptoms simulating arthralgia, chronic-articular and nodular rheumatism, and rheumatism deformans. Pathological anatomy and positive inoculations have confirmed the statement. Tuberculous toxins are able to produce a variety of lesions in the joints, from simple arthralgia to the classic tumor albus, lesions varying in severity according to the virulence and number of the bacilli, the general condition of the patient, and the local condition of the joint affected.

Subserous Appendectomy.—Vignard says that in internal operations, the appendix may be quite free, or else, on the contrary, deeply buried in adhesions. The latter condition is fraught with difficulties and dangers, which are almost entirely obviated by subserous appendectomy, by which he means ablation of the appendix after stripping from it its peritoneal sheath. Instead of laboriously searching for the extremity of the organ, with the risk of tearing or breaking some unsuspected abscess, one need merely draw out the base of the cæcum and pass the finger along the three longitudinal bands which surround it and which lead to the base of the appendix. The serous covering is incised circularly at about two cm. from the base, then everted and stripped for about one and a half cm., at which point the appendix is ligated and cut. The stump is covered by the portion of the serous covering left behind, which is closed by a few stitches.

Revue de Médecine, December 10, 1901.

Pneumo- and Cardio-Paludism.—Naamé calls attention to a pulmonary condition sometimes found in malaria, consisting of symptoms indicative of consolidation of the apex of one or both sides, the most important, as a rule, being the absence of adventitious sounds, and the presence of an expiratory souffle. These characterize the onset of the trouble; at a later stage there is respiratory roughness and absence of souffle. The cardiac disorders often found in malaria are dilatation, a galloping, tricuspid diastolic sound, heard in the xiphoid region, and a divided pulmonary sound. There may sometimes be brachycardia. All these symptoms disappear under quinine treatment.

Articular Traumatism and Sensory Disturbances.—Chavigny reports twenty-one cases illustrative of the fact that sensory troubles frequently follow traumatism of the knee, even when the nerve trunk cannot have been involved. Traumatic hydrarthrosis of the knee is usually accompanied by hypoæsthesia all along the line of the crural nerve. Sensations of cold along the thigh are rather rare, having been found in only three out of twenty cases. Patients suffering from acute articular rheumatism did not have sensory disturbances, even when muscular atrophy was marked; this fact might serve as a diagnostic point between this and simple rheumatic arthritis.

A Study of Epidemics of Streptococcal Infection.—Raymond Bernard lays emphasis on the fact that the streptococcus is of itself capable of causing much injury, that it is in fact a specific agent. This specificity is not always apparent, but is seen and acknowledged in certain epidemics. The streptococcus is always with us, in the dust, in the air, and within our own organs and tissues. Under certain influences, these microscopic plants germinate, develop, and fructify. Thus in catarrhal diseases, cold causes a reflex congestion of the respiratory passages, which induces an increased secretion of mucus; this mucus provides the necessary culture medium for the streptococcus, and the result is what is known as "a cold" or "catarrhal trouble," but it is in reality a streptococcal infection.

Virchow and Berlin.—As regards the city of Berlin's own peculiar debt to Virchow, a late number of *Die Woche* is authority for the statement that the city's magnificent sewer system was developed from suggestions made by Virchow in an official report in 1873. Virchow has also taken an active part in the building of Berlin's hospitals, and to the newest and finest of these the name "Virchow Hospital" has been voted by the authorities.

Double Crico-Arytenoid Arthritis from Grippe.—Mounier reports a case of this nature occurring in a boy of nine years. The attack began with general malaise and sore throat. There was extreme tenderness on pressure over the sides of the neck, corresponding to the situation of the cricoid cartilage, while both phonation and deglutition was extremely painful to the patient. Laryngeal examination revealed an inflammatory condition in the general crico-arytenoid region causing considerable dyspnœa. Revulsive measures applied to the neck externally and antirheumatic treatment internally led to a complete cure.—*Annales des Maladies de l'Oreille*, etc.

Society Reports.

THE WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Proceedings of the Eleventh Annual Meeting, Held in Chicago, December 30 and 31, 1901.

This association met at the Great Northern Hotel, under the Presidency of Dr. A. F. Jonas of Omaha, Nebraska.

An address of welcome was delivered by Dr. Alexander Hugh Ferguson of Chicago, to which an eloquent response was made by Dr. Joseph Eastman of Indianapolis, Indiana.

An Old Shoulder Dislocation, with Report of a Case.—Dr. J. Rudis-Jicinsky of Cedar Rapids, Iowa, read a paper with this title. The object of the author in making this report of an apparently simple case was to show what the x-ray could do for the profession in the investigation of injuries to the joints, in luxations, fractures, and in observations of the growth of the callus, the bones themselves, etc., and to furnish an aid in the interpretation of the x-ray findings. Before one could interpret correctly the fluoroscopic image or the skiagraph of certain parts when their relationships were altered by disease or trauma, he should have always before him a photographic picture of the normal parts and of their normal relations. After taking all the other precautions of a proper technique into consideration, one would not go astray. Moreover, the eye would be prepared to take in points which would otherwise not be seen.

After reporting a case at great length of an old shoulder luxation, the author dwelt upon the value of the x-ray in cases of fractures, etc.

Dr. Lewis Schooler of Des Moines, Iowa, indorsed the value of the x-ray in old dislocations of the shoulder, especially in cases where the swelling was so great as to obscure some of the landmarks and render the diagnosis difficult by the usual method. While in nearly all cases the examining surgeon could make a diagnosis with satisfaction without the aid of the x-ray, yet it was a consolation to have one's diagnosis verified by a competent operator of the x-ray machine.

Dr. Jicinsky, in closing, said the x-ray enabled one to determine through a plaster-of-Paris or any other dressing the exact position of the fragments, and whether the object sought, namely, the reduction of the dislocation, was accomplished.

Treatment of Irreducible Backward Dislocation of the Astragalus by Opening the Joint and Repositing the Same.—A paper on this subject was read by Dr. W. Jepson of Sioux City, Iowa. After detailing a case and going extensively into the literature of the subject, the author summarized his observations as follows: (1) His own experience and the results of recorded cases led him to believe that it would rarely be possible with present knowledge and technique to bring about a reduction of a backward dislocation of the astragalus without opening the joint and bringing about a reposition of the bone by direct manipulation. (2) With our present command of aseptic surgery he could see no reason why this should not be undertaken in all cases uncomplicated by severe infection, with good prospects of securing nearly a perfect result. (3) Removal of the astragalus should be reserved for such cases as where the bone was completely separated from its ligamentous attachments, consequently having no adequate source of blood supply. (4) If amputation be resorted to only when the dislocation was compound and infected to a degree impossible of removal, the patient's life was jeopardized by the septic intoxication of infection.

Some Internal Injuries of the Knee-Joint.—In a paper on this subject, Dr. M. L. Harris of Chicago called attention to two varieties of injuries to the inner structures of that joint, which, he believed, were more common than the attention hitherto given them would seem to indicate. These injuries could be produced in one of two ways. First, by the direct application of force, as might occur in a fall upon the knee, or by the forcible impingement of a more or less pointed object against this portion of the joint. Second, by pinching or crushing the apex of the meniscus in the angle between the femur and tibia, as might occur when these bones were slightly separated during hyperflexion or sudden squatting. The cases narrated by the author illustrated the serious and permanent disablement that might occasionally result from comparatively slight pathological changes affecting the inner structures of the knee-joint, and showed the necessity of operative treatment in these cases following an injury in which the characteristic symptoms persisted after the usual treatment of the joint by rest and immobilization.

Ankylosis of Joints.—Dr. John B. Murphy of Chicago read a paper on this subject, in which he recommended arthroplasty for the relief of ankylosis without destructive bone lesions. Ankyloses and contractures were of three varieties: First, atrophy of soft parts; second, union (fibrous and bony) between joint surfaces; third, a combination of one and two.

The essayist referred to the experimental work of Chlumsky of Wurzburg, who decided that the best way to relieve such joints was to treat them precisely on the same basis as one would non-union of fractures from the interposition of foreign material between the fragments. He experimented with several kinds of material, absorbable and nonabsorbable, to determine the best material to use, but finally abandoned the use of foreign materials and resorted to a plastic operation in the neighborhood of the joint for its relief. The method of Chlumsky was described, the essayist stating that he had adopted it in several cases with good results.

Treatment of Dislocation of the Clavicle Through Open Wound.—Dr. James E. Moore of Minneapolis, Minn., said that some recent writers had advocated the treatment of such a dislocation by wire suture, but he had been unable to find any literature upon the subject. Quite recently he had treated a case by cutting down upon the dislocated bone, replacing it and the surrounding soft parts, and fastening them there by means of silver wire and catgut sutures. The result was very satisfactory, and the findings were instructive.

Etiological Factors in the Production of Tumors.—Dr. George Halley of Kansas City, Mo., read a paper with this title. The origin of the term tumor went back to the infancy of medical knowledge, and simply meant a raised or elevated part of the body, unnatural, and only found in morbid conditions. The early concept was that something had raised or enlarged the part. Scientific investigations had been enlarging the scope of knowledge along the lines of etiology, hence tumors were very early divided into benign and malignant. No theory had been broad enough to account for all the phenomena characteristic of benign or malignant tumors. Inflammatory conditions that almost invariably produced some kind of tumefaction were for a long time regarded as the principal factor in their production. Many things, however, in the inflammatory conditions in no way comported with the ordinary processes found in tumor growths, and the products of most of the tumor growths were utterly unlike those of the inflammatory process. But as inflammation was believed to be principally due to irritation, it was held to be the prime factor in the production of morbid growths. The author dwelt at length upon the various forms of tumors.

One constantly occurring element in all benign tumors was the connective tissue. Sometimes it predominated and sometimes it was held in abeyance. Its presence was never wanting. Of all the tissues in the body, it most readily responded in physiological activity to irritating processes. In inflammatory changes it was found to be the reconstructing agent. It was not wonderful, therefore, that we had in this tissue the essential part, if not the entire mass, composed of this tissue. Was the connective-tissue germ-cell altered in quality? Had it been inoculated by a plastic material altered in quality by an irritant, or had there been a coalescence of protoplasmic germs from other tissues? We had not yet determined this, but he took it that along these lines, if not exactly, yet relatively near to it, would be found the true etiology of the benign tumor.

Surgical Procedures in the Removal of Fibromyoma of the Uterus.—A paper on this subject was read by Dr. Joseph Eastman of Indianapolis, Indiana. He said the morphology of the tumor and the environment of the patient should be considered before selecting the method to remove the tumor. Clay of Manchester, in 1844, operated for the first time for the removal of fibromyoma of the uterus. After speaking of the early history of removal of myoma of the uterus, Dr. Eastman described the first case that he operated upon, February 3, 1887; also the method pursued by him at that time, which can be found in the literature on this subject.

Myomectomy; Its Place in the Treatment of Fibromyoma of the Uterus.—This was the title of a paper read by Dr. O. Beverly Campbell of Chicago. The operation of myomectomy was not applicable to all cases of fibromyomata of the uterus, but could apply only to well-selected cases. This operation did not supplant panhysterectomy, hysteromyomectomy, and the different procedures for the relief of fibromyomata, but took its place as one of the recognized rational procedures, and as it was a conservative measure, it should be the favorite procedure when possible. A critical bimanual examination through the vagina and rectum under complete anæsthesia would usually admit of the diagnosis of cases amenable to this operation. All of the different varieties of fibromyomata, namely, the subperitoneal, the interstitial, and the submucous, may be treated by this method. By many operators it had been limited to the pedunculated subperitoneal variety. However, it had now been successfully applied to every variety of fibromyomata, with satisfactory results as to the immediate mortality rate and permanency of cure. The author concludes that myomectomy should be the preferred method in every case where possible to do so without extra risk to the patient, and where the ovaries can be conserved with the uterus. Operative interference should be advised in every case of fibromyomata where, after a careful examination, myomectomy was considered possible. The operation of myomectomy was, at all times, as safe in cases where it was applicable as hysteromyomectomy and panhysterectomy, and very many times almost a minor procedure practically free of risk. The early diagnosis of fibromyomata should be insisted upon, with a view of enlarging the percentage of cases in which myomectomy may be applicable.

Management of Uterine Fibromyomata Complicated by Pregnancy.—Dr. Miles F. Porter of Fort Wayne, Indiana, followed with this paper. After referring to the literature on the subject, and reporting an interesting case, the author concluded (1) That pregnancy was a frequent and serious complication of uterine myofibromata; (2) If, because of their size or location, they were likely to interfere with gestation or jeopardize the patient's life, they should be removed; (3) Each case was a law unto itself, and should be treated accordingly; (4) The tumor and not the pregnancy was the disease, and therefore any procedure which resulted in leaving the tumor and removing the pregnancy was unjustifiable. This, of course, was not meant to apply to those cases in which the fibroids did not interfere in any way, either with gestation or labor; (5) Pregnancy did not materially add to the risk of operations for uterine fibroids, so far as the mother was concerned; (6) The life of the mother, the life of the child, and the question of future offspring were the most important matters to be considered in reaching a conclusion as to the treatment of a case of uterine fibroids complicated with pregnancy.

The Treatment of Fibroids of the Uterus by Electricity and Present Status was the title of a contribution by Dr. Franklin H. Martin of Chicago. In the light of our knowledge, there was a time when the galvanic treatment of fibroids of the uterus by experts was legitimately the most conservative treatment possessed for a majority of those troublesome neoplasms. Now, the removal of fibroids with the knife by experts was the most conservative treatment for the majority of these difficulties. There was a time when the author submitted practically all his fibroid cases to the Apostoli treatment, because this treatment scarcely ever failed materially to benefit the patients; it symptomatically cured quite a large percentage, and occasionally the tumor seemed to disappear. It accomplished these results without subjecting the patient to a procedure which possessed any legitimate mortality. Gradually the evolution of the surgery for fibroids had reversed the relative position of the galvanic treatment. He considered vaginal and abdominal hysterectomies and myomectomies for fibroids, giving rise to serious symptoms, with their legitimate mortality reduced to 1 and 2 per cent., as remedies more conservative in their results than the treatment of the same tumors with electricity. He believed this, because hysterectomies and myomectomies, with a small percentage of risk, were the only remedies which absolutely relieved the difficulties in all cases. Electricity relieved frequently, symptomatically cured, but seldom actually removed, the tumor, and the treatment was tedious to the patient, and occupied much time of the physician in administering it. The present status of the electrical treatment of fibroids of the uterus was in his opinion that it had been properly superseded by surgery as a conservative remedy. He now recommended its employment in the following cases only: (1) As a local and general tonic, and as a relief of pressure and reflex pains and of hemorrhage in cases with complications contraindicating surgery; (2) In all interstitial fibroids where operative assistance was absolutely refused by the patient; (3) In tumors of small size of the interstitial variety in which hemorrhages were the principal symptom in women within one or two years of the menopause.

Dr. W. O. Henry of Omaha, Nebraska, thought that the electrical treatment of these tumors was overdone, and that to-day it was largely abandoned. As to myomectomy, where there were no complications requiring the removal of the tubes and ovaries, where the growth did not involve the entire depth or thickness of the uterus, so that this organ might be left intact, it was *the* operation to be performed. He agreed with Dr. Porter as to the removal of fibroid tumors that complicated pregnancy. As to panhysterectomy for uterine fibroids, he objected to it, as a rule. He thought it was better to save as much of the cervix as possible, thus securing a better vault for the vagina, and a better support for the uterus.

Dr. Van Buren Knott of Sioux City, Iowa, said that myomectomy as a conservative procedure in the treatment of neoplasms of the uterus needed no support. It was commonly accepted to-day as the method of election in cases in which it was applicable. He recalled a case of myomectomy performed on a woman three months advanced in pregnancy, who was subsequently delivered at full term of a healthy male child.

Dr. B. B. Davis of Omaha, Nebraska, said, as to myoma complicating pregnancy, that the tumor should be removed, if possible, before the woman became pregnant, but frequently patients consulted physicians with that complication. He indorsed practically all Dr. Porter had said in regard to the subject. He condemned the induction of abortion before delivering or removing the tumor, and mentioned a case in which he was called in consul-

[illegible] of the physicians recommending that that would be the best method.

Dr. C. H. Mayo of Rochester, Minn., mentioned the case of a woman, thirty years of age, upon whom he operated last June for a tumor complicating her first pregnancy. The tumor proved to be a degenerating fibroid with free fluid in the abdomen. The abdomen and tumor were much larger than the pregnant uterus. The tumor was removed, the woman made an uninterrupted recovery, and he expected later to be compelled to do a Porro operation, but in due time the woman was delivered of a healthy living child and recovered.

Dr. A. C. Bernays of St. Louis, Mo., expressed himself in favor of myomectomy where it can be done. He recalled two cases of very large fibroids in which he found that myomectomy was an excellent method of enabling him easily to make a hysterectomy. He believed that in both of these cases he could not have made a hysterectomy without making a myomectomy of the very large tumor first.

Dr. Charles H. Wallace of St. Joseph, Mo., was interested in the paper of Dr. Campbell, and said that myomectomies were of recent origin. Myomectomy was comparatively easy of performance in properly selected cases. As to tumors complicating pregnancy, he would follow the advice of Dr. Porter.

Dr. J. N. Warren of Sioux City, Iowa, combated the idea that myomectomy was an easy operation to do and without any particular danger attending it. He regarded it as a formidable operation, and always attended with considerable hemorrhage, excepting in the subserous variety, where there was a pedicle, and the surgeon could incise the serosa around it and simply peel the tumor out, but in the majority of cases where he had a combination of the interstitial and subserous varieties, it might be necessary to go through the entire thickness of the uterine wall; then it was not a simple operation. It was one that required not only great dexterity, but good judgment, in determining exactly the limits of the myomatous mass which was to be removed.

Dr. W. A. Tichenor of Chicago seconded the remarks of the last speaker as to the formidability of myomectomy. If there were one or two small tumors close to the peritoneal surface, it was not difficult to shell them out. On the other hand, if there were eight or nine tumors of fair size, and the surgeon undertook to remove them all from the surface of the uterus, he would get the uterus pretty well riddled with incisions for their removal, and it was not a safer operation, in his judgment, than a hysterectomy.

Dr. James E. Moore of Minneapolis, Minn., endorsed the paper of Dr. Campbell. All would agree that what was conservatism a few years ago was no longer conservatism. There was one point he wished Dr. Campbell had emphasized, namely, the possibility of doing myomectomy through the vagina. Within three weeks he operated through Douglas' pouch for the removal of a tubal pregnancy before rupture, and incidentally removed two fibroids, one of which was situated in the anterior wall of the uterus, well down toward the bladder, yet it was not difficult to remove it.

Dr. Donald Macrae, Jr., of Council Bluffs, Iowa, commended the paper of Dr. Campbell, and said it was the sinew of conservatism. These fibroid tumors should be operated upon and removed as soon as they are diagnosticated.

Dr. Lewis Schooler of Des Moines, Iowa, said the trend of the discussion seemed to be in the direction of operating on uterine fibroids by some method or other. He thought there was hardly a practitioner in the room who did not know of some of these fibroids having existed for ten or fifteen years in women without producing any disturbance. He did not think it was well to operate for their removal as soon as they were discovered. There were some women who had passed the menopause, others who were near it, and still others who would probably not give birth to children in whom these fibroids caused absolutely no trouble. Some of these cases could be let alone.

The discussion was then closed by the various essayists.

The Use of the Gall-Bladder as a Suspensory Ligament for Prolapsed Liver.—This was the title of the presidential address delivered by Dr. A. F. Jonas of Omaha, Nebraska. He said that the liver was sometimes displaced downward to a considerable degree, that there was usually modified function and a well defined clinical picture belonging to this change of position. Mrs. S., aged forty-one, had for three years suffered from paroxysms of severe pain located in the right hepatic region. These pains, always sudden in onset, sometimes subsided in the course of one or two hours, but occasionally continued until relieved by opiates. Whether they were relieved spontaneously or by anodynes, they were always succeeded by nausea and an aversion for food lasting for two days to a week. During the intervals she had a dragging pain in the right hypochondriac region. A year previously she had a moderate degree of jaundice. Otherwise her history was negative. On examination her abdomen was distended, tympanitic, the abdominal walls were pendulous, soft and flabby, and covered with numerous striæ, the result of child-bearing. On palpation, pain on pressure was elicited over the region of the gall-bladder, but no enlargement of that viscus could be made out. A movable lump was found between the right costal arch and the iliac crest, which proved to be the right kidney. The diagnosis was biliary calculi in the gall-bladder and movable right kidney. Cholecystotomy and nephrorrhaphy were recommended and agreed to by the patient.

After the usual preliminary preparations, a vertical incision was made, beginning at a point over the median end of the ninth rib, and extending down four inches. On entering the abdominal cavity, the lower margin of the liver was three fingers' breadth below the costal arch. The liver could very easily be elevated to its normal position, but it descended very slowly when pressure upward was released. In appearance it was normal. The gall-bladder was easily found, and several calculi could be felt through its walls. The displaced and movable kidney could be made out. The liver could be held in place by little effort, particularly when an ordinary amount of traction was made on the gall-bladder, so the question presented itself, Why not use the gall-bladder as a suspensory ligament? Accordingly, it was sutured in the uppermost part of the wound, snugly against the costal arch, the sutures passing through the gall-bladder wall, the parietal peritoneum and muscles. Before closing the peritoneal cavity, an exploration was made for the movable kidney, but it had receded to its normal position, and could not be displaced. The peritoneum was then closed, the remaining wound sutured in the usual way, save to allow for opening the bladder. This was done and several calculi removed. A long drainage tube was introduced and the wound was then dressed by an antiseptic, hygroscopic pad. The drainage tube was removed in one week. The wound closed at the end of four weeks. The patient was directed to wear a snugly fitting abdominal band. Subsequently several examinations were made. On percussion, the liver had remained in its normal position, and the dragging pain had disappeared. No displacement of the kidney could be made out, although she assumed several positions, straining in various ways. It was evident that the descended kidney was dependent on the descent of the liver. In this case, unfortunately, it was not ascertained whether there was associated a downward displacement of the stomach and colon. The author concluded: (1) The cause of hepatoptosis consisted in a modification of one or more of its normal supports, or an increase in the size and weight of the liver; (2) It was impossible for the liver to descend without producing a descent of the hollow abdominal viscera; (3) The utilization of the gall-bladder as a suspensory ligament to maintain and hold in its normal position a prolapsed liver, together with certain other abdominal organs, seemed practical.

Heart Suture.—Dr. B. Merrill Ricketts of Cincinnati, Ohio, made some remarks on this subject. He referred to malposition, displacement, and malformation of the heart, and then detailed a series of experiments which he had conducted on animals with reference to suturing the heart. He stated that there were twenty-seven cases of suture of the heart for wounds in human beings reported up to the present time, with recovery in seven instances. In this work it was necessary to use a suture that was longer-lived than ordinary catgut, and he had employed kangaroo tendon in ligating the coronary arteries and fine silk sutures in the walls of the heart. The sutures should be applied in systole of the heart, and not during its expansion. Certain hearts were softer than others; they broke down under the use of forceps, and forceps should not be used in this work. The indications for suturing the heart had to be worked out; but it was interesting to see how readily the chest could be opened with the right kind of forceps. He had used a kind of pruning forceps in his experimental work. He had opened the chest, reached the heart, and sutured it in forty seconds(?), and he did not think it would require much more time to do this in the human being. The aspirator should not be used for anything about the heart, because injury to the coronary arteries would often result in hemorrhage and death. The time had arrived when surgeons should no longer hesitate to open the chest for injuries of the lung and of the heart in cases of emergency.

Fracture of the Metacarpal Bones, and Oblique Fracture, Simple or Compound, of the Forearm.—Dr. W. W. Grant of Denver, Colorado, spoke of the application of Buck's extension in the treatment of fractures of the femur to fractures of the forearm and hand, although the application was as appropriate in certain inflammatory conditions of the wrist and elbow joints. He then detailed a case in which the second and third metacarpal bones were fractured near the metacarpo-phalangeal articulation; the third had a second fracture near the proximal end, and the fourth metacarpal also near the wrist was fractured; the ulnar artery was severed at the wrist, and the pisiform and cuneiform bones so badly damaged that they were removed. He obtained a very good result in this case.

Dr. John P. Lord of Omaha, Nebraska, narrated in an interesting manner some of the observations that he had made during a trip in Europe.

Total Extirpation of the Prostate Gland Through a Median Incision in the Perineum.—Dr. Alexander Hugh Ferguson of Chicago read a paper on this subject. In several cases operated upon by the author his results were better than he had ever secured by the suprapubic route.

Speaking of the advantages of the operation, he stated (1) That it was the most direct route to the organ, and that the prostate could be removed without injuring any important structure; (2) The operation was easily performed. In all those cases in which the gland had been repeatedly inflamed, it made it more difficult to operate, but not as difficult even then to remove the prostate from below as to do the suprapubic operation; (3) The removal of the gland, piece by piece, enabled the surgeon to work through a small opening, and prevented the bruising of the surrounding parts by the finger, which was accompanied with the removal of the gland *en masse* through the perineum; (4) Hemorrhage was avoided, so long as one was careful to work within the capsule. The hemorrhage in suprapubic prostatectomy, or in the combined method, was often very alarming. On one occasion the writer had to leave pressure forceps on blood vessels, and pack the bladder tightly with gauze twenty-four hours. The patient narrowly escaped death from both hemorrhage and sepsis. Perineal drainage after suprapubic prostatectomy was not as complete as when the prostate was attacked from below. It was found by the writer that the danger from septicæmia was not at all prominent after perineal prostatectomy, and so far had given no anxiety whatever. There was less danger of uræmia. The operation took the shorter time; the anæsthesia having therefore less effect upon the kidneys, and a minimum opportunity for sepsis made it easier for the kidneys to perform their functions. The suprapubic operation was accompanied with far more shock than the author had found following perineal prostatectomy.

Dr. Lewis Schooler of Des Moines, Iowa, read a paper in which he spoke of the symptoms, signs, diagnosis, prognosis, and palliative treatment of hypertrophy of the prostate. The palliative treatment was divided into (*a*) Massage; (*b*) Aspiration; (*c*) Catheterization; (*d*) Dilatation, and (*e*) Cystotomy. In considering all of the above methods, none were intended to be radical; none were calculated to remove the cause. All were intended, to partially, at least, restore functional activity, and to produce results sufficiently satisfactory to prevent the need of more radical procedures, and until within the last five years they were the best that the profession possessed. The dissatisfaction with them was clearly shown by the constant aim to discover something that would give better results. In a few cases they had served the purpose well, and in the future would be resorted to in very few select cases. But the better knowledge of the anatomy of the prostate gland and its pathology called for an advance in therapeutic resources that did something more than to secure relief with a constant menace to the life of patients through infection, as well as a method that did not require eternal vigilance, and a knowledge of the fact that the life of the individual depended upon the mechanics of artificial urination.

The Pathology and Etiology of Prostatic Hypertrophy and Suprapubic Drainage as a Method of Treatment.—Dr. A. C. Bernays of St. Louis, Mo., dealt with this phase of the subject. Suprapubic cystotomy was an operation which found its application in stone in the bladder, tumors, and growths, hypertrophy of the prostate, foreign bodies, exploration of the bladder, and drainage of the viscus. It was a recognized and successful method of treatment in all of these conditions. The technique varied with the object in view. Some ten years ago the speaker had the notion that suprapubic drainage would cure prostatic hypertrophy. He reasoned that by the drain he could give complete physiological and mechanical rest to the bladder; he could prevent the unrest due to the alternating filling and emptying of that viscus. He had hoped that the hypertrophied prostate under the influence of rest would undergo absorption and atrophy, and that a decrease in size, which might be permanent, would take place. In this latter hope he was doomed to disappointment. In all cases of hypertrophy of the prostate in which he made free permanent drainage for from three to ten weeks, the urine became normal in color, the cystitis was much improved, and in some cases entirely cured. He was convinced that as a radical cure of prostatic hypertrophy the suprapubic drainage was a failure. He spoke of hypertrophy of the prostate as a form of neoplasm or tumor. It was either a diffuse myomatous hypertrophy, or it was a localized formation of nodular myomata except in rare instances. Myoma could not be made to disappear by castration, either in men or in women, nor could it be made to do so by giving the parts in which the myomata were located physiological and mechanical rest by means of the suprapubic drainage. His training and feelings were so much opposed to operations in the dark that the Bottini and even the popular internal urethrotomy could receive no support from him.

Suprapubic Prostatectomy.—Dr. C. H. Mayo of Rochester Moore discussed this subject. Prostatic surgery had emerged from prospective obscurity. Statistics should only be considered in a general way as representing the developing stage of prostatic surgery. One-half of the enlarged prostates could be reached either from above or below equally well, one-fourth better from above, and one-fourth better from below, and a few would require a combined operation. The method of operation was influenced by the conditions of the gland and by other known and unknown accessory conditions. The lateral lobes were glandular and encapsulated, the middle might be glandular and encapsulated, or a muscular bar, or hypertrophy of mucous glands and bladder tissue. Of known conditions which influenced one's choice, the fleshy individual with thick perineum, long prostatic urethra, and high lying prostate was one for suprapubic or combined operation. Large dilated bladders were easily reached from above, and small, contracted bladders more easily from below. Those with stone present and enlarged prostate were best made from above. Of unknown conditions which influenced one's choice he had cases of symptomatic stone not found by search and emergency operations made in the country. These were the cases in which the suprapubic incision was the most satisfactory. Those with cystitis and old or acute secondary changes in the testes would often improve after castration. There was still a large class of prostatic sufferers in whom there were no symptoms of stone, little or no cystitis, and short perineal distance in which a perineal operation was unquestionably the better method. The ease of operation, perfect drainage, and earlier recovery in chosen cases no doubt justified this choice. The special retractors of Syms and Ferguson simplified the accessibility of the gland from below, and it was quite possible from present indications that this method would be developed into the operation of the future by making earlier diagnosis of conditions, and operating before the patients reached the stage of necessary suprapubic incision. Before suprapubic operation a hypodermic of morphine was given to reduce the amount of the anesthetic. Usually chloroform was indicated, but ether was preferred. The Trendelenburg position was employed with air inflation of bladder and finger enucleation of enlargements after incising the capsule. Suprapubic drainage should be established by closing the bladder over the tube by Witzel's method.

The Indications and Limitations for the Bottini Operation.—Dr. LOUIS E. SCHMIDT of Chicago read a paper with this title. After discussing at length the indications and limitations of this operation, he concludes that good results of the Bottini operation will depend (1) On the correct selection of cases; (2) On the proper technique of the operation and proper after-care; (3) The immediate correction of errors or mishaps.

How Shall We Treat Sepsis Following Labor and Abortion?—Dr. W. O. HENRY of Omaha, Nebraska, in a paper on this subject took the ground, first, that it was important to remember that sometimes malarial and other fevers followed closely upon abortion and labor, and all such cases should be carefully distinguished from true puerperal sepsis; but having once fully determined that infection has really occurred along the genital tract only one line of treatment was justifiable in the present state of our knowledge. Although he admitted the different varieties of infection, yet since it was both unsafe and impractical at the present time to wait for bacteriological examination, and since, further, the treatment he recommended was safe, practical, curative, and within the reach of every physician, he insisted upon its universal adoption. After giving somewhat elaborately the reasons for his belief, he summarized as follows: (1) Remove early with the finger, sharp curette, and flushing all debris, decidua, blood clots, and sloughing tissue, which may be infected, from the uterus and from all raw surfaces in the cervix, vagina, and vulva. (2) Dry all of these raw surfaces and freely apply to them 95-per-cent. carbolic acid, washing away the carbolic acid with plenty water. (3) Leave absolutely no gauze, drainage tubes, or packing of any kind in either the vagina or uterus. (4) Have simply sterilized a 2-per-cent. vaginal douche used twice a day thereafter. (5) Open the bowels freely with calomel, one-half grain every hour for four hours, then follow with Rochelle salts until sufficient action has occurred. (6) Give quinine, three grains every four hours, followed by tincture of chloride of iron, fifteen drops in water. (7) Give good nourishment with milk, eggs, and stimulants every four hours. (8) Let this be the routine early treatment, and hysterectomy will be rarely required. (9) When fixation of uterus occurs and infiltration takes place in Douglas's cul-de-sac or the broad ligaments, or when the tubes or ovaries fill with pus in acute cases, open promptly and drain through the vagina. (10) If multiple abscesses occur in the uterine wall or the walls become badly infected, or, if necessary to get perfect drainage for a badly infected pelvic cavity, remove the uterus and all else necessary by the vaginal route. The abdominal route is dangerous in all acute cases and is seldom if ever justifiable.

A New Method of Anchoring the Kidney was described by Dr. BYRON B. DAVIS of Omaha, Neb. This method can best be explained by giving a report of the only operation yet done by it. A. J., unmarried female, aged twenty-one years. Had frequent gastric crises, and a good deal of constant lumbar pain, on right side especially. Had lost twenty-five pounds in weight during the past year, and was very anxious for relief. On examination the right kidney was found freely movable, falling so low that the upper pole could be felt on bimanual examination. The left kidney was also somewhat movable. Patient entered hospital November 9, 1901, for operation on right side, which was done November 11. The incision extended from the lower rib to near the crest of the ilium, a hand's breadth to the right of the spinous processes of the vertebræ. The fatty capsule was reached just anterior to the outer border of the quadratus lumborum, and was opened and a large part of it trimmed away. The kidney was pushed into place by a cylindrical pad placed under the abdomen. When the kidney was well exposed, an incision was made through the proper capsule from one process below the upper pole to a point 2 cm. above the lower pole. This incision was placed vertically on the posterior surface near the convex border. The capsule was stripped loose from the kidney substance from a distance of three-fourths inch anteriorly and posteriorly to the incision of the capsule. From the upper and lower extremities of the vertical incision a perpendicular incision three-fourths inch long was made through the capsule, this giving two flaps of capsule three-fourths inch wide by about two and one-half inches long. Next, a strip the thickness of one's little finger of the other border of the quadratus lumborum muscle was split off from the remainder of the muscle, the fibers being separated by the handle of the scalpel. This separation extended from the muscular attachment to the twelfth rib downward for two and one-half inches, or the slit in the muscle was made as long as the length of the capsular flaps before described. Next, an artery forceps was passed through the slit in the muscle, made to grasp the free border of the posterior flap of the kidney capsule and then withdrawn, bringing the flap of the kidney capsule through the slit in the muscle. The two capsular flaps were next brought together over the bundle of muscular fibers thus isolated from the border of the quadratus lumborum, and stitched together with a running suture of fine chromic catgut, the needle being allowed to penetrate the muscular bundle at two or three places. The lumbar wound was next closed by tier sutures of catgut, the skin wound being closed with horsehair. Aside from a slight infection, the wound did well. Patient was allowed up on the twenty-second day. The kidney thus far was in place, and the patient relieved of her former symptoms, although it was too early to predict anything of the final result. This method was reported because it represented a new principle in treatment.

Intestinal Obstruction from Meckel's Diverticulum, with Recovery.—Dr. A. E. Halstead of Chicago reported a case and presented the following summary of all cases in the literature that were accessible to him. Total number of cases reviewed, seventy-two; males, forty-five; females, seventeen; sex noted in only sixty-two; result noted in sixty-five; deaths, forty-four; recoveries, twenty-one; percentage of mortality, 67.6; percentage of recovery, 32.4; cases operated upon, fifty-five; death in cases operated upon, twenty-seven; no operation in seventeen; percentage of death in cases operated, 49.0+; attachment or non-attachment of diverticulum or diverticular ligament, mentioned in sixty-six; point of attachment noted in forty-four; to mesentery in twenty-one; to umbilicus in fourteen; not determined in three; diverticulum attached, forty-seven; and diverticulum free, nineteen.

Grave Abdominal Injuries Without External Evidences of Traumatism.—Dr. R. Harvey Reed of Rock Springs, Wyoming, read a paper in which he discussed this subject. From reading the literature, together with his own experience, he was led to the conclusion that it was the surgeon's duty to make an exploratory incision in all cases where there was grave doubt as to the real nature of an injury, and particularly so when the constitutional symptoms pointed to a condition more serious than was indicated by either the subjective or objective symptoms, provided the physical condition of the patient was such as to warrant an operative procedure.

Dr. A. W. Abbott of Minneapolis, Minn., detailed a great many experiments on animals with a view to determining the immediate effects of intestinal exposure. From his experimental work, he concluded that in operations, where the intestines were exposed, the loss of water was unimportant, except in so far as it influenced the loss of heat and the drying of the surface; that the loss of heat was very important, as it temporarily placed the temperature of the intestines below the safety line of vital action, and secondarily the heat of the whole body below that which should be continuously maintained; that the drying of the peritoneum was so decided, that it must disturb to some extent the anatomical relations, and the resisting and recuperating power of that membrane; that the loss of heat and the drying process must suspend for an undetermined period some of the physiological functions of the peritoneum, and influence, to a degree as yet unknown, pathological conditions.

These conclusions the modern surgeon had reached clinically, in a general way, as shown by a short incision, protection pads, a minimum exposure of the peritoneum, and short-time operations. The writer believed that the exposure of the peritoneum should be the subject of a more critical study, and that this should be supplemented by extended experiments on the later effects, especially in their relation to peritonitis and adhesions.

Our Hospitals.—Dr. H. D. Niles of Salt Lake City, Utah, spoke on this subject. He said it was very evident to the minds of physicians familiar with the situation that the methods and management that had served hospitals so well when their purpose was limited to the care of the sick within their walls, would not suffice if the hospitals were to meet present needs and fulfill their possibilities as a great system of scientific institutions distributed throughout this country, where not only the favored few, but the whole profession, with all the sick intrusted to their care, might feel the results and participate in the benefits. So long as a hospital measured its own usefulness by the number of patients treated, the standing of each member of the staff would be estimated largely by the size of his personal following; and the commercial spirit would rule both the institution and the individual to the exclusion or great detriment of scientific work. If the profession was ever to secure a voice, it should formulate and adopt a business code that should not only meet the highest requirements of the ethics of the profession, but at the same time command the respect and win the confidence and support of the twentieth-century public. The object of the paper was to arouse, if possible, a more active interest in an institution that promised, with the aid of medical men, to become one of the most influential elements in the medical world—its labors, its literature, its thought, its discoveries, and its advances.

Surgery of Spina Bifida.—In a paper with this title Dr. Van Buren Knott of Sioux City, Iowa, discussed the varieties of spina bifida, the clinical features, diagnosis, prognosis, and treatment. After reporting four cases, he drew the following conclusions: (1) Owing to the distressing nature of the affection, the high mortality should not prevent attempts at surgical relief; (2) Meningoceles, meningomyeloceles, and syringomyeloceles may be considerably benefited by operation; (3) The improvement in function cannot with certainty be estimated before operation, and pronounced evidences of nervous disturbance are not a contraindication to excision; (4) Asepsis is absolutely essential, and although difficult to secure, may be maintained by exercising extreme care; (5) The plan of having the suture lines of the meninges and the overlying tissues on different planes will in the majority of instances prevent leakage of cerebrsopinal fluid; (6) The suggestion of Pearson to prevent the escape of this fluid during a prolonged operation by stuffing the canal with gauze is valuable; (7) Large bony defects may be effectually closed by muscle much easier than by osteoplastic methods; (8) It is not necessary to keep the child off its back during the healing of the wound, as is frequently advised; (9) Children with hydrocephalus accompanying spina bifida should not be subjected to operation.

Other papers were read as follows: "Two Cases of Cysts of the Broad Ligament Complicated with Myxoma," by Dr. Edward Hornibrook of Cherokee, Iowa; "Diffuse Sarcoma of the Uterus," by Dr. D. S. Fairchild of Clinton, Iowa; "New Operation for Wandering Kidney," by Dr. E. Wyllys Andrews of Chicago, Ill.; "The Operative Relief of Impaired Function of the Elbow-Joint Due to Faulty Reattachment of a Separated Internal Humeral Epicondyle," by Dr. G. G. Cottam of Rock Rapids, Iowa.

The following officers were elected for the ensuing year: *President*, Dr. James E. Moore, Minneapolis, Minn.; *First Vice-President*, Dr. J. R. Hollowbush, Rock Island, Ill.; *Second Vice-President*, Dr. W. W. Grant, Denver, Colorado; *Secretary-Treasurer*, Dr. George H. Simmons, Chicago.

St. Joseph, Mo., was selected as the place for holding the next annual meeting; time, December 29 and 30, 1902.

Osteomyelitis Following Measles.—Joel E. Goldthwait reports the case of a girl of six years, who ten days after the onset of measles had severe pain followed by swelling in the left leg. The swelling rapidly became fluctuating, and was opened freely, showing the whole upper half of the tibia denuded of periosteum. The left knee was swollen, and below the tubercle of the tibia there was a granulating wound two or three inches long with exposed bone. A few months later a radiograph showed an extensive osteomyelitic process with the whole upper half of the shaft of the tibia as a sequestrum. An attempt at repair with extensive formation of new bone was clearly shown. Later radiographs show almost complete replacement of the shaft of the tibia with a sequestrum between two and three inches long, lying obliquely in the upper part of the bone. As to prognosis, while the function of the knee bone will be impaired, it will not probably be a very serious limitation, and the strength of the leg, aside from the shortening, should not be much below normal.—*Annals of Gynecology and Pediatry.*

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 19, 1901.

Hermann Knapp, M.D., Vice-President, in the Chair.

Remarks on the British Congress on Tuberculosis and the Prevention of Tuberculosis.—Dr. E. G. Janeway made a few remarks on this subject in response to the invitation of the chairman. The congress, he said, had been a marked success, and owing to the presence of representative men from various countries it had partaken of an international character. Formal addresses had been presented by the representatives of different nations, Dr. Osler speaking for America. Dr. Robert Koch had insisted that all the facts pointed to the sputum of tuberculous individuals as the main source of infection. He spoke also of the proper hygiene of such persons, and on what had been accomplished by treatment in sanatoria. He made the statement that there were 226,000 persons in Germany over fifteen years of age, so far gone from consumption that hospital treatment was necessary, yet only 2[illegible] could be accommodated in the sanatoria. Of this number experience showed that about 4,000 would lose the bacilli from their sputa. Koch stated most positively his disbelief in the identity of human and bovine tuberculosis. Among the reasons given for this opinion was that experiments on cattle had shown that bacilli originating from human tuberculosis would not induce tuberculosis when injected into or fed to cattle. Moreover, as milk and butter contained bovine tubercle bacilli to a considerable degree, there should be a much greater amount of primary intestinal tuberculosis if human beings were infected from this source. Koch was of the opinion that the proportion of cases of primary intestinal tuberculosis was hardly greater than would be accounted for by hereditary transmission. Dr. Janeway cited a very suggestive case that he had encountered. A group of three children in one family, two children in the family of a neighbor, and one child in another neighbor's family, all developed tubercular glands of the neck. The cook in the first family said that she had noticed blood in the milk used. Dr. Janeway asked the State Board of Health to investigate, but before this could be done the cow from which the milk had been obtained died. It was significant that all of the children had been fed on the milk from this cow. Careful search had failed to show any other source of infection in these families. Dr. Janeway said that he could not believe that milk from diseased cattle would furnish the best food for either children or adults. A remarkable fact brought out at the congress was that the mortality in Great Britain from tuberculosis had diminished from 1851 to 1901 50 per cent; in other words, that only about one-half as many died from this disease now as compared with fifty years ago. The opinion seemed to prevail that tuberculin should only be employed in afebrile cases. Dr. Janeway then spoke of the urgent need for greater accommodations in sanatoria for poor consumptives. For the boroughs of Manhattan and The Bronx he estimated that 5,000 succumb to tuberculosis each year, and hence this number, plus the number who recovered, would represent the total number for whom accommodations might be required. It should not be forgotten that even persons of slender means sometimes went into the country and lived on farms away from medical supervision, and so became a source of danger to those around them. The speaker said that the habit of expectorating into the handkerchief was a most unsanitary one; he looked upon the pocket handkerchief almost without an equal as a disseminator of disease. Another point of great practical importance, which should not be overlooked, was that it was not proper or safe to pronounce the sputa of a person harmless simply because one examination had shown an absence of tubercle bacilli.

Tuberculin Treatment.—Dr. E. L. Trudeau, being unable to be present, sent a letter. He said that he had used tuberculin for the past ten years, both as an aid to diagnosis and as a specific method of treatment. As an aid to diagnosis he had applied it mostly in suspected cases of incipient tuberculosis of the lungs, and in most instances it had enabled him to make a positive diagnosis before he could have done so by means of the rational or physical signs. He had never known it to have a bad effect on the tuberculous process. It should not be used when there was much fever, because the results obtained were unsatisfactory, and also because it had seemed to him that it might be dangerous by the hyperæmia which it induced, causing an intensification of the secondary process. The method should not be used indiscriminately, and, indeed, was required only in comparatively few cases. He had also used tuberculin therapeutically in tuberculosis. In an apyretic case in which there was no reason to suspect secondary infection, if given in small doses so as not to produce a rise of temperature, it was free from danger, and the results he had obtained with it had been encouraging. The susceptibility of the patient to tuberculin varied greatly in different individuals. After the patient had become tolerant to quite large doses, the treatment should be discontinued for several months. If then it was found that susceptibility were again present, the use of the tuberculin should be once more begun. Dr. Trudeau said he did not feel able as yet to speak authoritatively regarding the relative value of the different preparations of tuberculin. The production of a marked degree of toxin immunity did not necessarily mean marked bacterial immunity. This treatment was limited to cases which were likely to recover under ordinary climatic and hygienic treatment, and the latter, in his opinion, was the best means at our command for the arrest and cure of tuberculosis. The letter closed with an earnest appeal for more sanatoria, properly endowed, so as to place them within the reach of the poor. Dr. Trudeau hoped that his sanitarium would be endowed so that the good work which he had initiated and had carried on there so successfully might be continued after he had gone.

Difference Between Bovine and Human Tuberculosis.—Dr. Theobald Smith read the introductory paper on this subject. That bovine and human tubercle bacilli were not identical, he said, had occurred to him about ten years ago, while watching the effect of these bacilli on guinea-pigs. When in 1894 he had isolated and studied comparatively a bovine culture and one domiciled in a tuberculous man, the great difference in the results obtained had impressed him with the belief that there was a great difference between these bacilli. In 1897 a sufficient number of pure cultures had been isolated to enable him to test bovine and human bacilli on cattle. The outcome of these experiments had justified the claim that there was a distinctly human and a bovine tubercle bacillus. Cases of direct inoculation could not decide the question because the conditions were thereby changed. He raised the question as to what it was that prevented the entrance of germs of tuberculosis through the mucous membranes in animals susceptible to inoculation. At one time he had made notes of eighty-eight autopsies on cases of bovine tuberculosis, and had found in eighty-five of them lesions of the thoracic organs. Of this number, forty-one showed disintegrating foci and had been discharging tubercle bacilli. This fact should be borne in mind by physicians having many dairymen under their care. Dr. Smith declared that bovine tubercle bacilli possessed definite traits or features which served to distinguish them from the great majority of cultures isolated from the human subject. They differed not only morphologically, but in virulence from human tubercle bacilli. If in any case of spontaneous tuberculosis one should find bacilli agreeing morphologically and in virulence with those of the bovine race, one must concede that the case was of bovine origin; but even then one would be confronted with the question as to why there were so few infections from this source in view of the many opportunities for such infection. In children the type of the disease approximated that found in cattle, but this similarity must not be construed as pointing to an identical etiology. He believed that a few bacilli were harmless, but that the flooding of the intestinal tract with numerous bacilli was dangerous. This view he had first announced in 1898. At that time he had also raised the question as to the possibility of the bovine tubercle bacillus entering the digestive tract of the human subject, and in its passage through the system undergoing such a modification that on appearing in the sputum it would present the general characters of the human tubercle bacillus. It was probably that there was an initial resistance of the human body to the bovine tubercle bacillus, and this explained the comparative harmlessness of a few such bacilli. On the whole, the student of comparative etiology was inclined to believe that ordinarily the pathogenic action of a bacterium was confined to a certain large group or race, and only sporadically exerted its special action outside of those limits. The transmission of glanders from the horse to man was an established fact, but when one took into consideration the large number of cases of glanders occurring annually in horses, and the large number of human beings brought in intimate contact with these animals, the number of cases of glanders occurring in the human subject sunk into insignificance. We had no right to assume the indiscriminate transfer of bovine tubercle bacilli to man, and hence we should not except the broad, sweeping statement made by Koch. Undoubtedly, exceptions might occur; it was our duty to ascertain how numerous were these exceptions. The conclusions which might be drawn provisionally from the foregoing considerations were: (1) That there was no evidence that bovine tubercle bacilli might indiscriminately infect the human subject, and (2) That there was some evidence that bovine bacilli had been isolated from human beings, and that the successful transfer was uncommon and depended upon certain conditions requiring further careful research.

Dr. H. M. Biggs said that it seemed to him that Koch's position involved two considerations, viz., (1) That bovine and human tuberculosis was distinctly different, and (2) That we might ignore, from the human sanitary point of view, the production of tuberculosis by infection from cattle. There were strong grounds for the belief that the bovine and human tubercle bacilli were of two different types, and that the bovine bacillus infected the human subject with difficulty. He had no doubt that the proportion of cases of tuberculosis in the human subject of bovine origin was considerable. The statistics of the Board of Health of New York City showed that in certain crowded sections of the city from 8 to 10 per cent. of the population was infected with tuberculosis, while in other and more sanitary districts only one-fourth to one-half of 1 per cent. was so afflicted. It was reasonable to believe that in the poorest districts one would find the most marked effect from the use of poor and unwholesome milk. The statistics of Great Britain and of this country regarding intestinal tuberculosis differed very widely. All authorities in this country agreed that cases of primary intestinal tuberculosis were of rare occurrence here; they represented about 1 per cent. in this city as contrasted with about 10 per cent. in Great Britain. Cases of abdominal tuberculosis were likewise rare in Germany. It was evident, therefore, that the conditions of infection in Great Britain must be peculiar, though as yet just what they were was not known. The speaker said that for the last few years he had come to feel that there was little reason for restricting tuberculosis in animals, so far as regards the effect upon human beings. Undoubtedly, the restriction of bovine tuberculosis was an important agricultural problem; but from the point of view of the public health it did not seem to him of special importance except perhaps as regards disease of the udder. At one time, Rokitansky had injected subcutaneously a number of bovine bacilli into eight or ten persons suffering from cancer. Some months later, these persons having died, examination failed to show any tuberculous lesions either at the site of the injection or in the neighboring lymphatics, or in the internal organs. Of course, such experiments were only suggestive, for we did not know but the same result would follow the subcutaneous injection of human tubercle bacilli.

Dr. W. H. Park said that he had understood Dr. Biggs to say that he did not believe bovine tuberculosis was a source of danger to human beings. If this were so, he did not quite understand Dr. Biggs' allusion to disease of the udder. Possibly this statement had reference only to the undesirability of adding filth to the milk. The speaker referred to certain racial characteristics of bacteria, and reported some experiments that he had recently made, going to show that human bacilli did not infect calves under ordinary circumstances. He had taken four calves and fed them for two weeks with from one to two ounces daily of sputum rich in tubercle bacilli obtained from many consumptives. The animals had been tested first with tuberculin. The experiments had been carried on for five months, and the animals recently killed failed to show the presence of tuberculosis.

Origination of Tuberculosis from Cow's Milk.—Dr. A. Jacobi opened the discussion on this topic. After quoting freely from the literature, he said that it seemed to be clear that the milk of cows reacting to tuberculin, but presenting no lesion of this disease, contained no tubercle bacilli. Apparently the cases of infection with tuberculosis from the milk were not very numerous, but a number of well-authenticated ones had nevertheless been reported. He was of the opinion that the absorption of tubercle bacilli might take place even though the intestinal mucous membrane of the child was normal. One reason for this belief was the frequency of primary tuberculosis of the peritoneum in children. It was almost always localized, and usually preceded and did not follow pulmonary or general tuberculosis. Tuberculosis of the peritoneum could originate only in one of two ways, *i. e.* either through the blood, in which case there would be a more disseminated type of the disease, or else through the intestine. The restriction of bovine tuberculosis seemed to him of vital moment—a question which was a great deal more than an agricultural or economic problem.

Dr. W. P. Northrup said that in a large experience he had never seen clinically a case which seemed to him to give evidence that the earliest infection with tuberculosis had been in the mesentery. He had noted carefully the autopsy findings in 125 cases of tuberculosis in children. In thirteen of these cases the only tubercular process in the entire body was in the lymph nodes around the trachea, and in three only was the oldest process apparently in the mesenteric lymph nodes. There were many experiments on record to show that bacilli could pass through the intestinal mucous membrane without any lesion of this membrane discoverable by the microscope. According to his experience, tuberculous infection in children usually began in the lymph nodes about the neck and trachea, then involved the lungs, then the liver and spleen, then the peritoneum, then the kidneys, and lastly the brain. He could not, therefore, accept what had been said by Dr. Jacobi about peritoneal tuberculosis as bearing upon the question of primary intestinal tuberculosis.

Dr. David Bovaird, Jr., said that in a later series of 125 cases of tuberculosis coming to autopsy at the New York Foundling Hospital there had been just two in which the infection had appeared to be primary in the intestine. Adding the 125 cases at that institution just quoted by Dr. Northrup, there were 250 cases with only five in which the primary infection had apparently been in the intestine. Almost all the reported cases of death from tabes mesenterica came from England, and although two emi-

[illegible] pathologists in London hospitals maintained that [illegible] was unknown; [illegible] the statistics of London made it appear that there were upward of one thousand deaths a year from this disease. These discrepancies made these statistics of questionable value. It seemed to him that the ground taken by Dr. [illegible] was perfectly sound.

Owing to the lateness of the hour, the discussion of "The Need of Sanatoria for Tuberculosis" was postponed to the next meeting.

Annual Election.—The annual election resulted as follows: *Vice-President*, Dr. A. P. [illegible]; *Member of Committee on Admission*, Dr. W. L. Carr; *Member of Committee on Library*, Dr. W. B. James.

NEW YORK ACADEMY OF MEDICINE

SECTION ON MEDICINE

Stated Meeting, December 17, 1901

E. Franklin Smith, M.D., Chairman.

Antistreptococcus Serum in Pernicious Anæmia.—Dr. James J. Walsh read this paper. He said that half a century ago pernicious anæmia had been called idiopathic anæmia because no one knew what it was, and that even to this day not very much was known about it. It simulated cancer and the severe secondary anæmias, such as resulted from hemorrhage or from the infection of the anchylostoma duodenale. The etiology of pernicious anæmia had been shrouded in mystery, but it was thought by most observers to be more common now than formerly. Three years ago Dr. William Hunter of London had propounded the theory that all patients suffering from pernicious anæmia had carious teeth, and that the latter caused a septic gastritis with atrophy of the hydrochloric acid cells. He thought that it was caused by a gangrenous bacillus of the teeth as well as by other septic or pus-producing organisms. In treating such cases Dr. Hunter had used antistreptococcus serum together with antiseptic mouth washes. Undoubtedly arsenic did good in these cases, for formally cases of pernicious anæmia ended fatally in about six months, whereas at the present day they lived from one to two years. Osler stated that upon examination of cases of pernicious anæmia at his clinic no specific germs had been found in the teeth. Dr. Walsh said that he had had a case of pernicious anæmia last summer, with no carious teeth. The anæmia had begun after severe vomiting, lasting for several months. This fact suggested that possibly the affection was of the nature of a septic gastritis as Dr. Hunter had suggested. Arsenic was given, together with nux vomica, with slight improvement, but the patient had occasional attacks of vomiting. Then six injections of the antistreptococcus serum, obtained from the board of health, had been made in about as many days, 5 c.c. being used at each injection. Four injections were followed by a local reaction, and two injections gave a general urticaria, but they did not affect the progress of the disease. The history of cases in which the antistreptococcus serum had been used was decidedly disappointing, and evidently Dr. Hunter's conclusions were not borne out by clinical experience.

Dr. **James N. West** said that while he had had no experience with antistreptococcus serum in pernicious anæmia, he had used it in surgical cases, and failure had resulted. He thought that its use, even in this field, would have to be given up.

The Genesis of Epilepsy Clinically Considered.—Dr. **Louise G. Robinovitch** read this paper in part. She said that epilepsy was ultimately connected with alcoholism, and while one generation might not show it, it could be traced as far back as the grandparents. The acute infectious diseases occurring in the mother during pregnancy might cause epilepsy in the child. The excessive use of alcohol had been known to cause epilepsy in the children. Out of 14[illegible] cases of epilepsy treated in a Paris clinic, twenty had alcoholic parents.

Dr. **W. C. Hollopeter** of Philadelphia said that he agreed with the writer of the paper in that alcoholism was a cause of epilepsy. In one of his own cases an alcoholic subject had had five children. One of these children would have a convulsion after some slight gastro-intestinal disturbance, while another child would have one after a fright.

Dr. **J. Finley Bell** of Englewood, N. J., mentioned the case of a family of seven children, every one of them of dull intellect. He had accounted for this by the fact that the father was an inebriate. Dr. Bell suggested that malarial poison was possibly a cause of epilepsy, and cited the case of a young girl who had had malaria with the rest of the family when but four years old; she had developed epilepsy later, and as her family history was absolutely negative in other respects, he had attributed the epilepsy to the malaria.

Dr. **H. W. Berg** considered epilepsy as a chronic eclampsia. He gave the history of a college youth of twenty who had had an attack of epilepsy after eating some veal late at night. He had not suffered from an attack since two years of age. Dr. Berg said that he thought three pints of wine a day not sufficient to cause ill effects.

Dr. **Robinovitch** closed the discussion. She was of the opinion that three pints of wine per day was too large a quantity, at least for a Frenchman. Both clinical observation and microscopical study showed that the changes and degenerations in the nerves were similar in alcoholism and epilepsy.

The Etiology and Pathology of Cirrhosis of the Liver.—Dr. **James K. Crook** presented this paper. He classified cirrhosis under three forms, viz., the venous, hypertrophic, and biliary. The newly formed tissue might never lead to contraction of the organ, but there might remain only an increased proliferation of the connective-tissue cells. The causes of cirrhosis were divided into predisposing and exciting. Age and sex were very important as predisposing causes. Out of 4,000 cases of deaths taken from the records of the Board of Health during the ten years between 1889-1899, nine occurred under one year of age, and all were males; eleven occurred at five years of age or under, eleven at ten years of age, nine at fifteen years of age; five hundred at twenty-five years of age, and one thousand odd between twenty-five and thirty-five. Nationality was also important, the Irish leading, and the Germans being a close second. Among the exciting causes, alcohol took the lead in the form of whiskey, gin, and brandy; but beer would also produce it, as was seen in Germany. Active exercise tended to oxidize the alcohol and thus retard its development. Taking alcohol with meals did not lead to cirrhosis. Syphilis was also an exciting cause, as was also the malarial poison, though Osler said he had not seen a case of cirrhosis caused by malaria in the last nine years. Typhoid fever, as well as some of the acute infectious diseases, might produce cirrhosis. Eating highly seasoned foods, spices, etc., as seen in India, predisposed to cirrhosis of the liver. Dr. Crook spoke of the important part played by the mineral poisons, such as mercury, lead, and arsenic, in causing cirrhosis. Tuberculosis, cardiac disease, diabetes, and fright sometimes gave rise to a secondary cirrhosis.

Cirrhosis of the Liver in Children.—Dr. W. C. **Hollopeter** of Philadelphia read this paper, which treated of the etiology and diagnosis of cirrhosis. This disease was analogous in some respects to arteriosclerosis, and was generally the result of some secondary trouble. Oftentimes adult age was reached before the affection was recognized. Septic jaundice was usually due to the enlargement of the bile duct, and this condition was often accompanied by some elevation of temperature. If the condition persisted it would lead to an acute fibrosis of the liver.

Cirrhosis in children was not a rare disease as was formerly supposed. Even as late as ten years ago, it had been considered one of the rarest diseases in children. Dr. Hatfield had collected sixty-three cases of cirrhosis in children. The so-called interstitial hepatiti was usually the result of syphilis, but alcohol was the most frequent single cause. The fact was shown in the histories of one-sixth of all the cases reported. Irregular feeding, bad hygiene and the use of aromatic wines, such as the essence of peppermint, gin, etc., were frequent causes of this disease in children. The acute infectious diseases also played an important part. One case, that of a boy, was cited in which coffee had been the exciting cause. Dr. Hollopeter said that the atrophic and hypertrophic forms could not be clearly differentiated in children. Dilation of some of the superficial veins afforded some aid. The veins of the nose, face and ear were often enlarged, as well as those of the abdomen, showing that venous embarrassment was present. The spleen was almost always enlarged in these cases, and this was associated with other diseases of the liver. Gastro intestinal disturbances were very common in cirrhosis of the liver in children.

The Treatment of Cirrhosis of the Liver.—Dr. George M. Converse presented this paper. He said that much could be done by preventing the formation of cirrhotic tissue. He spoke of the formation and exudation of the toxines in this disease, and their effect upon the liver cells and on the gastro-intestinal mucous membrane. Alcohol seemed to be the chief causative agent. Milk was the ideal food in cirrhosis of the liver, as it caused the least irritation to the cells lining the gastro-intestinal tract. It should be continued until all signs of gastric irritation had subsided. This might be in a few weeks, but he had kept cases on a milk diet for from two to four months. Washing the mouth out with vichy would often prevent the disagreeable effect of the milk. It was important to consider the individual case and not treat all alike. Hepatic extracts had been suggested and tried with some degree of success. Diuresis and catharsis were necessary at times.

Dr. Berg said that he did not remember to have seen a case of the atrophic form of cirrhosis in a child, but that hypertrophic cirrhosis was quite common after scarlatina and other acute infectious diseases. He would not classify atrophic and hypertrophic forms of cirrhosis, together, any more than he would classify the large, white kidney with the small contracted kidney. Atrophic cirrhosis should never be diagnosed until paracentesis had been performed. He recalled a case that had simulated the atrophic form, but after paracentesis had been done, a cancer of the stomach was found to be the cause of the ascites.

Dr. Meyer said about fourteen years ago it had been the custom to remove the ascitic fluid very slowly by means of a fine needle and trocar, so slowly that it would take three or four days to remove the fluid. This method was not generally followed by reappearance of the fluid. The disadvantages were the loss of sleep and the local irritation of skin.

Dr. James J. Walsh said that he thought the fluid should be evacuated as soon as possible, and when any systemic disturbance presented itself. He called the attention of the section to Professor Vaughan's statement that mineral poisons were the cause of cirrhosis, and that aluminum would cause it.

Dr. James K. Crook said that the name cirrhosis was a misnomer; it did not describe the true condition of the organ. He did not agree with Dr. Berg that cirrhosis was either atrophic or hypertrophic; all forms of cirrhosis at the very beginning were hypertrophic. The name "chronic interstitial hepatitis" was a better term, for it described the exact condition of the liver.

Dr. Hollopeter remarked that his attention had been called to the frequency of cirrhosis of the liver in children some ten years ago, while attending a clinic in London.

Dr. George M. Converse closed the discussion by directing attention to what he described as alcoholic hypertrophic cirrhosis, which differed from the common hypertrophic and atrophic cirrhosis in the chemical reactions of the liver cells.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, December 16, 1901.

PARKER SYMS, M.D., PRESIDENT.

Double Fibroid of the Uterus.—Dr. Frederick Holme Wiggin presented this interesting specimen, together with the history of the case. Another specimen of especial interest was one with carcinoma of the cervix uteri with a large fibroid of the body of the uterus.

Decidua Maligna.—Dr. Wiggin also presented this specimen with the following history: The patient had missed three menstrual periods, and had then been taken with a severe hemorrhage, passing clots and other substances resembling hydatidiform moles. She complained of severe pains in the thighs and legs, increased on extension of the lower extremities. Bimanual examination showed the uterus to be as large as an orange. The patient was put on the table for a curettage. During the curetting, such severe hemorrhage occurred that the ordinary methods of controlling it had no effect. As the patient was in danger of bleeding to death, it was decided to perform a laparotomy and remove the uterus. After the uterine arteries were clamped the hemorrhage was controlled. The uterus was removed, and the diagnosis of decidua malignum was made. In such cases, death generally takes place from metastasis in the lungs. Dr. Chas. E. Quimby had been called in and had made a thorough examination of the lungs, but found that they were not involved.

Dr. F. M. Jefferies exhibited slides taken from the specimen, and said that he was not able to make a positive diagnosis, but he felt reasonably sure that it was an early stage of decidua malignum. He had had a similar specimen within the last month in which he had been able to make a positive diagnosis. The cincilate (deciduous) elements seen in the uterine wall were hardly deep enough in the uterine tissues to be positive.

Dr. C. H. Schultze had seen the specimen and agreed as to the diagnosis.

Symposium on Tuberculosis.—This comprised the following papers:

The Present Status of the Use of Tuberculin and of the Products Obtained Directly or Indirectly from the Tubercular Bacillus in Pulmonary Tuberculosis.—Dr. E. A. de Schweinitz, Chief of the Biochemic Laboratory at Washington, D. C., was the author of this paper, but being unavoidably absent, it was read by Dr. Chas. E. Denison. The writer said that in preparing tuberculin it was important to have a standard, and the one adopted was a sterilized glycerin solution of a culture of the tubercle bacillus. The culture not only contained the germs, but their products. In preparing the older forms of tuberculin such a high temperature had been used that certain chemical changes had taken place in the toxins. In quoting from Otis, that out of 1,000 cases a comparatively small percentage reacted, Dr. de Schweinitz said that it certainly shook one's confidence in tuberculin. The tuberculin used in the United States experimentally upon swine, dogs, and horses had failed to give reactions. Recent publications, endeavoring to show the relationship between bovine and human tuberculoses were very interesting. Of course, it was impracticable to inoculate man, so man's first cousins, the monkeys, had been inoculated with human and bovine tuberculoses. A ring-tailed monkey and a baboon had been inoculated with a culture of human tubercle bacilli. The baboon died in six weeks, and upon necropsy [illegible] tubercular [illegible] The ring-tailed [illegible] had also been [illegible] with the same culture as the [illegible] and had died two weeks [illegible] showing that the [illegible] had greater [illegible] powers than the [illegible] The [illegible] had been kept to [illegible] and the object of the experiments had been to produce an artificial [illegible] along the line followed at the present time in the manufacture of diphtheria antitoxin. In general, [illegible] was of the opinion that tuberculin should be used most carefully for diagnostic purposes, because certain toxic products of the bacilli might cause deleterious results.

The Early Diagnosis of Pulmonary Tuberculosis with Exhibition of X ray Pictures of Diseased Lungs.—Dr J. Edward Stubbert of Liberty, N. Y., read this paper. Its early diagnosis was important and made in what might be called the pre-bacillary stage, but it was not always possible to do this. Physical signs were very indefinite and every known method would often be required before the diagnosis could be positively known. When the patient went to the physician for a diagnosis he should not be deceived as to his condition. Out of a number of cases of incipient phthisis at Liberty, N. Y., 15 per cent. had apparently been cured, and 63 per cent. had been enabled to return to their homes as useful citizens. Race, traumatism, catarrh of the upper air passages and with gradual loss of weight were important factors in the early stages. Slight hacking cough, with or without expectoration, slight rise of temperature and deranged digestion were also important symptoms. Dr. Stubbert said that he had seen many cases that had had a small hemorrhage—one to two ounces—and had given no physical signs whatever until weeks afterward. Some of the early important physical signs were a flattening of the clavicles; loss of expansion on the affected side, more easily seen posteriorly than anteriorly, and restriction of the motion of the diaphragm on the affected side. Very early cases, as a rule, did not give rapid respiration, but in most instances a high-pitched note and prolonged expiration were present and were exceedingly suspicious. Râles at this stage were seldom heard. The absence of tubercle bacilli in the sputum was not a final diagnostic point. In using the tuberculin test, Dr. Stubbert said that experience had shown that there was a reaction in syphilitic cases. It had been said that anæmia was present in the early stage of tuberculosis, but of forty-two cases at Liberty no such change in the blood had been noted at this stage. It was the disease that caused the anæmia, not anæmia that caused the disease. In advanced cases with cavities, some leukocytosis was present. As the cavity dried up the leukocytosis disappeared. The *x*-ray was of assistance in making the early diagnosis. It was better to use the fluoroscope, without a screen, and to apply it to the bare chest, beginning at the apex and working down toward the base of the lung. In about 50 per cent. of normal chests the right apex appeared less clear than the left. A slight haze was often seen whenever the pleura was affected. If the patient took a long breath the normal side became clearer, while the diseased side remained the same. A practised eye could detect an incipient focus. One of the pathognomonic signs in incipient cases was the more or less restricted motion of the diaphragm on the affected side. "Spotted Lung" was a term that had come into use since the *x*-rays had been employed for diagnosis. They gave a mottled appearance to the diseased area. Dr. Stubbert's paper was illustrated by lantern slides. These included pictures of the normal and of the diseased chest, "spotted lung," lungs with cavities and with areas of consolidation, pleurisy with effusion and hyperæmia of the other lung.

Demonstration on the Cadaver of the Surgical Anatomy of the Lung.—Dr. Irving S. Haynes showed a case of long-standing empyema and drew attention to the space between the lower border of the lung and the lower angle of the reflected pleura. This space he called the costophrenic sinus. The depth of this space in the specimen exhibited was about 2 to 2½ inches. In health this space did not exist because normally the two surfaces of the pleura were in contact. Pathological conditions, such as pleurisy with effusion, would change this normal relation. Dr. Haynes also pointed out the relations of the spine to the left pleura. Speaking of the anatomy of the apex of the lung, he said that the pleura rose up into the neck and to a higher level than the clavicle forming the "pleural dome." It was one half to three-quarters of an inch above the first rib or clavicle. Textbooks on physical diagnosis states that the pleura rose much higher than this. This was to be explained by the fact that the resonance was transmitted to a higher point than the pleura. This region of the lung not being able to expand as much as other portions was very badly ventilated while it was anatomically possible to reach the right bronchus posteriorly, and no surgeon was likely to undertake such a rash procedure. After separating the pleura from the spinal column, the right bronchus and azygos vein would be exposed at a depth of about four inches, and when that point had been reached, the operation had practically just begun, for the bronchus had to be opened.

Surgical Procedures for Pulmonary Tuberculosis.—Dr. William G. Le Boutillier read a paper with this title. He said that the bright hopes once entertained by some that surgery might offer a speedy and sure operative cure for tuberculosis of the lungs, and might perhaps revolutionize their treatment, had thus far utterly failed. But surgery had something to offer of value at least in the way of palliation for such cases as empyæma, pleurisy, osteitis of the ribs, pyopneumothorax, and pneumothorax. The great obstacles to be surmounted in surgery of the lungs were operative and diagnostic. Surgical procedure had been resorted to for the removal of the diseased area, while local treatment by drugs, such as iodine, had long ago been abandoned. Nitrogen gas had been introduced into the pleural cavity with the idea of partly holding the diseased lung at rest. This method had practically no dangers connected with it, but it was still on trial. Other methods, which allowed cicatrization to take place, were unsatisfactory. Aspirations of cavities were not altogether satisfactory, being often inefficient. Satisfactory results had been obtained in the removal of the cavity when a large area had been removed. The operation should not be undertaken unless adhesion were present. Where there were cavities, nitrogen gas was useless, unless adhesion were numerous. In empyæma an early incision should be tried. When pneumothorax occurred, the chest should be opened and the lung sewed up. When suppuration developed in the thorax, an operation should always be done.

The Treatment of Pulmonary Tuberculosis.—Dr. Charles E. Quimby read this paper. He said that for those patients who were willing to sacrifice everything, the climatic treatment was the most desirable. The systemic nutrition was a matter of great importance, as it was a natural defense, so to speak, yet it received altogether too little attention in the early stages. The diet should be made as attractive as possible; the patient should live high, and, above all, the use of alcohol should be insisted upon. Stimulation was of the utmost importance. Aromatic bitters, such as gentian, together with alteratives, were valuable. Mercury and arsenic had a very powerful influence on metabolism. Another important point was to influence the pulmonary circulation by means of hydrotherapy or by dry vigorous rubbing of the skin. Even in pleurisy with effusion it aided the absorption of the fluid. It was perfectly possible to remove the exudate by mechanical means, while it could not be effected by climatic treatment alone. No treatment was complete that ignored this mechanical method. Inhalations seemed to have a direct effect upon the exudate. Antiseptics would not arrest it, but they tended to diminish it. Cloths wet with formalin, and placed near the patient's bed at night, did some good. As intestinal toxæmia was due to a sluggish state of the colon, such cases should be flushed out.

Dr. **William G. Schauffler** of Lakewood, N. J., opened the discussion. He said that the papers had been both interesting and scientific. The great problem confronting us was what could we do as physicians with the everyday cases. The rich we could send away, but the poor we always had with us. If the patient were sent away for the climatic treatment, a speedy recovery should not be promised. One could not rely upon medicine and climate alone, but must adapt the treatment to the individual case.

Dr. **H. P. Loomis** said that he did not entirely agree with Dr. Stubbert as to the diagnostic value of the x-rays. Early cases of incipient tuberculosis at the apex were very hard to make out because the shadows were numerous. As to the tuberculin test, he had injected ten or fifteen cases in Bellevue Hospital that were advanced in the disease, and they had given no reaction. He thought that one of the early signs was the presence of localized râles behind and under the scapula, the arm being drawn forward. As an examiner for the Adirondack Sanitarium, the question of prognosis became to him very important. He was of the opinion that when the digestion was bad, the case was bad. A rapid heart action —110–120 beats per minute—was a bad sign. Loss of flesh was also unfavorable. Heredity had very little effect upon the prognosis. The personal element was very important.

Dr. **S. A. Knopf** thought that diminished blood pressure was an early diagnostic point. He had had a very sad experience many years ago in using tuberculin, and had not cared to employ it since. He favored what he called the sanatorium treatment at home.

Healing of Gall-Bladder Wounds and Treatment of Defects in the Same by Transplantation of the Mesentery.—Enderlen and Justi have undertaken experimental research with respect to the healing of wounds of the gall-bladder, and the possibility of remedying defects in the same due to traumatism, by transplantation of the mesentery. For the observation of the natural healing of gall-bladder wounds, rabbits were used. In the transplantation experiments, dogs were employed, because in rabbits and cats the mesentery is too delicate in structure to be of service for this purpose. Wounds of the gall-bladder heal with complete regeneration of the mucous membrane. Abundant necrosis and insufficient drainage retard the healing process. The newly formed epithelium is at first of the lower varieties of epithelial cells. Later such are changed into cylindrical epithelium. The regeneration of the muscular coat is of small extent. The epithelium is rarely regenerated in the sulci. The transplanted mesentery is entirely able to repair the defects in the wall of the gall-bladder. In the transplanted mesentery the connective tissue proliferates. Subsequently such undergoes contraction. The epithelial layer, which very soon forms upon the internal surface of the transplanted mesentery, is raised into folds or reduplications, covered internally by the newly formed mucous membrane. The original defect is remedied in consequence of the shriveling of the mesentery and the contraction of the muscular coat of the gall-bladder. Practically, transplantation of the mesentery is seldom required.—*Deutsche Zeitschrift für Chirurgie.*

Diphtheria and croup	205	61
Scarlet fever	229	16
Smallpox	19	4
Chickenpox	34	..
Tuberculosis	209	146
Typhoid fever	29	14
Cerebrospinal meningitis	..	2

Functional Kidney Examinations in the Diagnosis of Surgical Kidney and Abdominal Lesions.—Leopold Casper reports successful results obtained in the differentiation of various surgical kidney and abdominal lesions by estimations of the functional activity of either kidney. This method consists in the employment of ureteral catheterization and the determination of the nitrogen and sugar (produced by phloridzin inoculation), and the freezing point of the urine thus obtained. In this manner it is possible to determine the amount of work that each kidney is performing. By this method the author examined nine cases. The first case showed symptoms of renal colic on the right side. Subsequently several stones were passed and the symptoms disappeared. Shortly after, signs of renal colic on the left side appeared, and it was thought that this side was also affected; but examination of the urine from the left kidney proved that it was normal. Operation showed that the right kidney only was affected. In another case the diagnosis lay between a tumor of the right kidney and appendicitis. The examination of the urine from the right kidney showed that its functional activity was normal, and the operation confirmed the diagnosis of appendicitis thus made. In the last case reported, it was impossible to tell whether the patient was suffering from biliary or renal colic, but by the employment of this method a diagnosis of biliary colic was made, and subsequent events proved this diagnosis to be correct. These cases show the value of this method of diagnosis. It is not recommended that it should be used to the exclusion of other methods, but simply employed in obscure cases where these other methods fail.

A Case of Primary Tuberculosis of the Parotid Gland.—W. Mintz reports an interesting case of primary tuberculosis of the parotid gland. The patient, a child three years of age, gave a maternal tuberculous history. In the left parotid region there developed a pea-sized painless tumor which gradually increased until it considerably encroached upon the neighboring tissues. The skin over the tumor was unchanged in appearance and freely movable. Inspection of the mucous membrane of the mouth and pharynx showed nothing abnormal. The tonsils were not diseased. No evidence of tuberculosis in any other region of the body was obtainable. There was no increase in the body temperature. Ordinary methods of treatment were tried without avail, and operation was resorted to. After removal, the tumor was submitted to bacteriological and pathological examination. Tissue sections stained by the Ziehl-Neelsen method showed the presence of numerous tubercle bacilli. The pathological examination showed characteristic tuberculous changes, and the presence of "giant" cells in great numbers. Very few cases of primary tuberculous infection of the parotid gland have hitherto been reported. The portal of entry of the microorganisms is obscure, but it seems fairly probable that in this instance the bacilli [illegible] to the gland through its excretory duct. —[illegible]

Hydrocyanic Acid Gas in Public Health Work.—[illegible] [illegible] and William [illegible] [illegible] [illegible] [illegible] [illegible] The gas is extremely dangerous to man, and is very [illegible]. [illegible] [illegible] of this gas [illegible] [illegible] in the [illegible] of yellow fever [illegible].—*Maryland Medical Journal.*

The Treatment of Wounds in War.—W. Watson Cheyne holds that the treatment of the injuries sustained in certain parts of the body on the field of battle is not up to the requirements of modern surgery and cannot be brought up to these requirements owing to the circumstances under which the injuries occur. If there were better arrangements at present [illegible] in the first place, proper supplies of lotions and boiled water, proper illumination, [illegible] necessity for transporting the wounded to a distance, and increase in the personnel, we could then look forward to a more efficient attempt being made to carry the advances of modern surgery into military practice. Then especially more efficient efforts could be made to disinfect and treat bad compound fractures, to see that all cases of wounds of the skull were trephined as early as possible, to open the abdomen in cases where the wound was over a fixed portion of the intestine, and when, therefore, injury of the tissue was probable, and so on.—*The Birmingham Medical Review.*

A Case of Adiposis.—Augustus A. Eshner reports the case of a woman fifty-nine years old, who complained of dyspnea, pain in the shoulders and knees, and general obesity. Two years previously there had been shooting pains in the bones, especially in the lower extremities. Shortly afterward the legs began to swell, the swelling at times disappearing to return subsequently. Swelling of the knees persisted and was attended with pain which was aggravated by movement and manipulation. The patient had been increasing in size for several years, and complained of pain in the muscles. She was found to be extremely obese, particularly about the shoulders and thighs, and the breasts and abdomen were pendulous. She was of large stature and face, weighed 251 pounds, and was unable to walk unaided. She suffered from gastric distress with nausea and vomiting. The author raises the question whether abnormal fat deposit or accumulation may not be dependent on faulty function of the thyroid gland.—*Medicine.*

The Locomotive and the Bull.—It is related of Dr. M. P. Ravenel of the Veterinary Department of the University of Pennsylvania that when, at the International Congress for Tuberculosis recently held at London, he arose in his section to read a carefully prepared paper in support of the inter-communicability of human and bovine tuberculosis, after Koch had issued his pronouncement to the contrary, the diffident American related the story of a bull that got on the railroad track in front of an oncoming express train, and chose to await developments rather than yield his ground. At the conclusion of the able and convincing paper of Dr. Ravenel, he was asked by one of the participants which was locomotive and which bull.

Patients with Chronic Interstitial Nephritis are particularly liable to bleed from various parts of the body. The [illegible] of itself rarely dangerous. Indeed, it [illegible] [illegible] all that is necessary is to keep the patient quiet. With cerebral hemorrhage, particular care is necessary. The bowels should be [illegible] with some quickly acting purgative [illegible] taken, and the patient should have nothing to [illegible]. The head of the bed should be raised. [illegible] should be avoided.—Dr. William Hale White, *London Practitioner.*

Relation Between Insanity and Renal Inadequacy.—The question of the relation between insanity and renal inadequacy is one of great importance not only from the point of view of treatment, but also from the fact that cases of insanity arising in connection with renal disease may often be treated successfully without being removed to an asylum. That the disease of the kidney is the primary lesion in certain cases is proved by many instances, but it is probable that mania and melancholia do not usually make their appearance without some other factor such as alcoholism or hereditary tendency to insanity being present.—Dr. Batten in *Practitioner.*

Keeping the Sea Fresh.—One of the most recent discoveries of Professor Hensen, the German State marine biologist, is of bacteria which keep the sea fresh by attacking the surplus organic matter in it. Other researches in Plankton show that in some places the sea is a mass of liquid food, which fish and birds inhale, and [illegible]. Even round the Arctic and Antarctic poles, this minute life exists in such a quantity as to permeate and color the sea.—*The Nineteenth Century and After.*

The Tea-Kettle for Soldiers.—The London *Hospital* says: "Recent advocacy of what we have termed the policy of the tea-kettle has raised again the old bogie of the unhealthfulness of boiled water. Curiously enough, certain officers of the R. A. M. C. are stated to be adherents of this faith. Now we know why tea causes dyspepsia. It is all the boiling of the water."

Books Received.

While the MEDICAL RECORD *is pleased to receive all new publications that may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it unless, in the judgment of its editor, it will be of interest to its reader.*

ON THE PROGRESS OF PUBLIC HEALTH ORGANIZATIONS IN THE UNITED STATES.*

By STEPHEN SMITH, M.D., LL.D.,
FIRST PRESIDENT OF THE ASSOCIATION.

MR. PRESIDENT AND MEMBERS OF THE ASSOCIATION: I esteem it a great privilege to be permitted to attend the first meeting of the American Public Health Association in the twentieth century. Since its inception a period of about thirty years has elapsed, which, in the ancient mortuary statistics, indicates that a generation of the human family has passed across the stage of life. When your honored President, my long-time friend, intimated to me that it would be appropriate on this occasion to have some words of greeting, counsel, and encouragement from those who were active in the organization of the association, I examined the list of first members to determine who could most acceptably perform that duty. It was painful to notice the havoc which death had made in our ranks in a generation. Elisha Harris, Edwin M. Snow, John H. Rauch, Ezra M. Hunt, Charles B. White, James E. Reeves, Henry I. Bowditch, James L. Cabell, Joseph M. Toner, are historic names in the annals of sanitary reform in this country. On this review I am constrained to announce, in the language of the messengers who came to the patriarch Job in his afflictions and said, "I only am escaped alone to tell thee."

The chief or immediate object which the first promoters of the association had in view was by organized effort to unify the work of those actively engaged in the administration of public health laws and to nationalize sanitary authority in municipal, State, and national governments. At that period the foundations of our national system of sanitation of cities and villages had but recently been perfected in the establishment of the Metropolitan Board of Health of New York, created by a sanitary law largely English in its origin. For this law the country is indebted to the late Hon. Dorman B. Eaton, an early and active member of this association. It formed the basis of the subsequent health legislation of the different States, and may justly be considered the most perfect code of sanitary law that has yet been placed on the statute books. Competent health organizations then existed only in a few cities, notably in Chicago, Washington, Boston, and New Orleans. But even these health boards, with the exception of the Metropolitan of New York, were feeble compared with those now filling their places. The agitation, however, in favor of stringent health laws and their efficient enforcement was becoming more and more intense in all parts of the country, and it was apparent that there should be combined action on the part of all the workers in this new field of reform. To secure the co-operation of all the forces and influences tending to enforce sanitary legislation throughout the country this association was projected. It required scarcely more than the suggestion that such an organization was essential to the reform movement to bring into active sympathy and cordial co-operation the constituent members of the association, and at once the organization was perfected.

The growth of public health administration in this country under the fostering care of the association has even exceeded the most sanguine anticipations of its founders. Thirty years ago there were not more than three or four well-organized municipal boards of health in this country, but to-day there is scarcely a community having a civil organization that has not, as an integral part of its government, a public health department. State boards of health were almost unknown at that period, but now they exist in nearly every State, and by their good work commend themselves to the confidence and support of the people.

At the first meeting of the association the initial step was taken to create a central sanitary authority in connection with the general government, but it was nearly ten years later and only in the immediate presence of a wide-spread and fatal epidemic of yellow fever that a National Board of Health was organized. Thus, within a single decade, this association had been largely instrumental in the development of a complete system of public health administration in this country, viz., municipal, State, and national. Unfortunately the law which gave the National Board of Health its powers and financial support continued in force but four years, and at the end of that period Congress refused to re-enact it. The result was that the board practically ceased to exist at the end of that period. It is now upward of twenty years since the National Board of Health was deprived of its powers, and during that period our national system, as originally devised by the members of this association, has remained incomplete.

The advice which I think the constituent members of the association would give you at this first meeting of the century would be to remedy this defect in our national sanitary system at the earliest practicable period. Our government, whose jurisdiction now extends over peoples of every grade of civilization, living under every variety of climatic conditions, requires a central sanitary authority competent to answer wisely, and in conformity with the latest teachings of science, the multiform questions relating to the public health of this heterogeneous population which must from time to time be determined in its councils. The failure hitherto to secure from Congress such legislation as would give the country a proper public health organization at Washington is largely due to the want of harmony of opinions of those who have sought such legislation, and the opposition of the Marine Hospital Service, which very naturally desires to retain its position. The want of harmony arises from the fact that comparatively few of those who approach Congress on this subject are competent to form a correct opinion as to the nature and character of the public health service which the government requires. This association alone is qualified to pass judgment upon a bill to organize that service, and should assume the duty and aggressively persevere until it accomplishes its object.

---

*An address before the American Public Health Association at Buffalo, New York.

It is a fact not generally known that some of the first members of the association regarded the Marine Hospital Service as well adapted to become the future public health department and endeavored to promote its advancement to that position. It may interest the present members if I refer to that early history, and possibly these facts may be useful in your deliberations.

At the close of the Civil War, the Marine Hospital Service had practically ceased to have any useful duties to perform, and one Secretary of the Treasury had urged Congress to abolish it. Originally created at the close of the eighteenth century, in imitation of the English system of caring for her sailor, a man before the mast, its functions in a great measure ceased when the steamship supplanted the sailing vessel in ocean and river transportation. In the former vessel the sailor's home was on the sea and his government cared for him when sick or disabled; in the latter vessel he had his own home at the port and cared for himself.

At this critical period in the history of the Marine Hospital Service, when, technically, there were but few sailors requiring government care, and a Secretary of the Treasury had advised the abolition of the bureau, Dr. John M. Woodworth, late a surgeon of volunteers, was appointed its chief officer or Supervising Surgeon-General. Dr. Woodworth was a man of culture, of polished manners, a good organizer, and an enthusiastic student of sanitary science, as then understood. He was an early and active member of this association.

In discussing with him the future of the Marine Hospital Service, I urged the importance of "first assuming, as far as possible, all the duties connected with the quarantines of the United States, which grow out of the powers exercised by the Secretary of the Treasury over the customs. If he should succeed in demonstrating the value of medical authority in determining incidental health questions arising in the management of quarantines under local administration, the tendency of the department would be to give the Marine Hospital Service jurisdiction over all similar questions. Meantime additional legislation might enlarge its powers and duties in the management of quarantines, until it might attain, first, to a supervisory, and, finally, to an absolute administration of their affairs. Advancing along these lines, without any other rival in the field, the Marine Hospital Service would naturally assume more and more the position of a central authority on all questions relating to the public health which come under the cognizance of the general government. Thus, the bureau might in time become, if not a health department, at least the permanent branch of the government service devoted to public hygiene."

Dr. Woodworth acted on the suggestion, and, until his death in 1879, steadily pursued the policy of making the Marine Hospital Service the central authority in the control of the quarantines of the United States. His first act was an official examination as to the condition and efficiency of all the quarantines, under the direction of the Secretary of the Treasury. This investigation extended to ports where either no quarantines existed, or only some unexecuted municipal regulations governed the entrance and exit of vessels. The result of this inquiry was an act empowering the Secretary to make additional rules and regulations for quarantines which were defective and require their enforcement. In case of failure in compliance by the local authorities, the Secretary was authorized to proceed to put the new rules into operation. In addition to these extraordinary powers conferred by Congress on the Treasury Department, the law provided that the Secretary should establish and maintain, under his exclusive control and management, quarantines at ports where none existed, but where, in the opinion of the Secretary, the public health required the enforcement of quarantine regulations. The execution of this law naturally devolved upon the Marine Hospital Service, and aggressive action was immediately taken to secure its benefits. Lax and inefficient quarantines were rendered effective, and new quarantines were established at many unprotected ports. This was a decisive step in the direction of placing the quarantines of the country under the exclusive control of the Federal Government. The result of this legislation was of the first importance to the sanitary interests of the country, and gave a permanent position to the Marine Hospital Service.

In 1878 there was much alarm over the matter of the admission of rags from foreign ports, and the President, by virtue of the power given him by the previous quarantine law, authorized the Secretary of the Treasury to make rules governing the quarantines in their reception of this article. Dr. Woodworth gave me the original order, prepared and signed by President Hayes, remarking, "This is a historical document which begins a new era in the history of the Marine Hospital Service."

Later in the same year occurred the great yellow-fever epidemic, and circumstances greatly favored the Marine Hospital Service, for it became not only the center of information in regard to the daily progress of the pestilence, but also the medium of distribution of the charitable funds and supplies to the stricken Southern communities.

Another event of much importance was the appointment of a Commission to investigate the facts in regard to the outbreak of yellow fever by visiting the localities where it had prevailed. This was due to the suggestion of Mrs. Elizabeth Thompson, a wealthy philanthropic lady of New York, who proposed to me to give liberally to a fund for the employment of a competent body of experts. I immediately communicated with Surgeon-General Woodworth, and urged him to accept the offer, appoint the commission, and be responsible for its work. He replied favorably, the money was contributed by Mrs. Thompson and others, the commission was appointed by Dr. Woodworth and was composed of Southern physicians of large experience in the treatment of yellow fever. The investigation proceeded during the autumn months.

The epidemic of that year proved to be a national calamity and aroused a popular interest in methods of prevention hitherto unknown. Sanitary authorities in all parts of the country were appealed to for advice and assistance, especially with reference to the proper measures to prevent the return of the pestilence in the following year. The only body competent to answer that question was the American Public Health Association. Its officers decided to call the annual meeting in Richmond, Virginia, and devote the session especially to the late epidemic. Surgeon-General Woodworth consented to present the results of the commission's work as a basis of discussion.

It became evident long before the meeting of the association that whatever might be the special views in regard to preventive measures, the question which would dominate the association would be: "What form of health organization shall be created in the general government to meet the exigency of a recurrence of the epidemic in the following year?" All great advances in health legislation result from the devastations of epidemic pestilences. It is only under the stress and strain of an epidemic that has destroyed thousands of lives, wasted millions of dollars, and created universal terror, that adequate public health laws can be enacted and effective administrative organizations can be established. The yellow-fever epidemic of 1878-79 had this effect, and it became the earnest effort of the members of this association to improve the opportunity to the best advantage.

The excellent work performed by the Marine Hospital Service naturally placed it in a most favorable position before the public, and its friends endeavored to formulate a bill which would commend itself to Congress and would make that service the future national sanitary authority. In conference with Dr. Woodworth, we determined that a bill creating a Department of Public Health, on the same basis as the Department of Agriculture, would be in accordance with previous legislation, and thereby meet with less opposition. Such a bill was to provide for a bureau devoted to the duties of the Marine Hospital Service and other bureaus having the quarantine and public health services in charge. I drafted such a bill, and it was introduced in the Senate at the opening of the session by Senator Lamar of Mississippi. Like many other bills before Congress, designed to create a public health service, it met with opposition from other departments at Washington, jealous of the growing power and popularity of the Marine Hospital Service. Though this opposition had been apparent for years at the annual meetings of the association, it did not take active form until the meeting occurred at Richmond. There it became so obstructive that no practical results were reached by the association. At the ensuing session of Congress the same opposition was an organized force that resisted every form of legislation which might, in any manner, favor the advancement of the Marine Hospital Service. The result was the passage of a bill on the last day of the session, creating a mere skeleton of a board of health, with no power whatever, for either good or evil. When the people of the affected districts of the South learned that Congress adjourned without providing any safeguards against the return of the epidemic, the greatest indignation was manifested. In some districts it was reported the members of Congress were threatened with violence, if they returned without affording adequate relief to their threatened danger. Fortunately, an extra session of Congress was called, and the Southern members were only too happy to have the opportunity to pass a supplementary bill clothing the Board with suitable powers. This act, however, was limited in its operations to four years. During this period the board faithfully performed all the duties imposed by law and sought to organize a system of national quarantine administration and interstate sanitary supervision of commerce and travel in harmony with the most advanced views of authorities. But with the lapse of the supplementary law, and in the absence of any impending epidemic, the Secretary of the Treasury conferred upon the Marine Hospital Service the power to expend the funds formerly appropriated to the National Board, thus bringing that bureau prominently forward to the position it formerly occupied, but with the added powers exercised by the latter body. From time to time Congress has increased its quarantine and public health duties, and added to its equipment. It now has its own building, like a department of government, with laboratories where the most accurate studies are made into the causes of contagious and infectious diseases, into the value of different disinfectants and vaccines, and where antitoxic sera are manufactured and distributed. It has a large and highly qualified staff of medical officers, appointed by the President, after competitive examination; it maintains in foreign ports where epidemic diseases prevail medical officers who give constant information to home quarantines and issue bills of health to vessels bound to the United States; it has under its own supervision a large number of insular and interstate quarantines; and, finally, it is ready at any moment to aid State and municipal sanitary organizations in their efforts to suppress epidemic diseases.

It appears from this review that for a period of upward of thirty years the Marine Hospital Service has steadily advanced in the direction of becoming the Department of Public Health in the General Government until it requires little more than an adjustment of its organization to the new career upon which it would enter to fulfil every requirement of that position. As the original promoters of this association gave the first impulse to the Marine Hospital Service along the lines of development which would place it at the head of our national sanitary system, and as it has advanced along those lines until it is prepared to assume the rank and title and perform the duties of our central sanitary authority, I may be permitted to suggest that this association should recognize these historical facts and the present situation of our public health service and, unless there are conditions not apparent to the public, begin the new century by inaugurating the Marine Hospital Service as such authority. The efforts that have been made in the past to secure from Congress legislation creating some other form of health organization, have proved futile, and the future promises much less success, owing to the constant advance of the Marine Hospital Service in public and Congressional favor. If I understand the objections to that service on the part of those seeking a better form of organization, it is chiefly that the public health authorities of the country have no part in its councils. It would not be difficult, in my opinion, to remedy these and other defects, if this association exercised its friendly offices with the chief officer of that service in securing necessary legislation. These suggestions are submitted with much diffidence to the better judgment of the association.

Mr. President: It would ill become me to attempt to detail to the members of this association the contributions of sanitary knowledge and experience by the last half of the nineteenth to the first half of the twentieth century. It is sufficient to state that through the labors of its Pasteur, the mysterious realm of the causation of epidemic diseases has been thoroughly explored and the nature of their causes has been made known; through the labors of its Koch, the life history of these causes has been accurately determined; through the experiments of its Lister, the agencies which destroy these causes and arrest their destructive processes have been placed in the hands of every human being. The century closed with the warfare of man against the multiform and manifold causes of disease which beset him on every hand in the flood-tide of success. If that warfare is pressed as vigorously during the twentieth century as it has been in the last decade of the nineteenth century, it will require no great stretch of the imagination to anticipate that long before this century closes, the whole brood of pestilential or communicable diseases will be exterminated from the earth, and man will reach his normal period of life—*one hundred years.*

Mortality Among Soldiers.—Under favorable conditions of peace, says an English weekly, the mortality among soldiers is practically the least known, with a death rate of only 5 in every 1,000. Compared with a soldier's life, the placid days even of a clergyman are full of danger, for his death rate is 11 in 1,000, or more than twice as great as that of his militant brother.

OFFICIAL AND PRIVATE PHTHISIOPHOBIA.

THE MEDICAL, SOCIAL, INTERNATIONAL, AND HUMANITARIAN ASPECTS OF THE GOVERNMENT DECREE TO EXCLUDE NON-PAUPER TUBERCULOUS IMMIGRANTS OR CONSUMPTIVE VISITORS TO THIS COUNTRY.

A PLEA FOR A SUPERIOR BOARD OF HEALTH OR COMMISSION ON TUBERCULOSIS AND A NATIONAL TUBERCULOSIS ASSOCIATION.*

BY S. A. KNOPF, M.D.,
NEW YORK.

To my deep regret I learned recently from an authentic source that new difficulties have arisen concerning the site of our future New York State Sanatorium. Phthisiophobia, or exaggerated fear of the vicinity of consumptives, is the cause. The neighbors object and will make heroic efforts to prevent the sanatorium from being located in that place. Our symposium on sanatoria to-night will do us little good if we do not also consider means to treat this new and rapidly spreading disease. Worst of all, we have now not only individuals and some local governments, but even our Treasury Department, representing the head of the United States Marine Hospital Service, afflicted with phthisiophobia.

Some weeks ago I was invited to give expert testimony before Judge Thomas of the United States Circuit Court in Brooklyn in the case of Thomas P. Boden, the Irish immigrant who was detained by the immigration authorities because he was suffering from consumption. My testimony to the effect that pulmonary tuberculosis was not a dangerously contagious, but only a communicable, malady, that the contact *per se* could not transmit the disease, and that ordinary precautions with the patient's sputum and other secretions would suffice to do away with all danger of infection was overruled by the judge upon motion of the counsel for the Government. Exception was taken by Mr. Francis Tracy Tobin of Philadelphia, the counsel for Mr. Boden, and if the former should succeed in bringing this case before the Supreme Court of the United States, this, the highest tribunal of our country, will have to decide a most momentous question. The issue involved not only affects the few consumptive immigrants who may arrive at our ports, but it also affects the several thousand American citizens suffering from pulmonary tuberculosis.

On the strength of a declaration of the Surgeon-General of the Marine Hospital Service that pulmonary tuberculosis is a dangerous contagious disease, the Superintendent of Immigration issued last June an order that in future immigrants with tuberculosis of the lungs must be debarred from all ports of the United States regardless of boards of special inquiry, which heretofore had used their discretion in the matter. Formerly the Board of Special Inquiry at this port, after receiving the report of a case of tuberculosis from the Chief of the Medical Division of the Immigration Service of New York, could exercise discretion as to the admission of the person, and there have been instances in which a child ill of the disease has been permitted to land with its parents; but henceforth no one with consumption will be admitted to the country. This rule applies to alien passengers in the first and second cabins, as well as to those in the steerage.

Is this declaration, issued by the Surgeon-General of the Marine Hospital Service, and strengthened by the authority of the Treasury Department, based on scientific observation? Is this opinion shared by the great authorities on the question of tuberculosis and the medical profession of the United States in general?

Ever since the discovery of the tubercle bacillus it has been demonstrated by clinical and bacteriological experiments all over the civilized world that the germ alone is the direct cause of the disease, and without its presence tuberculosis cannot be conveyed. The bacilli are usually contained in the expectoration, more rarely in other secretions, very rarely in the muscular or osseous or cutaneous tissue. Thus, as stated above, the contact *per se* of a consumptive individual does not transmit the disease, and pulmonary tuberculosis is not a contagious, but only a communicable, malady. The destruction of tuberculous expectoration and other secretions and of tuberculous food substances, suffices to do away with all danger of infection and transmission. Therefore there is no scientific basis on which to classify pulmonary tuberculosis among the dangerously contagious diseases, and it is contrary to the results of the experience and the experiments of all who have studied the question thoroughly.

Now what have the great European and American medical authorities to say on this subject? Koch, the discoverer of the tubercle bacillus, says in this connection in his recent London address, which I quote verbally, since it was delivered in English: "A consumptive who coughs out tubercle bacilli is not necessarily a source of infection on that account so long as he takes care that his sputum is properly removed and rendered innocuous." Professor Hermann M. Biggs, whose splendid work in the prevention of tuberculosis was most highly commented on by Koch in the same address, declares in the circular issued by him through the New York Health Department: "If the matter coughed up be properly destroyed, a person suffering from consumption may frequently not only do his usual work without giving the disease to others, but may also thus improve his own condition and his chances of getting well." This circular has served as a model to many health boards in this country and abroad. Concerning the action of the Treasury Department in regard to tuberculous immigrants—not paupers—Dr. Biggs pronounced it unscientific, unwise, unnecessary, and inhumane. Dr. T. Mitchell Prudden, professor of pathology and bacteriology at the College of Physicians and Surgeons, declares distinctly that pulmonary tuberculosis is a communicable and not a contagious disease.

For the United States Government to declare pulmonary tuberculosis to be a dangerously contagious disease, in spite of the opinions of these great authorities, stamps several millions of American citizens suffering from consumption with a stigma wholly undeserved. That the general profession is in thorough accord with the opinions expressed by Professors Prudden and Biggs may be gleaned from editorials which appeared in four of the leading American medical journals. Dr. Frank P. Foster of the *New York Medical Journal* says in an editorial of June 22d: "It is our conviction that the United States Bureau of Immigration, if it has really determined upon the course of indiscriminately excluding consumptive immigrants from the country, as has been announced, has been ill-advised. . . . . What the people need to be taught—and they have already partly learned the lesson—is not that pulmonary tuberculosis is a monster to be fled from, but that it is a danger that can be effectively overcome. Even if this were not true, it remains a fact that the policy of selfishness and inhumanity, pursued to the end, rarely, if ever, proves to be for the general welfare of those who follow it." Dr. George M. Gould, in *American Medicine* of November 30, says in the leading editorial entitled "The Deportation of Consumptive Immigrants": "We think professional and lay opinion will not justify the exclusion of tuberculous immigrants on the simple ground that the disease is 'contagious' or 'communicable.' It is only so in such a low degree that the severe measure of exclusion for this reason alone seems unjustifiable." Dr. George H. Simmons, editor of *The Journal American Medical Association*, in criticising the indiscriminate exclusion, says: "Even hopeless consumptives may sometimes bring some good," and cites Robert Louis Stevenson as an example.

---

*Read before the New York Academy of Medicine at its meeting of January 2, 1902.

The Government decision to classify pulmonary tuberculosis as a dangerously contagious disease has only been in operation for a few months, but it has already had its consequences by increasing the fear of people to associate with consumptives. Healthy employees have been discharged because some one of their near relatives with whom they were living were reported to their employers to be suffering from consumption. I have learned of numerous similar cases and very recently two came under my personal observation. A sewing woman who had been employed frequently by a wealthy family mentioned incidentally that her sister was being treated for tuberculosis of the lungs, but was getting along very nicely. The result was that the poor woman was discharged and never employed again by the same family. A similar thing happened within this week to a poor washerwoman. Professor A. Jacobi, of this city, spoke to me of a number of cases in which persons lost their positions for no other reason than that they suffered from a cough. One case he mentioned seemed to me particularly pathetic. A man with a large family to support, but strong, vigorous, and of excellent physique, was discharged from employment because of a cough which did not get well fast enough to suit his employer. How much suffering and hardship may thus be daily created, only those who come in contact with poor consumptives can appreciate.

According to the MEDICAL RECORD of December 28, the Health Board of Liberty, N. Y., has ordered that no hospital or sanatorium for the reception of consumptives shall be maintained within the village limits, and that tuberculosis shall be classed as an infectious disease, like smallpox and diphtheria, and sufferers from it be reported and quarantined if thought necessary. The editor of the MEDICAL RECORD, Dr. George F. Shrady, very justly adds: "This is one of the logical results of the intemperate outcry regarding the infectiousness of tuberculosis, another being the ridiculous and cruel attempt of the immigration authorities to prevent the entrance into this country of any tuberculous subject."

Whether or not the Liberty Board of Health is justified to inaugurate such extreme measures, I am not prepared to say. If this agitation is directed against the numerous boarding houses which receive tuberculous patients who are under no medical supervision whatsoever, there may be justification for rigorous measures. To direct such a movement against well-conducted sanatoria seems to me folly, for there is nothing to fear in regard to infection from such institutions; and, according to my experience, one is safer in such places from tuberculous infection than anywhere else. Whatever the future attitude of the Liberty Board of Health may be, I would like to recall to them the story which I related in my article, "Are Sanatoria for Consumptives a Danger to the Neighborhood?" which appeared some five years ago in the MEDICAL RECORD, October 3, 1896: "Near Vienna there existed a place which had been known for years as a health resort for consumptives and persons suffering from similar troubles. Thanks to the efforts of a distinguished professor and specialist in phthisio-therapeutics and the funds given by a wealthy philanthropist, it had been decided to found a sanatorium for poor consumptives, under the direction of this professor, in the resort mentioned. But the authorities of the community raised such an outcry at the prospect of having this institution in their midst, fearing it would drive away the class of wealthy patients who had come there for so long, that the professor, not wishing to go where his sanatorium would not be welcome, chose another locality. They thought they had done a wise thing; but soon the wealthy patients, thinking that the new place must possess superior advantages to have been chosen by so celebrated a specialist for his institution, began to flock thither. The old resort, so favored for years, found itself quite deserted.

To our friends in Liberty, as well as in the Adirondacks, who fear contagion from sanatoria, I will simply say that if they desire I am able to furnish them with official statistics for over fifty years, whereby it is conclusively proven that, since the establishment of sanatoria for consumptives, the mortality from tuberculosis among the villagers of Goerbersdorf and Falkenstein—the two places where five of the most flourishing German sanatoria are now existing—has actually been decreased by one-third of that which it was before the establishment of the institutions. The explanation for this remarkable decrease of consumption in the villages of Goerbersdorf and Falkenstein is simply to be sought in the fact that the villagers imitated voluntarily the clean habits which were obligatory for the sanatorium inmates. The fallacy of exaggerated fear of tuberculous patients has been shown again and again. Some two years ago when a few overzealous California statesmen tried to exclude consumptives from the Golden State, their attempt was ridiculed by the medical profession and laymen of their own State.

All physicians approve of earnest and intelligent measures to prevent the spread of tuberculosis; but to exaggerate the danger by declaring consumption, which is a chronic, preventable, curable, and only communicable affliction, to be a dangerously contagious malady, we only create another disease in the minds of the people which may justly be called phthisiophobia. We should not encourage this new malady, privately nor officially. Neither official nor private phthisiophobia will help us in the antituberculosis crusade. Education of the masses through societies for the prevention of tuberculosis, instruction in schools and colleges, and a co-operation of the family practitioner with the health authorities, without inflicting burdens and hardships on either physician or the patient or his family, will be to my mind a more judicious procedure and prove more effectuous than any draconian measure.

By excluding pauper immigrants, whether tuberculous or not, the immigration authorities do their duty, and every loyal American citizen must approve of it; but by excluding consumptive aliens of means, or at least such as can give evidence that they will not become a burden to the community, we may subject ourselves to retaliatory measures on the part of other governments, and wealthy American pulmonary invalids may no longer be allowed to enjoy the hospitality at foreign health resorts. Thus the case has an international as well as a national aspect.

Concerning the humanitarian view of the case, I have to add but little to the exposition of Professor Biggs and Drs. Foster, Simmons, and Doty. Since the ruling of the Secretary of the Treasury that pulmonary tuberculosis is a dangerous contagious disease within the meaning of the statute, all certified cases of tuberculosis are returned without discrimination. Parents may thus be separated from their children, husband from wife, brother from brother, sister from sister, friend from friend, because of a law founded on an unscientific basis, contrary to all social interests of our own country, derogatory to our interests in our relation to other countries, contrary to the American spirit of justice and humanity.

Have those who by this decision stamped every American consumptive as one afflicted with a dangerous contagious disease ever thought how really few families there are who have not at least one, more or less near, relative or friend who is a consumptive? Tuberculosis is the most frequent of all diseases and it is most prevalent in the pulmonary form. It is a disease of the young and the old, the poor and the rich, the East and the West, the North and the South.

May the wise judges of the Supreme Court, who it is to be hoped will soon be called on to consider the matter, view it in all its aspects and decide it in the light of our present knowledge which makes the consumptive not a hopelessly ill individual, afflicted with a dangerously contagious disease, whose contact we have to fear, but which declares him only suffering from a communicable and at the same time easily preventable, and in many instances very curable, disease.

Unfortunately, we have not yet in this country the often pleaded for "Superior Board of Health," with its seat in Washington, the equivalent of the "Reichs Gesundheitsamt" of Germany, or the "Conseil Superieur de Sante Publique" of France, where such important questions appertaining to the health and welfare of the nation can be decided for all the States of the Union. Emperors and kings and the governments of European countries have for the past years been making tuberculosis an issue to be dealt with, not by extreme sanitary measures, but by the creation of national, provincial, and private sanatoria for the treatment of the consumptive poor and those of moderate means. In some States and in some cities of the United States there is now a praiseworthy activity to create similar institutions, and also to remove some of the causes of the spread of tuberculosis, such as bad tenement houses, overcrowded institutions, etc. A very important statement in relation to this subject was made a few months ago by Edward T. Devine, Ph.D., the distinguished charity worker and editor of the weekly review called *Charities*. Refuting the assertion that the prevalence of tuberculosis in some parts of New York City is directly due to the tide of aliens flowing to our shores, he maintains the contrary by emphasizing the relative rarity of this disease among immigrants. Dr. Devine says: "The freedom of immigrants from pulmonary tuberculosis is due to the fact that almost without exception they come from rural districts, but when subjected to the privation of light and air in the worst of New York's tenement-houses, they become ready victims of the disease. This is only another instance of the truth that the evils existing in our slums are in great part due to our own neglect rather than to the influence of the foreigner who is obliged to live there." (*Charities*, October 26, 1901.)

I trust that our enlightened President, Theodore Roosevelt, will soon follow the example of his colleague, the President of the French republic, and the other rulers of European countries, such as King Edward of Great Britain, the Emperor of Germany, the Czar of Russia, the King of Norway and Sweden, the Queen of Holland, etc., by creating a governmental tuberculosis commission. This commission should have for its aim the study of the best and most humane means to combat tuberculosis as a disease of the masses, and to suggest to the United States Government the best prophylactic and curative measures to arrest the disease which costs so many valuable lives every year.

In Europe, particularly in England, Germany, and Austria, the example of noble-minded princes and rulers, in erecting and maintaining private sanatoria for the consumptive poor, has been emulated by the aristocracy of birth and finance of those countries. There are now, as a result of this agitation, hundreds of inland sanatoria throughout Europe devoted exclusively to the treatment of consumptive adults, and numerous seaside sanatoria for tuberculous children. Our Canadian neighbors are also ahead of us in the antituberculosis crusade. There exists in Canada a National Sanatorium Association, the objects of which are, first, to establish institutions for the isolation, treatment, and cure of persons affected with pulmonary tuberculosis; second, to check the spread of this dread disease in Canada through educational and legislative measures.

This association, which was incorporated by special act of the Dominion Parliament of 1896, has for its President Lord Strathcona and Mount Royal, for Vice-President Sir William Ralph Meredith, and for one of the Trustees the Premier of Ontario, the Hon. G. W. Ross, LL.D.

A similar movement under the auspices of our governmental heads would doubtlessly result in the creation of multiple sanatoria in the United States. There is enough wealth and good will among our philanthropists to assure the very best results, if, for example, a national sanatorium association, of which the President of the United States would be the honorary president, would be formed.

I believe I can speak for the majority of the American profession by saying that they would welcome such a movement most cordially, and give it their hearty co-operation. The profession and health boards should unite in the educational work. There should be a mutual understanding between these two factors for the common good. When the education of the masses concerning tuberculosis will be directed by a United States superior board, or commission, of health, consisting of trained sanitarians and medical practitioners, the policy pursued will discriminate justly between frightening and educating people into obedience of sanitary regulations.

With the creation of such a health department, or commission, in Washington, with a successful sanatorium movement throughout the country, the co-operation of physicians, local health boards, philanthropists, and an intelligent people, there is no reason why the United States should not be the first country in the world to conquer this great foe of mankind, so justly called by our immortal Oliver Wendell Holmes, "the great white plague."

16 West Ninety-fifth Street

Alien Insane.—There are 24,000 inmates in New York hospitals for the insane, 50 per cent. of whom are foreign-born, although only 25 per cent. of the State's population is alien. In 1890 the native-born population of this country constituted 84 per cent. of the total, while the native-born insane constituted only 65 per cent. of the total.

A CONTRIBUTION TO THE PATHOGENESIS OF NARCOLEPSY AND OTHER FORMS OF MORBID SLEEPINESS.*

By HEINRICH STERN, Ph.D., M.D.,
NEW YORK.

Pathological somnolence in general, and narcolepsy in particular, have not found that universal consideration and discussion which their import and their by no means infrequent occurrence demand.

Almost every communication upon these subjects comes from the pen of a neurologist, and it seems plausible that to this fact may be ascribed the supposition of the profession in general that the study and treatment of these morbid states belonged to the domain of the nerve specialist exclusively.

However, the primary factor in the causation of pathological sleep, like the prime inducer of normal sleep, with few hypothetical exceptions, does not arise in the brain, and therefore does not concern the neurologist alone. Moreover, the pertaining neurological literature at my disposal is almost entirely limited to the relation of cases, their classification, and the discussion of their clinical features. No decided attempt seems to have been made to arrive at a proper understanding of the underlying causes.

To designate a given instance of narcolepsy or other form of abnormal somnolence as epileptic, epileptoid, or hysterical in character, or as of toxæmic origin, may be invaluable for clinical purposes, but to the pathologist it signifies little or nothing.

The term narcolepsy implies a sudden, uncontrollable inclination to sleep, occurring repeatedly and after varying intervals. Gélineau,[1] in 1880, was the first to describe the narcoleptic attack. Valuable contributions to the subject were furnished by Dana (Putzel),[2] Cremen,[3] Berkhan,[4] Dehio,[5] Jacoby,[6] McCarthy[7], Nammack,[8] and some others. The latest writers upon the subject, Furet[9] and Sainton,[10] look upon narcolepsy as a manifestation of autointoxication. Furet again draws attention to the fact that seizures of pathological somnolence may occur in the course of nutritive disorders, as diabetes mellitus and polysarcia; during the acute infectious diseases, as influenza, enteric and typhus fevers; as a consequence of alcoholism or other intoxications, and as the result of drug narcotization. He further believes that epileptic attacks, which he considers another manifestation of intoxication, are frequently synchronous with narcolepsy.

The last assumption of Furet—that epilepsy and narcolepsy are often associated symptoms of one intoxication—is certainly worth our attention, as the close relation of most instances of pathological sleep to the epileptic phenomenon would thus be easier of apprehension.

To the subject of autointoxication with reference to the production of morbid somnolence I have devoted some attention in a casual way. However, since studying the following classical case, I have been induced to give the matter more thorough consideration:

William S., aged thirty-five, unmarried, native of Ireland, four years in United States, car conductor, was referred to me for a supposed gastric disorder on April 30, 1901.

The family history does not evince any neuropathic traits. Patient is free from lues, is sexually disinclined, is a total abstainer from intoxicants and tobacco, and, with the exception of frequent attacks of gastric indigestion, that he now attributes to his former diet in which farinaceous material greatly preponderated, enjoyed good health until about six years ago. Since that time he is afflicted with daily recurrences of hyperæsthetic sensations on the forehead and eyebrows, and with sleeping seizures. The daily attacks of somnolence for the last two years have become more intense and of longer duration. In April and May of this year, his sleepiness became so great that he was compelled to discontinue his work. Since then, under an exclusive milk regimen, and with the assistance of various therapeutic measures, he is enabled to attend to his occupation, although the intensity-degree of the diurnally recurring somnolence has been hardly diminished.

The sleeping seizures occur independently of the ingestion of food, as I have convinced myself by actual experiment, and inevitably set in between ten and eleven o'clock in the morning. The spells last till three or four in the afternoon; often the trance-like condition continues for the rest of the day. The patient will fall and sleep if disengaged, and only by the utmost sheer brutal will-power is he able to resist an attack of sleepiness occurring during his working hours. That is, he tries to withstand the irresistible desire to lie down and to sleep, by holding on to the railing or the straps of the car and making pitiful efforts to keep his eyelids apart, but notwithstanding his resistance he feels that he is virtually asleep; he knows that he is but semiconscious, and that he performs his duties in an automatic way.

The patient's extreme morbid somnolence is best characterized by his own words: "Were I to fall into a pool during one of these attacks," he says, "I would be too tired to raise myself up, although I would be conscious enough to know that I may be drowned."

The patient possesses an active mind and is quick of conception. He is not a hysterical person in the sense that he is afflicted with minor phenomena of that affection. He is free from vertigo at all times. He never suffers from cephalalgia, but his head feels frequently full and heavy. He perspires profusely, especially on the hands, feet, and forehead at all times and irrespective of the prevailing temperature, but particularly before the lethargic or narcoleptic condition sets in.

While the pathologic somnolence apparently does not influence the physical condition of the patient, his physiological sleep during the night does not seem to refresh him. For when he rises after eight or nine hours of sleep, at 6 A.M., he really feels more fatigued than he did on retiring the previous night. This languor is gradually subsiding toward eight o'clock, one and a half hours after breakfast.

The physical examination of thorax and abdomen revealed nothing unusual besides the fact of a weak, slightly hypertrophied heart and a tender, dilated stomach, extending to two centimeters from the umbilicus.

An analysis of the stomach contents, after a test breakfast consisting of 500 cc. of weak tea and one dry roll, showed the following:

Gastric contents withdrawn one hour after ingestion of test breakfast: Amount withdrawn, 240 cc.; reaction, acid; hydrochloric acid, 0.36 per cent.; lactic, acetic, and butyric acids, absent; pepsin, present; activity normal (fibrin dissolution); starch, unconverted in the unfiltered contents; erythrodextrin in filtered portion.

The microscopic examination revealed: Starch granules in various modifications, fat globules, epithelium, mucous corpuscles, yeast fungi, sarcinæ ventriculi, and various non-pathogenic bacteria and increased. The stomach affection was accordingly diagnosed and treated as hyperchlorhydria. [illegible] tion, and faulty [illegible].

---

* Read at the semi-annual meeting of the Medical Society of the State of New York, October 15, 1901.

Ophthalmological Examination.—Patient has a vision of six-six in each eye. Retinoscopy revealed a partial degree of hyperopic astigmatism, axis vertical. Phorometer showed one degree of esophoria. Prisms gave the strength of convergence upward and downward about three degrees. The right eye has an outward strength of six degrees and an inward of the same amount. The left eye has an outward and inward strength equal to eight degrees. The fundus is apparently normal except that the veins are larger than usual.

Urine examination May 2 revealed the following: Quantity passed in twenty-four hours, 1,620 c.c.; color, Vogel's scale No. 3; transparency, perfect; odor and consistency normal; reaction, 0.56° acidity; specific gravity, 1,029 at 15.5° C.; total solids, 109.46 grams; salts of HCl, greatly in excess; of H_2SO_4, in excess; of H_3PO_4, increased; of CO_2, normal; free NH_3, traces; carbamid, 3.4 per cent = 55.08 grams; uric acid 1.77 grams; ratio of uric acid to carbamid = 1:31.1; xanthin, hypoxanthin present; creatinine, in excess; hippuric acid present; urobilinurin-indican slightly increased; albumin, absent; biliary acids, glucose, glycouric-acid compounds absent; microscopically distinguished, considerable amounts of crystals of uric acid, urates and calcium oxalate, mucous corpuscles, some polynuclear leucocytes, epithelium of prostate in moderate amount, of bladder and urethra in large quantities.

Blood Examination, May 2, 1901 (Microscopical). (*a*) Fresh blood.—Blood count, erythrocytes, 3,600,000 in 1 c.mm. blood; leucocytes 7,000 in 1 c.mm. blood; proportion of leucocytes to erythrocytes in 1 c.mm. of blood, 1:514.

(*b*) Dried specimens of blood.—Erythrocytes, small lymphocytes, mono- and polynuclear leucocytes, eosinophiles, neutrophiles.

Blood Examination, May 9, 1901.—Alkalescence 266.5 mgr.; NaHO in 100 c.c. blood; specific gravity, 1,057; hæmoglobin, 78 per cent; blood count, erythrocytes, 5,100,000 in 1 c.mm. blood; leucocytes, 8,000 in 1 c.mm. blood; proportion of leucocytes to erythrocytes, 1:637.

Microscopically distinguished.—Normal erythrocytes, blood plates, small and large lymphocytes, polynuclear leucocytes, eosinophiles.

A great number of urinary and blood examinations were performed between May 9 and October 7, 1901. The urine on no occasion exhibited any abnormal constituents; its daily amount averaged 1,550 c.c., its specific gravity 1,029.5; its degree of acidity, 0.53, and its contents of carbamid never exceeded 3.5 per cent.

The only urinary elements permanently in great excess, those to which to a greater part the high density seemed to be due, were the chlorides. In the twenty-four hours' urine of May 28–29, for instance, 12.09 grams of Cl were excreted. The patient's weight being at that time 65.5 kilograms, 0.1818 gr. Cl were excreted for each kilogram of body weight. This is certainly in excess of the average which amounts to 0.126 gr. Cl per kilogram of body weight.

As the patient was during that period on a milk regime to the exclusion of all other food stuffs, the amount of chlorine which he ingested with the nutriment is readily calculated. The quantity of milk daily partaken of was 7,000 c.c. In 1,000 c.c. of milk, 1.7 grams of chlorine are contained on the average. The patient ingested, therefore, 11.90 grams of chlorine every day, which corresponds about to its output by the urine in that time.

Determination of the Relative Urinary Toxicity.—June 22, 1901. Narcoleptic condition between 11 A.M. and 4 P.M. (1) Night urine, 360 c.c.; acidity, 0.62°; density, 1,033. (2) Urine voided between 6 A.M. and 10.30 A.M., 310 c.c. (prior to attack); acidity, 0.48°; density, 1,028. (3) Urine voided between 4 P.M. and 7 P.M., 120 c.c. (after attack); acidity, 0.3°; density, 1,031.

June 23, 1901. (1) Night urine, neutralized by $HNaCO_3$, filtered, possessing a temperature of 30° C., was injected into a vein of the ear of a rabbit weighing 2,050 grams.

Prior to injection, rectal temperature, 38.4° C.

After injection of 30 cc., pupil unchanged, defecation.

After injection of 48 cc., myosis, respiration very rapid.

After injection of 50 cc., rectal temperature, 38.8° C., slight rigidity.

After injection of 65 cc., respiration, 100; pulse, 140; defecation.

After injection of 75 cc., emission of urine.

After injection of 83 cc., convulsions, opisthotonus, death.

Time, eight minutes. Consequently, $\frac{83 \times 1000}{2,050} = 40.48$ c.cm. of night urine were necessary to kill one kilogram of animal.

(2) Urine voided prior to attack, treated as the night urine, of a temperature of 30.5° C., injected into an aural vein of a rabbit weighing 1,960 grams.

Prior to injection, rectal temperature, 39.2° C.

After injection of 18 cc., myosis perceptible.

After injection of 30 cc., rectal temperature, 39.3° C.

After injection of 35 cc., myosis complete.

After injection of 43 cc., defecation, pronounced tremor.

After injection of 50 cc., emission of urine.

After injection of 55 cc., respiration, 46; pulse, 152.

After injection of 65 cc., strong convulsions.

After injection of 68 cc., death.

Time, six minutes. Consequently $\frac{68 \times 1,000}{1,960} = 34.69$ c.cm. of ante-narcoleptic urine were necessary to kill one kilogram of animal.

(3) Urine voided after the attack of somnolence, treated as the night urine, of a temperature of 30.4° C., was injected into an aural vein of a rabbit weighing 1,885 grams.

Prior to injection, rectal temperature, 40° C.

After injection of 40 cc., beginning of myosis.

After injection of 45 cc., rectal temperature, 40° C.

After injection of 50 cc., myosis more pronounced; respiration, 38.

After injection of 52 cc., rigor.

After injection of 57 cc., respiratory intermission.

After injection of 60 cc., death without convulsions.

Time, six minutes. Consequently, $\frac{60 \times 1,000}{1,885} = 31.83$ c.cm. of post-narcoleptic urine were necessary to kill one kilo of animal.

October 6, 1901. Narcoleptic condition between 10.50 A.M. and 5.30 P.M. (1) Urine voided at 10.30 A.M., 125 cc.; acidity, 0.54°; density, 1,025.5. (2) Urine voided at 6 P.M., 150 cc.; acidity, 0.45°; density 1,033.

(1) Urine of 10.30 A.M., prior to attack, neutralized by $HNaCO_3$, filtered, possessing a temperature of 20.5° C., was injected into a vein of the ear of a rabbit weighing 1,620 grams.

Prior to injection, rectal temperature, 37.4° C.

After injection of 20 cc., respiration accelerated.

After injection of 30 cc., slight myosis.

After injection of 35 cc., tremor, great restlessness.

After injection of 38 cc., emission of urine.

After injection of 40 cc., respiration diminished, temperature, 37.5° C.

After injection of 50 cc., paralytic manifestations.

After injection of 55 cc., complete myosis, defecation.

After injection of 65 cc., respiration shallow, very frequent; pulse, 152.

After injection of 75 cc., convulsive phenomena.

After injection of 85 cc., convulsions, opisthotonos, death.

Time, twenty minutes. Consequently, $\frac{85\times 1,000}{1,620}=$ 52.47 c.cm. of ante-narcoleptic urine were necessary to kill one kilogram of animal.

(2) Urine of 6 P.M., first excretion after attack had abated, treated as the morning urine, of a temperature of 20.5° C., was injected into a vein of the ear of a rabbit weighing 1,675 grams.

Prior to injection, rectal temperature, 38° C.

After injection of 25 cc., slight myosis.

After injection of 30 cc., great restlessness.

After injection of 40 cc., complete myosis, defecation.

After injection of 45 cc., clonismus in extremities.

After injection of 70 cc., respiration 60, temperature 39° C.

After injection of 75 cc., heart pulsation 144.

After injection of 88 cc., convulsions, death.

Time, 11 minutes.

Consequently, $\frac{88\text{x}1,000}{1,675}=$ 52.53 c.cm. of post-narcoleptic urine were necessary to kill one kilogram of animal.

Summing up the foregoing data, we find:

(*a*) Diurnally recurring morbid somnolence.

(*b*) Free perspiration on hands, feet, and forehead at all times, and particularly so before attacks.

(*c*) Physical condition remains uninfluenced by the attack.

(*d*) Physiologic sleep does not refresh the patient.

(*e*) Weak, slightly hypertrophied heart.

(*f*) Dilated stomach and hyperchlorhydria.

(*g*) High urinary density and acidity.

(*h*) Urinary chlorides greatly in excess.

(*i*) Salts of sulphuric and uric acids, carbamid, creatinin, and calcium oxalate in excess in the twenty-four hours' urine.

(*k*) Diminished blood alkalescence; hæmoglobin somewhat reduced in amount.

(*l*) Low degree of relative urinary toxicity before as well as after the attack of somnolence.

Inasmuch as the attacks of morbid somnolence never occurred until the twenty-ninth year of the patient's life, and as he at no time met with an injury of moment, we have to conclude that a toxicosis of some kind stands at their foundation.

Ectogenesis of a specific toxic material may at once be excluded, as the patient is a total abstainer from alcohol and tobacco, as the seizures occur independently of the administration of drugs, and as the attacks continued unmodified during the last five months in which period he ingested nothing but milk.

There is apparently nothing left but to assume the autochthonous production of a toxic substance causing narcolepsia. To what degree, however, is this assumption justified?

The patient is not, nor was he since childhood, afflicted with an infectious disease; his liver performs its functions in a normal way, cholæmia is not present; renal insufficiency and renal disease of any character as shown by the numerous urinary examinations have to be excluded; the supply of oxygen to the blood is normal, and there is no evidence of retention of carbon dioxid. No sign points to an enterogenic toxicosis. Indoxyl-potassium-sulphate, though slightly increased on some occasions, never occurred in abnormal quantities, and acetone and ethyl-diacetic acid were at no time detected in the urine. None of the data obtained are symptomatic of an histogenic toxicosis. Uric acid, or any of the purin bodies, were not found in such quantities as to support the assumption of an abnormal nucleolysis; and anomalies of specific "internal secretions" could not be demonstrated.

A great number of disorders whose origin we cannot otherwise explain, we are of late very fond of ascribing to an autointoxication.

Like Furet, I interpreted narcolepsy as an autotoxic manifestation until I undertook the study of the present case. However, as not a single symptom pointing to any of the pertaining and known types of autointoxication could be detected, we have to conclude that there stands no autointoxication, at least none in the sense in which we commonly accept the term, at the foundation of this particular case of morbid somnolence.

The conclusion, moreover, is confirmed by the fact that the physical condition of the patient, besides the repeatedly mentioned anomalies, in no respect leaves anything to be desired.

It does by no means follow that the primary cause of this instance of pathological sleep is necessarily also the underlying factor in the production of any or all other cases of morbid somnolence. There is no doubt that many ectogenic as well as endogenic intoxications are inducers of abnormal sleep, and of sleeping seizures. There must, however, exist a class of cases closely related to the one before us which, while we cannot designate them as idiopathic, are certainly not attributable to any of the known intoxications.

While the urine exhibited less toxicity than is generally possessed by normal urine, and while it did not contain any abnormal substance, it served as the excretory means of an unusually large amount of chlorine.

The urinary chlorides represent the greater part of the chlorides derived from food and drink. A portion of the ingested chlorine, however, in the form of sodium chloride, is contained in sweat, tears, saliva, and fæces. The patient in twenty-four hours egested about as much chlorine in his urine as he had ingested with his seven liters of milk. In calculating the milk-chlorine I have made use of Bunge's (11) figures, but most naturally the composition of the best of milk varies within certain limits. If we now consider that the individual is afflicted with hyperchlorhydria—a condition in which, analogous to the normal state, the chlorine virtually occurs ecto-organically, and that he perspires more or less all the time, but very profusely prior to a narcoleptic seizure—we are forced to accept that for certain periods during the twenty-four hours the output of chlorides exceeds the supply, and that there exists a temporary deficit of chlorides in the blood.

In a certain respect this is a condition contrary to the one prevalent in acute febrile states and in many chronic disorders. This fact is readily understood when we recall that fever itself is nothing but an indication of accelerated or more intense vital processes, and that many chronic diseases are nothing else but the result of accelerated or otherwise perverted functions. The acceleration or greater intensity of any vital process, however, is dependent upon a corresponding increase of the osmotic tension. The moment the latter begins to decline, the reactive stage of the fever sets in. Large amounts of chlorides thus leave the organism by the kidneys and sweat glands and metabolism again approaches its normal degree.

Arising from the deficiency of chlorides in the blood there exists a relatively low osmotic pressure, as a consequence of the decreased ionization which we find for the time being diminished nutrition or stimulation of the nerve substance and therefore interference with its electrical conductivity. The sudden seizures of somnolence are explainable by the lowered nerve impulses conducted through the cells of the central system.

Diminution of osmotic tension, as it apparently prevails during the narcoleptic state, is by no means identical with an anemic condition of the central nervous system during that period, the contrary seems the case, that is, we have a hyperemia of the brain, as we very likely find it during the physiological sleep, and coincident therewith we meet with a lowered degree of osmotic pressure.

Neither undersupply nor oversupply of blood, as such appears to exert any influence upon the production of sleep seizures. These seem to be due, in the first instance, to diminished ionization of the chlorides in the blood—at least so in the case before us. Other instances of pathologic sleep may primarily depend upon the non-dissociation of other salts. The chlorides, however, appear to play the most important rôle in the osmotic tension of the body fluids, and their diminution or non-ionization calls forth various abnormal conditions, among which the affection just described is not by far the least interesting.

Fire Department Surgeons.—The Fire Chief of this borough has issued an order that the Fire Department surgeons shall go to all big fires so as to attend to injured firemen. The order was issued, it is stated, because on several occasions there was a conflict of authority between the ambulance surgeons and the firemen, in which the ambulance surgeons refused to carry out some of the orders given by the firemen. There are three surgeons in the Fire Department, one of whom must respond to every second-alarm fire and take with him the necessary dressings to treat the injuries the firemen may sustain. It is the surgeon's duty to order the injured man either to quarters or back on duty at the fire. When a fireman or a citizen is so severely injured at a fire that he requires hospital treatment an ambulance will be sent for.

ARE THE TONSILS TO BE REGARDED AS NORMAL PHYSIOLOGICAL ORGANS OF THE BODY?*

BY FRANCKE H. BOSWORTH, M.D.,
NEW YORK.

It is an ancient teaching, and one, I think, almost universally accepted both by the laity and by the profession, that the faucial tonsil constitutes one of the normal organs of the body in much the same sense that the liver and the kidneys do, and that it is endowed with certain important functions in the economy. It follows, therefore, that having important functions to perform, its absence or extirpation robs the system of those functions, with a resulting deleterious influence.

As to whether this teaching be a true one or not I do not intend to make a too positive statement; and yet it seems to me that there is ample ground for questioning this view, in that it oftentimes seriously hampers us in carrying out what seem to me to be clear clinical indications.

The anatomists tell us that the tonsil is an almond-shaped organ, situated between the two pillars of the fauces, and that its inner face is marked by from seven to twelve openings, which openings constitute the orifices of a similar number of lacunæ or blind ducts, the organ itself being covered by normal mucous membrane which extends down into the lacunæ. And yet the anatomists tell us that even this is not a constant condition, and that in a large proportion of infants nothing is found more than a small aggregation of lymphoid bodies containing no lacunæ, and lying beneath the mucous membrane. When we consider the extreme liability in child life to the involvement of the lymphatic bodies in hypertrophic changes, it seems fair to suggest that really the healthy tonsil may be the one above described, viz., one which consists of nothing more than a small aggregation of lymphoid bodies underlying healthy mucous membrane, and containing no lacunæ or blind ducts; and that the almond-shaped body usually described by anatomists is really a morbid growth.

The physiology of the tonsil has long been a subject of painstaking and laborious investigation, the problem being no nearer solution to-day than before. The same may, perhaps, be said of the whole lymphatic system, which, as we know, is found distributed extensively throughout the whole economy. Curiously enough, these lymphatics are found grouped rather extensively at that point of the human system where in the development of fetal life the hypoblast and the epiblast meet, viz., in the fauces, forming what is oftentimes called the lymphatic ring, and establishing four points where these bodies are aggregated in notable masses, viz., between the two pillars of the fauces, one on either side, forming what are called the faucial tonsils; in the vault of the pharynx, forming what is called Luschka's tonsil; and in the glosso-epiglottic fossæ at the root of the tongue, forming what is called the lingual tonsil.

Now, as we know, those masses between the faucial pillars have always figured in anatomy as forming normal anatomical and physiological organs of the body. Since the establishment of our specialty of laryngology, we occasionally meet somewhat vague descriptions of that mass of lymphatics in the vault of the pharynx, as constituting a normal anatomical and physiological organ of the body, under the name of Luschka's tonsil. These descriptions are very rare, very indefinite, and by no means constant in literature. I know of no anatomy or physiology which describes the masses at the root of the tongue in the same sense. Why this should be, it is difficult to say, for it seems to me it is a fair conclusion that the masses at the vault of the pharynx and root of the tongue possess claim to a position as normal organs equal to those masses between the faucial pillars. The only reason, perhaps, that can be given for the physiological dignity to which the faucial masses have attained, is that they are so much more prone to become the seat of diseased action, and were open to direct ocular inspection in this diseased condition, centuries before the others were recognized.

---

* Read before the New York State Medical Society 1901.

What the function of the lymphatics in the economy may be, I do not propose to discuss. It has always seemed to me, however, from a clinical point of view, that, considering the universality of their distribution, they were situated throughout the system for the purpose of arresting or retarding the encroachment of disease germs, thus acting, as it were, as a sort of police force; and considering, in the light of modern bacteriology, what enormous duties are imposed upon these little bodies, it seems easy to understand how much they are liable to suffer in the encounter; and especially is this true of those bodies between the faucial pillars, lying as they do in the sort of eddy which is established by these two muscular folds.

Whether this is the immediate cause of lymphatic hypertrophy I will not discuss, but the almost universality of a certain amount of lymphatic hypertrophy in some part of the body at every age is recognized by us all. That it should so frequently take the special form that it does in the faucial tonsil, viz., in forming deep lacunæ, I should regard to a certain degree as adventitious; but these crypts are by no means constant, as you know, even in hypertrophy of the tonsils. When they exist, we have an organ which lends itself admirably to what constitutes one of its principal activities, that is, as a trap for disease germs. It is difficult to understand why nature should place these sponge-like bodies in a normal throat. I think a far better and clearer understanding of clinical indications would be to regard this mass with its lacunar traps as a diseased body, for in support of this view it is not necessary to recount the very large number of infectious diseases which result from the mechanical entrapping of the disease germ in this sponge-like body. I think this teaching is notably emphasized by the numberless observations published in the last few years of the different germs found lodged in these filthy lacunæ.

Some twenty years ago, at a meeting in London, I made the observation in debate that practically there are no tonsils in a healthy throat. This observation was received with contemptuous jeers. After twenty years of additional clinical observation, I am disposed to repeat the same remark before the members of this society with a certain amount of curiosity as to how it may be received here. I do not wish to make the observation with absolute positiveness, and yet I repeat that it seems to me that if this view were more generally accepted it would make clearer the clinical indications in the treatment of many cases of throat disease. It would remove many supposed objections to operating upon the tonsils; and moreover, if such a thing were impressed upon the laity, we would meet with fewer objection to operations for extirpation of tonsils which are absolutely indicated by every clinical symptom. We so often meet with objections on the part of our patients: "The Lord put them there, and why should we remove them." I usually respond as the only answer to this: "The Lord never put them there, he had nothing to do with the matter; it is a diseased process which practically constitutes a morbid growth or tumor, and should be removed, and thoroughly removed, in the same manner as any other tumor, whether it be fibroid or malignant, or any other." We often hear as an objection to operating instances quoted of tonsils having been removed, and the throat left in a worse condition than before. I have met with many cases of this sort, and in all of them the subsequent symptoms were either due to some other cause, or the morbid tissue had been only partially removed. This question of thorough extirpation, I might say here (somewhat parenthetically), is one on which much emphasis should be laid, for I think it is a matter within the observation of all of us that a partial extirpation of a tonsil occasionally leaves the throat in as bad, if not in a worse, condition than before operation. Moreover, I am disposed to think that there is no other diseased condition met with in the fauces which gives rise to morbid symptoms in so large a proportion of cases as hypertrophy of these lymphatic bodies, between the faucial pillars.

I think, we have therefore some justice for advocating the view that the almond-shaped organ in the fauces, which the old anatomists called the tonsil, has not justified its claim to be considered one of the normal organs of the body, either on anatomical, physiological, or clinical grounds. I think that we may go still further, and say that it constitutes a distinct menace to the health and welfare of the body in the filthy lacunæ which make up its main bulk.

If it is a natural growth, rather than the result of a diseased process, then it seems to me that nature had been guilty of a crudeness of design which shows no analogy in the human economy, unless it be possibly in the vermiform appendix.

One word with reference to operative procedures. There has been considerable discussion of late as to the wisdom of selecting and using an anæsthetic. During the past thirty years I have invariably, in young children, insisted upon the use of a general anæsthetic, and my preference has always been for chloroform; the mode of procedure being briefly as follows:

The child being held in the lap of an assistant, the anæsthetic is administered until complete insensibility to pain is secured, the stage immediately before profound anæsthesia. One tonsil being removed, the child is thrown over on its stomach until bleeding ceases, when, after the administration of a few more whiffs of chloroform, the other mass is removed; the same process being gone through for the adenoid, which in so large a percentage of cases requires to be removed at the same time. The advantage of operating without profound anæsthesia, of course, is to retain a sufficient amount of reflex sensibility, whereby the supposed dangers of chloroform may be counteracted to a certain extent by the operative procedures in the throat. I desire to make here the broad and absolute statement that in several hundreds of operations which I have done in the last twenty-five years I have never in any instance observed the slightest symptom which would indicate any dangerous tendency or symptom from the use of chloroform anæsthesia.

As to the instrument to be used, I will say that for the last ten years I have ceased entirely to cut tonsils with a tonsillotome. No tonsillotome has ever been devised which will fit itself so completely over the growth as to thoroughly extirpate it in every instance. The cold wire snare adapts itself so admirably in every way to the operation that it seems to me it leaves nothing to be desired. The loop can be arranged in such shape and size as to fit perfectly over the mass, and can be applied between it and the lateral pillars in such manner as to ensure the thorough removal of the growth much more effectively than is possible with the use of the tonsillotome. Furthermore, if the tonsil mass is not enucleated at the first manipulation, it is a very simple matter to repeat until the lateral pillars drop into their normal position. The danger of hemorrhage, as I have always claimed, does not present, especially in operating on children, but in operations on adults a very considerable hemorrhage, which may even reach the dangerous stage, is always to be anticipated when the knife is used. With the snare this danger is practically eliminated, and to one who has met with severe hemorrhage after tonsillotomy, this is no slight consideration.

[illegible] Avenue.

A Case of Dermatitis Gangrænosa.—The case is reported by J. M. [illegible], his patient being a boy two years and nine months old, suffering from a number of punched-out circular sores on the face and hairy scalp, and a few similar though larger ulcers on the back of the wrists and nates, and some smaller ones on the genitals. The sores were covered when first seen with a greenish-yellow pus, and in one or two only was the pus raised above the edge of the ulcer. After the application of a creolin poultice, the floor of the sores was quite clean and of a deep red color, with the edges sharply cut, of a similar red color, which was strictly limited to its immediate neighborhood. No bullæ were present at any time. The size of the sores varied from the size of a threepenny piece to half a crown, the greatest number being about the size of a shilling. Two on the back of the right hand—one over the wrist, and the other over the metacarpo-phalangeal joint of the index finger—were each about the size of a two-shilling piece, while a solitary ulcer over the right trochanter was still larger. Most of the ulcers were discrete, although a very narrow strip of healthy skin intervened; but on the forehead, above the right eye, on the right cheek, and on the left eyelid two adjoining ulcers coalesced, forming an irregular gyrate outline made of two circles meeting. The eyelids were enormously swollen and adherent from the discharge which exuded from between them, and could not be opened so as to examine the eyes. The lips and margin of the alæ nasi were also sore and ulcerated, with considerable tumefaction. The ulcers did not seem to be very painful or very irritable, as, with the exception of those about the mouth, they were not scratched or rubbed by the little patient. The lower limbs were covered with an ill-defined rash, not unlike the staining of measles. The limbs were greatly emaciated, and the skin was rough and loose. The child, when admitted, was very weak and prostrate—not able to turn from side to side. He was greatly emaciated and had a cough; no physical signs of lung disease were, however, discoverable. The treatment consisted in giving as much nourishment as could be taken, and of washing with creolin, applying boric-acid poultices, dusting the sores with iodoform, and applying a weak ichthyol and lanoline ointment to the eyes. No improvement followed, for although no more spots appeared, and no pus was discharged, there was no evidence of healing, while the skin surrounding the sores on the wrist and hip became of a deeper and more purplish color. Death occurred five days after admission to the hospital.—*Dublin Journal of Medical Science.*

Certain Factors Influencing the Death Rate from Consumption.—John Marshall French gives an exhaustive review of the subject. Infection, whether by hereditary transmission, inoculation, or ingestion, is one most important factor. As to age the greatest liability to the disease lies between twenty and thirty years, the least between two and fifteen. There is a slight excess of female deaths, due probably to indoor life or lack of exercise. No race or nation is immune. Indians and Negroes in America are especially subject to consumption. In America, the Irish furnish more than their normal proportion of deaths from this disease. As to climatic conditions, a moderately high altitude with dry air and [illegible] tends to lower the death rate from consumption, while the opposite conditions tend to increase it. Statistics show that the mortality from consumption increases as the density of the population increases. In regard to heredity, the influence of acquired predisposition outweighs that of hereditary predisposition, and a combination of both will further increase the liability. The physique, or build, is a more important factor in the death rate than either family history or previous illness. Occupations furnishing outdoor employment, fresh air, and exercise lessen the death rate, while those involving indoor life, exposure to irritating dust and noxious vapors, restricted and confined muscular movements, the frequent use of certain muscles, and alcoholism increase it. Statistics show that the death rate from consumption is steadily decreasing throughout the civilized world, a decrease coincident with better circumstances on the part of the people, increased intelligence of the masses, and the general progress of civilization.—*The Medical Examiner and Practitioner.*

The Relation of Interstitial Nephritis to the Heart.—H. N. Leavell says that the cardio-vascular changes occurring in this form of Bright's disease may be summed up in two words: Sclerosis of the arteries and hypertrophy of the heart. As a result of the renal lesion and consequent imperfect depuration of the blood, or conditions which coexist although not necessarily the outcome of the renal changes, an abnormally high vascular tension becomes established. Sooner or later the walls of the arterioles become thickened and inelastic, resisting the onward passage of blood, thus imposing an additional burden on the left ventricle, which undergoes hypertrophy successfully to cope with the high peripheral resistance. Up to a certain point the inevitable hypertrophy of the heart is compensatory or an "accommodation enlargement," and is fortuitous, so long as it compensates the renal lesion its purposes are good. The arterial changes are progressive and the increased blood-pressure permanent. The hypertrophied muscular tissue is prone to degenerative changes, shows a greater tendency to exhaustion and weakness than the normal heart tissues, and it is but a question of time until increasing impairment of nutrition of the myocardium, with constantly growing peripheral resistance, results in failure of compensation and dilatation of the hypertrophied ventricles. This adjustment of the cardio-vascular system to the renal lesion tends to obviate the main danger—the retention of uræmic toxins. The debt which the kidneys owe the heart is amply demonstrated when cardiac compensation fails, and the greatly diminished quantity of urine, increasing albuminuria, and rapidly developing uræmia leave no doubt as to what organ has conserved the patient's life. Kidneys which may do well under increased blood-pressure prove miserably inadequate when such support is removed. Therefore it may be stated that the condition of the heart is the best gauge of the disease.—*American Practitioner and News.*

A New Process of Nephropexy.—Niccola Giannettasio describes his process of nephropexy for the relief of floating kidney, which consists of three steps: (1) Detachment of the kidney, and formation of a rectangular flap from its capsule. (2) The making of a buttonhole in the quadratus lumborum by the separation of a small bunch of its marginal fibers, and the drawing of the flap through this opening. The muscular band will be between the flap and the denuded renal parenchyma. (3) Fixation by suture of the three free edges of the flap to the corresponding edges of the capsule, including in the suture some of the parenchyma of the gland.—*La Riforma Medica.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, January 11, 1902.

NATIONAL PUBLIC HEALTH LEGISLATION.

WITH the assembling of Congress, the agitation in favor of legislation creating a permanent public health department in the general government has been renewed, and the result will, in some measure, be influenced by medical opinion. It is desirable, therefore, that the present state of the questions at issue should be understood in order that these members of the profession who are interested in the subject may act wisely. It too frequently happens in efforts to secure legislation that the parties personally engaged become such strong partisans that in their zeal they fail to recognize opportunities when conciliation would be in the interest of the public welfare. It is a question worthy of the serious consideration of all interested in creating a competent public health department at Washington, whether the agitation has not reached a stage when an agreement might be arrived at upon a single measure which would comprise all that is essential in the organization of this public health service. We are impressed with this view on reading the address of Dr. Stephen Smith before the American Public Health Association, in which he gives the history of the efforts to secure the creation of a department of health. Taking these facts with the later and present attempts to accomplish this purpose, it is not difficult to understand the present situation.

The ultimate purpose of all interested in this legislation is and has been the same, and they have differed only in their methods of accomplishing it. That purpose is the creation of the department of health, the chief officer of which should finally become a member of the Cabinet. One party has proposed to approach this final result by progressive steps, while the other has been more radical, and has attempted to reach the same end by one decisive step. The former party adopted the Marine Hospital Service as the initial organization, and has steadily sought to increase its health powers and duties; the other has introduced various bills into Congress, one creating a board of health, a second making a secretary of health, a third a commission of health, a fourth a commissioner of health, etc. The result of all these efforts, as summarized in the address referred to, shows that the Marine Hospital Service has steadily advanced along the lines laid down by its promoters, until it has become in fact, though not in name and in the proper adjustment of its service, the central health authority of the country. On the other hand, the efforts to create outright, by a single measure, the desired department of health or any organization approaching it, has proved a failure, except during the great yellow-fever epidemic when the National Board of Health was created, which had a short-lived existence, only to be succeeded by the Marine Hospital Service. The bills now before Congress are drawn on the old lines, one class being for advancing the Marine Hospital Service nearer to the position of our National health authority, and the other to create a new and fully equipped health organization. The question which interests the profession is, How long shall this fruitless contest be continued? For our own part we believe the time has come when wiser councils should prevail and harmony should be sought by an effort to reconcile differences of opinion which relate only to the method of procedure to accomplish a given result. Actuated by a desire to unite the profession and all persons interested in sanitary reform on a single practicable plan, we urge those who are engaged in promoting the passage of bills before the present Congress to confer together at this early day in a spirit of conciliation, and unite on a common measure.

To this end we suggest that special consideration be given to a bill recently introduced into the Senate, entitled "A Bill to Increase the Efficiency and Change the Name of the Marine Hospital Service." The important features of this bill are as follows: The name proposed is "The United States Health Service;" the officers are to be the present officers of the Marine Hospital Service, the chief officer being called the Surgeon-General; an advisory board is provided for the hygienic laboratory consisting of the surgeons-general of the army and navy, the chief of the bureau of animal industry, the director of said laboratory, and five experts in laboratory work selected by the surgeon-general of the service, and appointed by the Secretary of the Treasury; a chemist, a medical zoologist, and a pharmacologist are to be appointed by the President to have charge of the divisions, respectively, of chemistry, zoology, and pharmacology of the hygienic laboratory.

Provision is made for a conference with the State and Territorial boards of health or health authorities, including the District of Columbia; finally, a scheme for uniformity in the registration of mortality, morbidity, and vital statistics is proposed. In a word, if this bill were passed without any change, we should have a United States health service having for its head a thoroughly qualified medical officer appointed by the President; a large corps of skilled medical sanitary inspectors, now serving in home quarantines, in centers of infection, and in all important foreign ports; a laboratory equipped for exhaustive scientific investigation managed by a board of chosen experts; provision for needful conferences of the health authorities of the States and Territories with the United States Health Service; provision, finally, for uniformity of registration of vital statistics. This would be but one step removed from a department of health, with its secretary.

It is not claimed that this is a perfect bill, but it must be admitted that it contains nearly every provision for which those who are seeking to create a public health service in the general government have contended. For this reason we believe it furnishes an admirable basis for the consideration of a conference of all parties interested in the health bills now before Congress.

IONIZATION AND SOME RECENT VIEWS THEREON.

"Life," says Herbert Spencer, "is adjustment to our environment, and as is the degree of life, so is the degree of adjustment."

In the lay press we read some remarkable reports of discoveries of Professors Loeb and Mathews, of Chicago. These observers are said to have solved several of the predominant physiological problems of life, and would seem, having regard to the reports, to have afforded us a new adjustment of our environment, even to the extent according to an enthusiastic reporter of "indefinitely postponing death."

Hardly less startling also is the announcement "that electricity is the basis of life."

But at this point let us say at once that we entirely absolve the distinguished professors from holding any such views as we have above presented. Their serious contributions to physiological discovery and research entitle them to a most respectful hearing, and we shall await with interest the actual text of the papers they have recently read, and which have been alluded to only in a fragmentary and evidently distorted manner by the daily press. Yet enough has been put forward to entitle us, perhaps, to a few words of comment. Stated briefly, it would appear that the energy of food stuffs and of certain solutions of inorganic salts, which physicians would term medicines, is due to the electrical charges of free ions which are a constituent part of the solutions used as food or medicines.

A brief quotation will, perhaps, best put a part of the new claims most fairly before our readers. We quote:

> "Professor Mathews' paper was a sequel to the one of Professor Loeb. The latter declared that his experiments had proved that muscular contraction and all the vital processes of life were not due to the mechanical heat generated by food, but by the presence of electric-charged atoms and clusters of atoms contained in the food. Professor Mathews declared that he had pursued the same methods in experimenting on nerves and had reached the same results.
>
> "The experiments revealed the fact that certain salts are alone poisonous, and that these poisonous effects are abolished only when a salt containing the opposite properties is employed to neutralize the poisonous salt. Some salts contain electro-positive charges, and others contain electro-negative charges.
>
> "The proper adjustment of the two charges, when they neutralize each other, gives the electric charge that is the vital thing in all vital properties. Professor Mathews declared in conclusion that the negatively charged molecules are those which stimulate activity, while the positive charged are those which hinder contraction."
>
> "Dr. Loeb has, in fact, continued his experiments seeking to determine the true nature of death. He has concluded that it is not a cessation of action but a morphological process, and in the case of the sea-urchin eggs in recent experiments has indefinitely postponed death by the use of potassium-cyanide solutions. He is now experimenting in connection with Dr. Mathews in the logical continuance of this experiment."

That we may preserve our mental equilibrium while reading the statements as presented, we may for a moment, and most briefly, refer to the "prior state of the art," so to speak, namely, to what was accepted scientific theory and fact antecedent to the revelations from Chicago.

The theory of ions began with Faraday. The free ion having an electrical charge was assumed by Clausius as at least having temporary existence, and was, later on, considered by von Helmholtz to be essential to electrolytic conduction and electrolysis. But the true idea of our present conception was presented to us by Arrhenius and now constitutes a good working basis to explain electrolysis. In this modern sense an electrolytic solution is one in which an electrolytic dissociation or ionization exists.

On the basis of the early conceptions of the ion and its electric charge, positive or negative, arose the electro-chemical theory of Davy and of Berzelius, wherein chemical affinity is due to the electrical property of the ion.

The theory of Arrhenius infers for every solution which is a conductor of electricity, an extensive and inherent dissociation of all or part of its molecules into free ions, each bearing a positive or negative electric charge, and, within limits, the more dilute the solution the greater the number of free ions, and the better the conductivity to electricity. Again, the special properties of a solution are due to the free ions, which it contains.

For instance, chloride of sodium dissociates into free chlorine ions and into free sodium ions; so, also, hydrochloric acid dissociates into free hydrogen ions and into free chlorine ions. Both solutions are similar in so far as they contain chlorine ions, but owe their great difference respectively to the hydrogen ion or to the sodium ion. Or, to consider alone chloride of sodium, the physiological properties of common salt are not due to molecules of chloride of sodium, but to free ions of chlorine and free ions of sodium, each charged respectively with negative and positive electricity. To the ion and its electric charge, therefore, we must look for the special quality, medicinal or otherwise, which a given solution possesses. Furthermore, the properties of a given solution are due mainly to one or the other of its free ions. It has been demonstrated, for instance, that the hydrargyrum ion of $HgCl_2$, in antiseptic solutions, is the germicidal ion, and that the sour taste of acid solutions, like hydrochloric acid, is due to the hydrogen ion, and so on. Here we have a comparatively new therapeutic conception of the cause of the activity of certain solutions common to medicine and used either therapeutically or for physiological experiment.

If we turn from the agency employed to the tissue to be affected, the same conception of ionization holds good. The proteids of the animal economy are found to consist of protoplasm, in combination with inorganic salts, and individual ion proteid compounds exhibit their characteristics just as does the hydrogen ion in acid solutions or the hydrargyrum ion in solutions of bichloride of mercury.

Assuming that some of the phenomena of life depend, among other things, upon the combination of certain free ions like those of sodium, potassium, calcium, and others with proteids, Professor Loeb has said, employ but one free ion compound to affect muscle fiber, a solution of common salt for instance, and the result will be toxic to the tissue. This proved to be true, and to be equally true that the toxicity could be removed by again supplying solutions of potassium or of calcium. In other words, when the proteid was submited to the sodium solution alone, the latter acted toxically because the sodium ions replaced the potassium and calcium ions and altered deleteriously the physical integrity of the tissue.

It is thus far evident that when ion meets ion a reaction occurs. From this point onward, the present reports from Chicago would appear to indicate that the investigators referred to had taken a great stride. And after reading the statements it would seem that we must formulate the new proposition somewhat after this fashion. Administer to the patient, or apply to the physiological preparation, a solution whose quality depends upon certain free ions electrically charged, and the *electric charges* of these free ions will in turn modify the electric charges of the free ions which are an essential constituent of the patient's or the preparation's proteids. Such, at least, is the interpretation we put upon the reports as they reach us.

Now, some people would be old-fashioned enough to term the above proposition as a chemical rather than an electrical reaction, for the electric charge of the ion has long been predicated under the name of the elektron, and has given rise, as we have mentioned, to the hypothesis that all chemical affinity is electrical in its nature. In short, are not the reactions termed in these reports electrical, reactions which we have hitherto termed chemical? So far as we have been enlightened, we should feel inclined to think that we were greeting an old friend in a new garment.

Meanwhile we await further advices, and are perfectly willing to believe, not alone that old facts have received a new and a perfectly justifiable interpretation in the hands of the skilful and learned professors, but also that physiological phenomena, hitherto obscure, have emerged from their obscurity in the light of their new researches. And, in any event, we welcome the theory of ionization as a conception which in its practical applications to the problems of medicine will undoubtedly clear up many an obscure point as it has already done in physiology and chemistry. Indeed, it is not improbable that this doctrine holds forth the greatest hope yet in our possession for an intelligent and broadened twentieth-century therapeutics.

EFFICIENT VACCINATION.

Smallpox has been peculiarly rife in many parts of the United States during the past three years. With the exception of a comparatively small section of the population, vaccination is esteemed a more or less sure safeguard against contracting the disease, as well as a means of abating its virulence when contracted.

Those who oppose vaccination, although perhaps animated by good motives, do so either through ignorance of its merits, or because they are prejudiced against it, on account of some accidents which have occurred, owing to the use of impure vaccine, and careless methods of performing the operation.

Dr. Monckton Copeman, the originator of glycerinated calf lymph, and a recognized authority on all in connection with vaccination, read before the Medical and Chirurgical Society of Great Britain a paper dealing with the minutiæ of the method.

Dr. Copeman gives some useful hints as to what constitutes efficient vaccination, and describes the measures to be taken to ensure this result. Efficient vaccination, he says, may be summarized as the clinical activity and bacteriological purity of the lymph employed for vaccination; the skilful performance of the operation itself; the making of an adequate number of insertions of lymph over a sufficient area; the observance of precautions needful for ensuring strict asepsis, both at the time of vaccination and subsequently, until the vaccination wounds are soundly healed.

Taking these points in detail, Dr. Copeman says: "Although lymph may retain its potency for weeks or months, yet, through various causes, it may quickly become inert; it is therefore advisable that the lymph should be employed for vaccination as soon as possible after bacteriological examination has demonstrated its freedom from suppurative and other extraneous microorganisms. Respecting the number of insertions, the last British Commission on Vaccination concluded that probably the least extent of vasciculation absorption, which is capable of affording adequate protection against subsequent invasion by smallpox, is an area of half a square inch.

The p ecautions recommended for insuring strict asepsis are many Dr. Copeman thinks that bathing with a warm solution of boric acid before and after the operation is the most generally useful procedure.

Protective measures advised by Dr. Copeman during the maturation of the vesicles are for the first few days a shield over the wound, and during the second week some dressing of an absorbent nature, and free use beneath of a dusting powder of boric acid.

The technique of the operation is thus described: Instrument, the ordinary triangular-headed surgical needle. The manner of operating, which affords the most generally successful results, consists in blowing out the lymph from the capillary tube in which it is stored on to the surface of the skin at different points, the number and situation of which must correspond with those of the vesicles which it is desired to obtain. The skin put slightly on the stretch is then gently scarified, through each droplet of lymph, with the needle first in one direction, and another more or less at right angles to the first, the drawing of blood being avoided as far as possible.

Statistics gathered in Great Britain show that an appreciable advantage to the community has resulted from the adoption of modern methods of vaccination.

A valuable paper concludes with the author's view as to the relationship of vaccinia to smallpox, which is that the former is an attenuated form of the latter. Experiments undertaken by Dr. Copeman have strengthened this belief.

The feature of the paper is undoubtedly Dr. Copeman's remarks as to the probable deterioration of the glycerinated lymph if not used when absolutely fresh. It would appear to be the opinion of some physicians that glycerinated vaccine will retain its virtue for an almost unlimited period. Acting upon this belief has perhaps been the cause of much unsuccessful vaccination.

The area of vasciculation absorption is another point which is worthy of consideration. Many vaccinators are in the habit of making no more than [illegible] at the most three insertions, but if the recommendations of the British Commission are to be considered as founded on correct premises, at least four insertions will be required—the reason given being that experience has shown that less inflammatory reaction and less permanent destruction of skin tissue are likely to ensue than if the attempt be made to secure an area of half a square inch by means of a less number of insertions of lymph.

If modern methods of vaccination be conducted on the lines laid down by Dr Copeman it is claimed that, while providing immunity to smallpox, at the same time there will be no fear of the accidental transference of erysipelas or other diseases.

THE DOCTOR AS A SPECULATOR

THE poor business qualifications of the ordinary doctor are proverbial. Hard as his struggle is to provide for himself and family, he usually gets only half what he earns, the remainder being charged on his books as uncollectable fees. His work is honestly and conscientiously done, but when the time for recompense comes he is usually forgotten by his former grateful patients. This condition is explained, in part, by his want of promptness and regularity in reminding his clients of their indebtedness. In this respect the physician is different from any other man who does business on business principles. His patrons conclude that he is the only one of their creditors who does not need money, as all others persist in asking for it when it is due. Hence the longer the account stands the less likelihood there is of its being settled.

From such points of view it is easy to understand why the poor doctor is generally in debt and is ever eager to make money in other ways. Speculators, promoters, stock jobbers, and the like understand this so well that the confiding medical man becomes a willing victim to their swindling schemes. The latter are not exposed for the reason that no complainant wishes to advertise himself as having been duped. Although one lesson is generally enough for each individual, it takes a great while to make such an education widely distributive and permanently effective.

It is strange, but nevertheless true that there is more stock jobbing among physicians than with any other class of professional men. And it is equally conceded that they can least afford to risk their hard-earned incomes in that way.

During the recent flurry in Wall Street it has been said on reliable authority that the medical profession sunk enough money on margins to endow a hospital or place the Society for the Relief of the Widows and Orphans of Medical Men on the soundest possible footing. In one instance it was said that a medical man who had the so called "nerve to hold on" during a sudden drop in values, not only lost his little fortune, but his home besides.

Now the craze seems to be for mining and oil stocks with impossible dividends. Even some respectable medical journals lend their advertising columns to the exploiting of these and other questionable schemes. The moral of it all is that the medical man who wishes to save his money and provide for his family should have nothing to do with any business he does not thoroughly understand, and least of all should he speculate in any stock for the real value of which he must depend on the mere statement of others. Even stocks in medical journals are not beyond the danger of depreciation while taking the ordinary business chances of earning interest on par value. So also with other plans for becoming rapidly rich, and for obtaining large dividends from small but pretentiously alluring investments. In view of these facts it seems incumbent upon us to guard the doctor against the constant temptation to go out of his beaten track for making his money. In the long run with his slow accumulation of funds the best investment is a life insurance policy, which will at least spare his widow and orphans from seeking charity or possibly bowing to menial labor. The great thing is to be contented with small profits, and have them permanent and sure. This sound business principle appeals to the doctor with special and ofttimes with mournful force.

PHTHISIOPHOBIA

PHTHISIOPHOBIA, so aptly named in the paper of Dr Knopf, is just now liable to assume epidemic proportions. While the senseless scare lasts the consumptive has a poor chance for decent harbor or proper treatment. The sick immigrant is not only prevented from landing on our shore, but the native is forbidden to take his chances in health resorts. He must in many quarters not only be treated as an outcast, but allowed to die like one. All this is the result of the inordinate zeal of some health officials whose duties appear to consist in senselessly alarming the public on the alleged dangerously contagious character of the malady. It is sad to know how great a fire can be started by insignificant sparks. In the interests of humanity and fair play to a large class of helpless sufferers, it is high time that Knopf and others should have opportunity for voicing general professional sentiment on the subject. The MEDICAL RECORD long ago held similar views to those expressed in the Academy's discussion, but only very lately have they been generally indorsed.

THE PROPOSED EMERGENCY RATION.

The annual report of the Commissary General of the Army contains a report relative to a proposed emergency ration, in the preparation and trial of which a board of officers has for some time been engaged.

Briefly, the board announced that the military emergency ration should be the smallest nutritive equivalent, which would maintain the soldier for one day without serious impairment of vigor, and with the repetition of the same ration for a period not exceeding four days. The main objective in the ration was the maximum food value in the minimum space and weight. The components of the ration were to be selected with reference to wholesomeness and proper nutritive value, and the portability of the ration as a whole. Acceptability as to taste and the keeping qualities of the articles selected were also to be taken into consideration. The ration should also be capable of being made into a hot soup or stew or of being eaten cold, dry, or mixed with water. Finally, the size, weight, and form of package was to receive consideration.

The board examined and tested various articles of food submitted to it as being suited for use as an emergency ration, but regarded none of them as fulfilling the requirements of the latter. It, therefore compounded a ration of its own, consisting of four ounces of evaporated beef, eight ounces of parched wheat, seasoned with one ounce of salt and a little pepper. The other components of the ration consisted of two ounces of chocolate and two ounces of sugar. The whole ration weighs seventeen ounces, occupies twenty-five cubic inches of space, is said to contain less than 6 per cent. of water, and has a food value of 1,955 calories. The preparation of 2,000 of these rations was authorized, and the board was directed to proceed to army posts in the Indian Territory, for the purpose of practically testing this ration and the several others submitted for trial by outside parties.

In the first test of the board's ration, it was stated that every man was in as good condition at the end of the trial as if ordinary rations were used. The net loss of weight of the thirty-four men subsisting on the ration was seven and one-half pounds. At the conclusion of the trial of the so-called "standard emergency ration," made in New Jersey, the twenty-eight men composing the detachment were found to have lost 144 pounds in weight. Strength was also lost, and the board was of the opinion that five days was the longest period during which this ration could be used without being supplemented by other food. A ration presented by a leading packing firm was next tried, but the report states that nearly every one subsisting on the ration suffered excessively from hunger, and a number of the men became so demoralized as not to observe the order to eat no food other than the ration. Some of the men were reduced to a pitiable state of weakness, and it was necessary to put eight of them on full army rations before the test was concluded. This ration also had the added defect of requiring cooking before use.

A second trial of the board's ration was then made to ascertain what condition for service a cavalry command would be in after subsisting upon it for five days. The route was so laid as to make the daily march about twenty miles in length. Instead of making camp before the midday meal, a halt was made about noon for luncheon, the meal consisting of the ration as it came dry from the can, washed down with water from the canteen. Camp was made some time during the afternoon, all necessary work being completed before the evening meal was served. The actual loss of weight of the fifty-six men composing the detachment subsisting on the ration was six pounds.

The result of this trial was to confirm the members of the board in the favorable opinion previously formed of the ration devised by them. It is stated that at no time during the trip was there the slightest indication in the appearance of any man that he was suffering from hunger or weakness, and no men were treated for illness that could be attributed to the ration. This was a much more severe test than any of the rations had been subjected to during the first set of trials, and the results were stated to be so favorable that the board felt warranted in asserting that any command can go into campaign and subsist exclusively on this ration for ten or more days at a time, with the absolute assurance of being fit for service at all times.

In the opinion of the board, the ration formulated by it fulfils all the requirements of an emergency ration. The practical tests have shown that it is capable of keeping up the full muscular strength and endurance of the soldier for a number of days, with no suffering from hunger, and but a trifling loss of weight. The board, therefore, recommended its ration for adoption and issue as the United States Army emergency ration.

Sanatoria for Consumptives.

There has been within the past few years, and particularly during the year just gone by, a remarkable spontaneity of giving among the millionaires of this country. The men who are rich beyond the dreams of avarice seem to have awakened somewhat suddenly to a conception of the fact that with the possession of an overflowing supply of this world's goods, they have also come into a corresponding degree of responsibility.

Andrew Carnegie's example has had much influence in arousing the charitable instincts of his fellow millionaires, and the consequence has been that money has flowed like water to improve the physical and mental welfare of the masses, and to advance the cause of science.

Great Britain, up to the present time, has lagged in the race of thus benefiting its sick and poor inhabitants, and of solving important scientific problems.

Prominent exceptions among the many wealthy men of that country have occurred; but, on the whole, the opulent British philanthropists do not compare favorably with those of the United States.

The news, however, has been recently received that a rich Londoner has donated $1,000,000 to be applied to whatever object King Edward might deem most fitting. The King's choice has fallen upon the treatment of consumption, and the greater part of the large sum will be devoted to the erection and equipment of a sanatorium for the use of indigent persons suffering from that disease.

No better decision could have been arrived at and the scheme may be commended as worthy of adoption by our plutocrats and municipal authorities.

In the meantime, equally active interest is taken in such humanitarian schemes in this country. The site for a State sanatorium for New York has been secured, and Governor Odell has recommended the establishment of similar institutions in different districts of the commonwealth. Pennsylvania has followed suit in a projected cottage plant at White Haven. Coincidentally, also, Dr. H. P. Loomis, in the discussion of the subject before the Academy of Medicine, has advocated a special hospital on Ward's Island for the care of the pauper consumptives of the city. All these movements are in the right direction. and deserve every encouragement.

For the Relief of Acting Assistant Surgeons.

A bill for the relief of acting assistant surgeons, United States Army (H. R. 7269) has recently been introduced into Congress. After reciting the disabilities imposed on this class of worthy medical men under existing laws decisions, and regulations, the bill states its purpose of relieving "such unjust discrimination and to give a proper recognition to their patriotism, services, hardships, and exposures, as well as to give the pay and emoluments due them under the provisions of their contracts." The bill provides for the granting to contract surgeons, under proper authority, of leaves of absence, either sick or ordinary, on full pay, and entitles contract surgeons to commutation of quarters and all the other rights, privileges, and emoluments which attach to commissioned officers of the grade of first lieutenant of the army. The bill is also retroactive as regards the payment of just claims for pay withheld by the Treasury for sick or ordinary leaves and for commutation of quarters. It gives the preference to contract surgeons for appointment to the various medical branches of the Government, other things being equal, over such applicants as have not had previous military service; and provides that all acting assistant surgeons, who have served since May, 1898, as who may be given warrants in the [illegible] and be commissioned as such by the President. The bill grants two months' extra pay, as given by Congress to the medical officers of volunteers who served during the war with Spain, to such contract surgeons as have served outside the limits of the United States. Finally, the bill grants the privileges of the Soldiers' [illegible] [illegible] as officers of the regular and volunteer armies.

This measure asks only for proper recognition of the services of a deserving class of medical men, and a grading equal to that granted to commissioned officers of the grade in which contract surgeons [illegible] [illegible]. As such, it should receive favorable consideration at the hands of Congress.

INTER-STATE RECIPROCITY

The most important question now impending in the American medical world is that of reciprocity. Uniform medical legislation is bound up with reciprocity. One is impossible without the other, or rather it should be said that it would be in a high degree injudicious and unwise to give reciprocity, and not first to make an equality of standards for admission to the study and practice of medicine.

The prime movement, therefore, in the direction of reciprocity must be a uniform medical legislation. The committee on organization of the American Medical Association in its preliminary report has fully recognized this fact, and at the annual meeting of the association next summer the subject will be discussed in all its bearings, and a decision will be probably reached.

Dr. B. D. Harrison of Sault Ste. Marie, secretary of the Michigan State Board of Registration in Medicine, speaking recently on medical reciprocity said, "We are working for reciprocity now, and urged that some basis for reciprocity be established." He then proceeded to say, "There will be a meeting some time in January, I think, at Chicago, of the executive officers of the State boards of medical registration from Wisconsin, Illinois, Indiana, Ohio, and Michigan. We are trying to form a nucleus of West Central States first. All the States recognize the necessity for it. The Michigan law, which has been in effect for two years, provides for reciprocity, admitting such physicians from other States as are considered qualified. There will be necessarily a new law or an amendment covering the matter of matriculation.

"At present there is some difficulty between the colleges in the State over matriculation of applicants. Some of the colleges complain that an applicant turned down by one college is allowed to matriculate at another. This can be obviated by having the matriculation lists filed with the State Board to be passed on."

The plan which Dr. Harrison says the State boards of the West Central States are endeavoring to adopt, that of forming a nucleus of a few States at first, was suggested some time ago by Dr. Emil Amberg of Detroit and commented upon in the MEDICAL RECORD.

A beginning must be made, and while changes in medical laws will have to come gradually, it is plain that any scheme would be preferable to the confused and incongruous system now in vogue.

The matriculation of candidates is another stumbling block to those who endeavor to raise the standard of medical education. As Dr. William Warren Potter of Buffalo has well said, "There must be an equalization of the preliminary requirements of medical students and a uniformity of applying the tests, a uniform period of collegiate training, including uniformity of methods of teaching, and finally an absolute similarity as the method of conducting state examinations and granting licenses."

In short, there must be uniformity in every step toward the degree that the would-be doctor takes, and the preliminary examinations should be of as relatively high order as are the professional examinations.

Dr. Harrison's suggestion that the matriculation lists be filed with the State Board to be passed upon should have the desired effect of [illegible] [illegible] of matriculations of a uniform character.

The MEDICAL RECORD has for some time past expressed the opinion that no medical degree ought to be conferred unless the candidate for such has undergone a four years' course of study, and that the final examination shall be undertaken by an independent and unbiased board.

The establishment of a high uniform standard of medical education throughout the country would be an incalculable good to the medical profession in every way, and while it is not to be expected that so sweeping a change will come quickly or without a great deal of opposition, yet the signs of the times would seem to point to alterations of a radical kind in medical legislation.

Whatever happens, however, it is left to the medical profession to work out its own salvation.

SMOKE IN LONDON

While the inhabitants of New York for a few weeks have been contending with the inconveniences and danger to health of dirty streets, its sister city across the Atlantic has for generations suffered from a far worse infliction.

Kipling, when he wrote of the "City of Dreadful Night," might have had in his mind London in the winter season, during one of those dense fogs which appear to be more or less peculiar to that vast center of population.

Patriotic cockneys, jealous of their birthplace's fair fame, deride the idea that these fogs are injurious to health, and some go so far as to declare that they are invigorating and exhilarating, and as a tonic to the system are preferable to a breeze from the sea.

Of course such well-meaning citizens delude themselves, for proof has been forthcoming on many occasions that fogs are followed by an increased death rate.

During the past month, London has been visited with some especially bad fogs, and again scientists and sanitarians are discussing means to prevent, or at least to mitigate, the severity of these visitations.

Sir William Broadbent recently delivered himself of some wise remarks upon the matter considered from the point of view of health. He pointed out that the two great gifts of nature which made for long life were air and light, and the coal smoke of London polluted the one and intercepted the other, thus producing a deteriorating influence on the health and vitality of the community. Fortunately there was a mechanism which to a great extent intercepted coal smoke on its way to the lungs, but every one who lived in London must have his lungs speckled by it. Walking in a city in which the air is generally so permeated with smoke and other substances as to be gloomy, if not actually dark, does not exert the beneficial effects of that form of exercise taken in the country.

The lack of the stimulating influence of light and air, said Sir William Broadbent, was steadily injuring the health of the community.

The continued presence of smuts in one's room had an unfavorable effect on the temper, which reacted on the health. There could be no doubt that whatever tended to the purification of the atmosphere of London would tend to preserve not only the health, but the happiness of its inhabitants.

New York suffers from an atmosphere vitiated by foreign substances to a very much less extent than does London, but she has had experience enough of the soft-coal nuisance to be able to sympathize with the latter city in her troubles. The only radical cure for London fogs is not to burn soft coal, which in the present juncture of affairs is said to be a remedy impossible strictly to enforce.

Laws, however, might be enacted compelling persons, and particularly large manufacturers, to adopt measures by which furnaces and stoves would consume their own smoke.

Antiquity of the Temperance Reform.

The *Sanitarian* for December has an article copied from the *Chicago Israelite* on the above subject.

Any one who is acquainted with the old Testament will know that wine-bibbing is there strongly condemned.

The *Chicago Israelite*, however, states that the Israelites were not the first people to produce illustrious advocates of abstinence from wine. Long before the birth of Solomon, warnings against intemperance were common in the literature and laws of China. In the year 2285 B.C. a man was banished by the emperor because he had invented an alcoholic drink from rice. In 2205 B.C. the Emperor Yu refused to drink wine, for he said, "In after ages there will be those who through wine will lose their kingdoms."

Un Wang the next emperor, punished drunkenness by death. In 206 B.C. the penalty for that offense was a fine instead of death. After many changes in the laws regulating the sale of drink and the punishment of drunkards, in 1279 B.C. all liquor makers were banished from China.

After the Chinese in point of time came the Jews. After them the Hindoos.

The ancient laws of Ceylon, Burmah, and other Buddhist countries forbade the manufacture, sale, or use of liquor.

In A.D. 626 the fourth year after the Hegira, Mohammed, to promote the discipline and efficiency of its army, forbade the use of wine to the soldiers. This rule prevails in full force and effect in the Turkish army to the present day, with the result that the ottoman soldier's capacity for endurance and quick recovery from wounds is famous throughout Europe.

Of course, these views are quite in keeping with the experience of modern commanders, who have found that stimulants for soldiers are usually unnecessary and often harmful. Tea would seem to be the beverage most in favor with generals of the present day for troops on the march.

The Wounded During the Chinese Disturbances.

Dr. Oliver D. Norton, Surgeon, U. S. N., gives an account of the wounded American marines and soldiers who came under his care after the battle of Tientsin. Some of his observation were as follows:

Bullets of all calibers were used, but principally the Mannlicher; slugs from "two-men" guns; Mauser, '76 model; Winchester, .44 and .45 calibers, and Remington, .50 caliber. It was of interest to note that the high-power, small-caliber bullet shattered the bone; in no case was there a clean-bored or punched hole. The "hydro-dynamic" theory of high powered, small-arm bullets, or that the explosive effect varies directly at the viscosity of the body was found not to be true.

It was quite obvious that the deductions that have been made from experiments on cadavers, or cans of wet and dry sawdust, or sand, are not true when applied to the living body. The bullet acts differently and produces different results.

The laceration of tissue is noticeably absent in the small-caliber bullet wounds. There is a small punctured wound of entrance, and very slight, if any, pouting of the lips of the wound of exit. Wounds of the abdomen did well on rest, opium, and expectant treatment, but one case in five was lost.

Smokeless powder when blown into tissue at close quarters by the blast causesless pain and suppuration than black powder, and the grains are more easily removed.

Careful examination of wounds by the Mauser and Mannlicher at a range that varied from 2,000 yards to 400 yards failed to locate the so-called "explosive zone."

The foregoing observations are, in the main, similar to those made in Cuba, the Philippines, and South Africa. Dr. Norton's conclusions, with respect to the "hydro-dynamic" theory of high-powered, small arm bullets, is exceptionally interesting in view of the definite statements made on the matter by certain German observers.

The experience afforded in China, too, of treatment of wounds of the abdomen is quite in line with that of surgeons in South Africa and elsewhere.

Negro Density in the Far South.

Alarmists are much given to declaring that the negro population of the far South is increasing at a much more rapid rate than that of the white, and that there is always the fear that the blacks may one day swamp the whites in that part of this continent.

A writer in the *American Monthly Review of Reviews* shows that premises based upon such a belief are illusory, and that as a matter of fact the negro element in the far Southern States remains relatively stationary, while the white population is growing rapidly.

South Carolina and Mississippi are the only two States now in which the negroes outnumber the whites. In Louisiana the relative decrease of negroes has been very marked, but in Alabama and Florida the relative proportion of negroes has increased.

The black population appears to be concentrating in the low and warm regions of South Carolina, Georgia, Florida, Alabama, Mississippi, and Louisiana. Nevertheless, there has been a rapid increase of white population to colored in most States of the South.

Fibroma of the Integument the Cause of Pain Diagnosed as Articular Rheumatism.—Anna M. Lieser describes this case. The patient had been treated for articular rheumatism. The left knee was always painful, with occasional almost unbearable "spells" of pain. The sensation traveled up the thigh, posteriorly to near the hip, down the leg externally, to and into the foot. On examination, a tumor over the head of the fibula was discovered. It was removed under local anæsthesia. The tumor was oval in shape, involving the whole thickness of the epidermis and true skin, dipping into the superficial fascia. It measured 2 by 1⅜ by about ⅞ inches. It was a fibroma of the skin. The patient was entirely relieved of his pain after the removal of the growth. The pain had evidenty been caused by irritation of the external popliteal nerve.—*The Woman's Medical Journal*.

News of the Week.

The Illness of Dr. Paul F. Munde.—The many friends of Professor Mundé will be glad to learn that he is recovering from his late severe and dangerous illness and that there is a good prospect of his soon resuming his office work.

Epidemic Measles in New York.—A severe epidemic of measles prevails in this city, confined mostly to the upper east and west districts. Last year at this time scarlet fever showed itself in epidemic form.

Smallpox at Hackettstown, N. J.—Smallpox prevails epidemically in Hackettstown, N. J., and the town is quarantined. The health officers have taken possession of the new town hall as a hospital.

The Gift of a Tuberculosis Sanatorium in England.—It is announced that an anonymous philanthropist, who is, however, said by the *Daily Mail* to be Sir Ernest Cassel, has placed £200,000 ($1,000,000) at the disposal of King Edward for any charitable or utilitarian purposes which his Majesty may select. The money will be devoted to the erection of a sanatorium for tuberculosis patients in England. This institution will accommodate fifty male and fifty female patients. Twelve of the beds will be reserved for wealthy patients, who are able to pay for treatment, while the other eighty-eight will be for poor persons who will be expected to contribute a small amount. King Edward has appointed the following as an advisory committee: Sir William Henry Broadbent, Sir Richard Douglas Powell, Sir Hermann Weber, Sir Francis Henry Laking, and Dr. Charles Theodore Williams. Three prizes of £500, £200, and £100, respectively, have been offered in connection with this scheme for the best essays on and plans for the construction of the sanatorium, and the advisory committee will be guided by the result of this competition in the execution of his Majesty's wishes. The competition will be open to medical men of all nationalities. The institution will be located within easy distance of London, and every arrangement will be made for the convenient carrying out of the open-air treatment after the most modern methods.

Change in the Management of the Public Hospitals of New York.—The control of some of the city hospitals, namely, Bellevue, Gouverneur, Harlem, and Fordham hospitals, and the Emergency Hospital for Women, will pass from the Department of Charities on February 1 into the hands of a board of trustees appointed by the Mayor which, after that date, will have complete control of these hospitals. The board is to be known as the Board of Trustees of Bellevue and Allied Hospitals. It will consist of seven members, and the term of one of them will expire each year. When Mayor Low makes the first appointments, which under the Charter he must do by January 20, he will appoint one man for seven years, one for six, one for five, one for three, one for four, one for two, and one for one year. Thereafter the appointments are to be made for seven-year terms, except when it is necessary to fill vacancies, when the appointment is to be for the unexpired term of the retiring member. Before filling any vacancy, the Mayor must request the executive heads of the United Hebrew Charities of New York, the Particular Council of New York of the Society of St. Vincent de Paul, and the New York Society for Improving the Condition of the Poor to present a list of names of suitable appointees, but the Mayor is not obliged to appoint from the list submitted to him by the three societies named, and he can make his selections regardless of their recommendations, or he can call on any other organization or any citizen for suggestions, if he is inclined to do so. The members of the board are not subject to arbitrary removal but may be removed by the Mayor on account of any neglect, misconduct, or conduct that tends to discredit their office, or for mental or physical incapacity to perform its duties. This board will have power to appoint and at pleasure to remove, subject to the civil service laws and regulations, superintendents, medical officers and all such subordinate employees and officers as are necessary to the administration of the work of the hospitals. The Charter further provides that the medical Board of Bellevue and allied hospitals shall be composed of the attending and consulting physicians and surgeons on February 1, and vacancies in this board are to be filled by appointment by the Board of Trustees. The members of the medical board are to hold office as long as they satisfy the members of the Board of Trustees. The medical board shall nominate and the Board of Trustees, on its nomination, shall appoint medical and surgical house officers of the hospitals.

The State Hospitals.—In his annual message to the Legislature Governor Odell of New York expresses dissatisfaction with what he calls the duplication of administrative and executive powers, which, he says, is repugnant to sound business judgment. "First is the Board of Managers, with doubtful authority, then the Superintendent, who is the executive officer over all. The State Commission in Lunacy has not the authority to remove or even correct a superintendent, a treasurer, or a steward. The power, therefore, which they should have is lacking, and the Superintendent, protected by his Board of Managers, becomes an autocrat in the administration of his duties." But one result, he says, can follow such a system, namely, extravagantly managed institutions, with constant demands for improvements not warranted or justified. As a remedy for this condition, he recommends "that for the Boards of Managers there be substituted a visiting board for each district, to be appointed by the Governor annually, and to report to him, that the powers now vested in the present Boards of Managers be lodged in the State Commission of Lunacy, thus centralizing all authority in a commission that has been constitutionally created, which precedent has decreed must be non-partisan, and which is remunerated for the services performed."

Sanitary Condition of Cuba.—The report of Major W. C. Gorgas, Surgeon, U. S. Army, Chief Sanitary officer of Havana, for the month of November, shows a general sanitary improvement over the conditions existing in the same month of the previous year. The present death rate of Havana is 19.58 per thousand, a rate which compares very favorably with those for cities of the same size in the leading civilized countries of the world. Although the months of October and November have heretofore represented the period of maximum prevalence of yellow fever in Havana, and although for the past hundred years there previously had not been a day during these months when many cases of yellow fever did not exist in the city of Havana, during the present year this period has been passed without a death from yellow fever or the occurrence of a new case of this disease. From this fact Major Gorgas feels justified in making the claim that Havana has at last been completely freed from the infection of yellow fever. This result he believes to be wholly due to the systematic destruction of mosquitos in districts in which yellow fever developed. In the accomplishment of this result he states that there were 15,144 applications of petroleum made during the month, to the possible breeding places of these insects within the city. Those in charge of this work of mosquito destruction consider that during November of this year the number of mosquitos observed was only about one-tenth as large as during the same month of 1900. At certain places, for reasons not as yet understood, the number of mosquitos appears to remain about as large as during the previous year; but from many places in the city, where these insects were formerly very troublesome, they have almost entirely disappeared.

Health of the Army in the Philippines.—The health report of the Division of the Philippines for the month ending November 15, recently received by Surgeon-General Sternberg, shows 650 sick in quarters, 1,024 in regimental hospitals, and a total incapacitated of 2,952. The percentage of sick to the command was 6.79 per cent.

The Health of London.—The Registrar's report for 1901, recently issued, shows that the average death rate for the year in London, in a population of over four and a half millions, was 17.4 per 1,000. The aggregate deaths were 79,601, which is 9,874 fewer than the average for the last ten years. During the first half year there were 7,438 fewer deaths than usual. The highest death rate for any one week was 22.3 in November, and the lowest was 13.7 in June.

Hospital Saturday and Sunday Collection.—There was a large increase in the collections for the hospitals this year over the last or any previous one. The exact figures are not yet made up, but it is estimated that the amount collected will be in the neighborhood of $15,000. Last year the church collection amounted to about $12,000.

Dr. George B. Fowler of Brooklyn, who has served as Surgeon on the staff of Gen. James McLeer of the Second Brigade for several years, has been appointed Surgeon on the staff of Major-Gen. Charles F. Roe. His rank will now be Colonel instead of Lieutenant-Colonel. Col. Fowler was Chief Surgeon on the staff of Gen. Fitzhugh Lee during the Spanish-American War.

Opposition to Consumptives.—The town of Rockland, in Sullivan County, N. Y., has just adopted an ordinance imposing a fine of fifty dollars on any one who conducts a sanatorium, hotel, or other place in which consumptives are received, and imposing the same penalty on any one who receives into his house or harbors any consumptive not an immediate relative of the family or dependent upon him for support. A consumptive is not allowed even to visit relatives or friends in the town. In Liberty, a similar ordinance was passed a few weeks ago, and an epidemic of phthisiophobia appears to be sweeping through Sullivan County.

Arrest of an Illegal Practitioner.—A man named Ward, who is said to be a D.D., and therefore entitled to the appellation of doctor, who recently sued a woman in this city for $90 for treating her according to the principles of somatopathy, a system of treatment of which he declared himself to be the originator, was arrested last week on a warrant obtained by the counsel for the County Medical Society. Ward was charged with practising medicine without being legally qualified to do so. The man waived examination, and was held in $100 bail for trial in Special Sessions.

Osteopathy in New York.—A bill has been introduced into the New York State Legislature compelling the Board of Regents to grant a license to practise medicine to any osteopath who passes satisfactorily an examination in all the branches of medicine except materia medica and therapeutics. It is said that during the past year Speaker Nixon has been treated by one of these persons, and the osteopaths are counting upon his support of their measure. Last year a similar bill failed to pass

The Board of Health.—The Health Commissioner holds the record, thus far, among the members of the new city administration for changes in his department. At the first meeting of the new Health Board, composed of President Ernst J. Lederle, Police Commissioner Partridge, and Dr. Doty, Health Officer of the Port, out of a total of 1,009, 157 men were dropped from the payrolls of the department. The men dismissed include inspectors, vaccinators, disinfectors, and others occupying minor positions. They were dismissed, the Commissioner alleged, because they were unnecessary and because the department has no funds available for their salaries. A saving of about $110,000 was effected by the dismissals. The board confirmed Dr. Lederle's selection of the Medical Advisory Board, consisting of twelve physicians. No salary attaches to their office. · Those chosen are Drs. Edward G. Janeway, Joseph D. Bryant, T. Mitchell Pruden, William M. Polk, A. Jacobi, John Winters Brannan, Richard H. Derby, L. Emmet Holt, Alexander Smith, Francis P. Kinnicutt, and Henry P Loomis. Prof. Charles F. Chandler was chosen as consulting sanitarian and Dr. Hermann M. Biggs as medical adviser to the board. Dr. Joseph H. Raymond was appointed Sanitary Superintendent in Brooklyn in place of Dr. Robert Black, resigned. Dr. Raymond served in various capacities in the Health Department of Brooklyn for thirteen years, beginning as vaccinator and rising to be commissioner of health during Mr. Low's two terms as mayor there. Dr. Joseph A. Deghues was promoted from chemist's assistant to fill the place of chemist, made vacant by the elevation of Dr. Lederle. Dr. Edward F. Hurd was named as assistant sanitary superintendent for the borough of The Bronx in place of Dr. Eugene Monaghan, resigned.

The New York State Tuberculosis Hospital.—In his annual message to the Legislature Gov. Odell says that a site for the tuberculosis hospital has been selected and the work of construction will be begun in the spring. Concerning this he says: "Perhaps no work yet undertaken by the Sate presents so many serious aspects as does this. It has been estimated that there are 65,000 persons in the State of New York who are afflicted with tuberculosis. It is our duty, of course, to furnish every protection possible for the health and happiness of our citizens. This departure, however, may lead to the establishment of other institutions, for which the State may be called upon to provide and for which there may be the same claim advanced as by those who are stricken by this terrible scourge. A policy should therefore be defined. Hopeless cases should not be received, and every locality should be interested to the extent of preventing the admission of such incurables to the hospital. This can only be done when each locality is interested through the expense which it may incur in the treatment of these cases. The policy of the State, therefore, should be to provide accommodations and to assess upon each county the actual cost for maintaining each patient from such locality." He recommends that the supervising boards of counties or the common councils of cities should appoint examining physicians, without whose certificate no patient should be received into the hospital.

Reciprocity in Medical Licensure in Michigan.—In the synopsis of requirements for the practice of medicine in the several States and adjoining countries, published in the issue of December 21, it was stated that there was no provision for reciprocity in the Michigan laws. This was an error, and we are informed that in the Chander Medical Act, passed in 1899, there is a clause reading "The applicant shall be registered and given a certificate of registration if he shall present a certified copy [illegible] [illegible] which has been issued to [illegible] in another State of the Union, when the requirements for [illegible] shall be deemed by said board to be equivalent to those of this state, provided such State shall accord a like privilege to holders of certificates from this State. The fee for [illegible] of this sort shall be [illegible].

Meeting of the Ohio Board of Health.—The [illegible] annual meeting of the State and Local Boards of Health of Ohio will be held at Columbus Thursday and Friday, January [illegible] and 17, 1902.

An Army Surgeon Exonerated by Court-Martial, but Reprimanded by His Colonel.—A court martial recently held at Salt Lake City to try Major [illegible], post surgeon at Fort Douglas, charged with neglect of duty in failing to give proper treatment to soldiers under his charge, completely exonerated the accused. In spite of this verdict, however, Colonel Sumner, commanding the Department of the Colorado, administered a severe reprimand to Major Egan, asserting that the invalid soldiers in question did not receive the treatment they had a right to expect.

The Woman's College of Medicine in Chicago will, it is said, soon be closed and buildings and grounds sold. The difficulty is said to have been a lack of students, women wishing to study medicine preferring to do so in a co-educational school where their opportunities would be the same as those of male students.

College of Physicians of Philadelphia.—At the stated meeting held January 1, the following officers were elected for the ensuing year: *President*, Dr Horatio C. Wood; *Vice-President*, Dr. Arthur V. Meigs; *Secretary*, Dr Thomas R. Neilson; *Treasurer*, Dr. Richard H. Harbe; *Honorary Librarian*, Dr. Frederick P. Henry.

Professor Virchow Injured.—It is reported from Berlin that Professor Rudolph Virchow while alighting from a street-car on Sunday last, slipped and seriously injured his thigh. The cable dispatch does not state what the injury was, but says that it will not be dangerous in a younger man.

The Red Cross Society of Spain has made request to the War Department for information and photographic illustrations of the work of the Medical Department of the Army during the war with Spain, in the Philippines and in China. This society has undertaken the publication of a series of large volumes, elaborately illustrating the resources and operation of the medical departments of the various armies of the world, and it proposes to devote one volume to the humanitarian work performed in the armies of the United States and Spain during the late war. The photographs desired include representations of all arms of the service—cavalry, infantry, artillery, and hospital corps—on the march or in formation. Also photographs of field and base hospitals, hospital ships, ambulances and facilities for transportation of wounded, first-aid work by the hospital corps, etc. It is understood that the War Department is in possession of a considerable number of views of the above character, and will give every assistance to the Spanish authorities in this commendable work on this important subject.

Vital Statistics of Philadelphia.—The last week of the year shows a high mortality for the city of Philadelphia, 476 deaths having been reported for the week ended December 28 as compared with 432 for the preceding week and with 469 for the corresponding week of the previous year. Among the most conspicuous causes of death were: Pneumonia, 67; pulmonary tuberculosis, 56; heart disease, 39; nephritis, 22; diphtheria, [illegible]; smallpox, 19. There were reported during the week [illegible] cases of diphtheria, [illegible] cases of smallpox, 67 cases of scarlet fever, and 41 cases of typhoid fever.

Sanatorium for Tuberculous Patients at White Haven, Pa.—Plans have been completed for a number of cottages to be erected near White Haven, Pa., for the Free Hospital for Consumptives of Philadelphia. Work on two of the cottages is to be started as soon as the weather permits. One of these will afford accommodations for sixteen patients and the other for twenty-four. It is expected that there [illegible] [illegible] the work [illegible] continuing, as the present [illegible] to be housed in a tent [illegible] on the grounds which has been fitted up as a temporary sanatorium. The [illegible] thus far cared for have exhibited most gratifying improvement.

The Alumni Society of Gouverneur Hospital.—A meeting of the society was held on December 21 at the Academy of Medicine. The next regular meeting will be held on the first Tuesday in February.

Obituary Notes.—Dr. John Bull of Benton Harbor, Mich., died on December 29. He was a graduate of the New York University Medical College in the class of 1865, and had practised in Benton City since that time. He was prominent in the public life of Benton Harbor and served one term as Mayor of that city. He was a well-known Knight of Pythias and was the highest ranking member of that order in the world, having been elected Major-General of the uniform rank in 1898.

Dr. James Snyder Mackie died at his home in Newark, N. J., on December 30, of apoplexy. He was born in Cincinnati in 1824. He was a graduate of Union College, Schenectady, and was one of the charter members of the Psi Upsilon fraternity of that institution. He received a diploma from the Maryland College of Physicians and Surgeons, and for a time practised medicine in Baltimore, but later retired from practice and was for many years President of the Union Mining Company of Maryland.

Dr. John S. Stiger of Mendham, N. J., died on December 31. He was a graduate in arts of Princeton, and in medicine of the New York University Medical College, in 1849.

Dr. William H. Williams died at his home in Brooklyn on January 4, at the age of eighty years. He was a graduate of the Yale University Medical School in the class of 1847.

Dr. F. Edgar Downly, a prominent homœopathic physician of Clinton, Ill., died at the Hahnemann Hospital, Chicago, on January 5. He was a graduate of the Pulte Medical College, Cincinnati, in 1879, and at the time of his death was President of the Illinois Homœopathic Medical Association.

Dr. Elizabeth Darby committed suicide by shooting herself at Providence, R. I., on January 2. She left a note saying that despair had led her to the act.

Dr. Allanso Read, a dentist practising in Copenhagen for forty years, died on December 29. Dr. Read was a native of Pennsylvania, and occupied much the same position in Copenhagen as did the late Dr. Thomas W. Evans of Philadelphia in Paris. He numbered among his clients the royal family of Denmark, the royal family of Sweden, the Dowager Empress of Russia, Queen Alexandra, and many others members of various royal families, diplomats, and other notabilities. He declined to accept a title and other honors and retained his American citizenship.

Dr. George C. Devine died of pneumonia at Philadelphia on December 26 at the age of fifty-three years. He was graduated from Jefferson Medical College in 1872 and entered the United States Navy as an apothecary, serving in this capacity for four years. He had been a police surgeon for the last twelve years.

Correspondence.

FLOATING KIDNEY.

To the Editor of the Medical Record:

Sir: Last Thursday night, December 26, I took part in the discussion of Dr. A. H. Goelet's paper entitled, "Some Points in the Diagnostic Palpation of Prolapsed Kidney," at the section on Obstetrics and Gynecology of the New York Academy of Medicine. But owing to the time limit I did not say all I should have said. Therefore the remarks I have made may convey a wrong idea. I would therefore request you to publish in conjunction with the report of your stenographer the following: My remarks are based upon the experience of 661 cases which I have seen during the last ten months in my department of the Austro-Hungarian Hospital. Four hundred and ninety-eight cases were females, and 163 cases males. Of the females about 80 per cent. were palpated, of the males possibly only 40 or 50 per cent. My records show the following: Of the 498 females there were 137 cases of prolapse of the kidneys, or 27.51 per cent.; of the 163 cases of the males there were twelve cases of prolapsed kidney, or 7.36 per cent. Of the 498 cases in females there were seventy-six in which the right kidney only was prolapsed—15.26 per cent.; four cases in which the left kidney only was prolapsed and fifty-six cases in which both kidneys were prolapsed—11.24 per cent.; in one case only nephroptosis is entered without further defining. Of the 163 males (palpated possibly only 50 per cent.) there were two cases of ptosis of the right kidney only, two cases where the left kidney only was prolapsed; in seven cases both kidneys were in that condition, and in one case only nephroptosis is mentioned. My method of examination is: the patient lies on a couch, half way on the right side for palpation of the left kidney and half way on the left side for palpation of right kidney. In the examination I hold one hand in back and one in front—both hands being opposite one another. We feel for the kidney with the hand which is on the abdomen at the height of the short and deep inspiration, at the same time attempting to press with the hand behind the ribs and the structures in front of them forward, toward the palpating hand. In nephroptosis of the first and second degrees the palpating hand in front will feel the kidney flapping upward at the end of inspiration and our hand will distinctly feel the lower pole of the kidney. In nephroptosis of the third degree, where the entire kidney is felt coming down and both poles are palpable, the two hands feel the kidney; in quite a good many cases the hand on the back of the patient feels the kidney better than the one in front. As nephroptosis of the fourth degree, the usual floating, movable kidney is understood. Outside of this recumbent posture I occasionally palpate while the patient stands, or stands and leans forward. and, if I am not mistaken, I have also used the genupectoral posture. In suspected and difficult cases every known method should be used, so also Dr. Goelet's method. But I fail to see how Dr. Goelet's method could detect a nephroptosis of the first and second degrees, when only the lower pole—as in the first, and a larger part of the lower segment of the kidney, as in the second—is palpable. As to the symptoms attributed to nephroptosis by Dr. Goelet, I would say that all the cases that I have seen came to me consulting about their stomach troubles, which was no imagination, so that the presence of all the gastric symptoms enumerated by Dr. Goelet is correct. But to the question of whether a nephroptosis of the first, second and third degrees produces symptoms I will answer decidedly in the negative, unless the kidney itself is pathologically affected. Only the nephroptosis of the fourth degree, the floating kidney, gives symptoms which I have seen mistaken for uterine trouble, for neuralgia, for hysteria, for rheumatism, etc. The symptoms of the floating kidney can be summed up as those produced by pressure upon the circumlying structures and those produced by traction of the prolapsed kidney. As to the treatment. In my cases a well-fitting abdominal supporter has proved quite successful. An operation for the fixation of a prolapsed kidney might be good, but we are sure to try other methods first. In my cases I advise, besides the well-fitting abdominal supporter, a good corset, that is a corset with plenty of whalebone—not steels, which soon rust and break—which is to be worn right over a snug-fitting, thin undershirt (the snug fit is to prevent wrinkles). The object of the corset is not to produce the "fine figure," but to bear all the lacings of drawers, petticoats, and skirts. The corset must be so laced as to produce no pressure upon the stomach.

Mark I. Knapp, M.D.

136 East Seventy-eighth Street.

THE TECHNIQUE OF VACCINATION AND THE DANGER OF THE SHIELD.

To the Editor of the Medical Record:

Sir: Never have there been so many vaccinations in Boston and suburbs as during the last two months. Shields have been in almost universal use by the physicians, and very much irritation has been caused by them, in some cases septic infection. The simplest way of doing a given thing is the best, provided the result is the same.

For many years I have pursued the following course in vaccination and have yet to see a bad result, although some cases have "taken severely." I use the capillary tubes; drop the virus on the arm in the usual place; sterilize a needle in the flame of a Bunsen burner, and thoroughly scratch in the virus; let it dry for ten minutes, and then wipe dry with sterile cotton.

It is not necessary to wash the arm before vaccinating, unless the dirt is obvious, any more than it is necessary to wash the lobe of the ear before puncturing it for a blood examination. Neither is it best to scarify the arm before dropping on the virus. It saves both patient and physician to drop the virus first and scarify but once. If the arm is wiped dry with sterile cotton after vaccination, the blood serum dries at once, making nature's best shield. The patient is then instructed not to scratch or bathe over the vaccination.

I have seen a number of septic arms from the use of shields, especially where adhesive plaster was used. In one or two cases I have seen them all afloat with pus under the shield. The shield makes a bunch under the clothing, presses on the inflamed area, causing irritation.

As the shields are constructed, it is impossible to sterilize them, therefore they serve only as a source of infection and irritation.

If there is a discharge from the vesicle, I dust on aristol and compound stearate of zinc. In some cases of injury to the arm, where there is too much discharge for the powder to absorb, I cover the vesicle with a sterile sponge made of gauze. I think the shield a mere fad which will soon pass away. Charles A. Dennett, M.D.

Arlington, Mass.

RELATION OF THE DISPENSARY TO THE HOSPITAL.

To the Editor of the Medical Record:

Sir: The honest administration of charitable help for the sick poor is one of the most important of our acknowledged difficulties in the management of human affairs.

The abuse of free medical service by those able to pay for it being primarily a wrong against the medical profession, the remedy must come from the profession itself; that legislation is unable to cope with this question is shown by the daily farce encountered in the various clinics of the city, where abortive charity is administered, accompanied by the threat of fine and imprisonment.

Besides the large number of so-called walking dispensary patients who daily receive fraudulent treatment, there is the equally important, though not so frequently dwelt upon, class who, gaining entrance through the outdoor departments to the hospital wards, there obtain from the house and visiting staffs such medical or surgical treatment as their cases demand.

The medical man does not like the word advertise applied to his endeavors, but what else shall we call his efforts, by his writings, his published statistics, or his sectional medical society work, to bring his name before the world through the medium of his professional friends? I must therefore point out as a great first cause of unworthy occupants to hospital beds this selfish motive on the part of the visiting staff to secure material.

The medical man of ripe experience who secures the coveted appointment to the visiting staff of a hospital goes in with many ideas for the betterment of existing conditions. Weighing this matter too among the rest, he falls and will rather please his masters, the lay managing board of directors, by presenting reports of large numbers of patients handled than finish treatment. He thus leaves many behind with his expired term of yearly service.

What practitioner of medicine or of surgery has not lost pay patients through this maw of some hospital?

To determine where the patient came from, and who had the previous medical care of him, is of as much importance as are the diseases of his ancestry.

By acting only in conjunction with the previous medical attendant in some instances patients will be lost to the hospital, but I would show unto those who, having authority to order investigation of their ward-bed occupants, lack the stamina that in carrying them the life of the profession they deliver themselves, like Samson, to the fall of the house.

[illegible] Griffith, M.D.

[illegible] Monroe Avenue.

THE PAST WORK OF THE PATHOLOGICAL INSTITUTE.

To the Editor of the Medical Record.

SIR:—In your issue of November 30, 1901, Professor Hyslop of Columbia University entered a protest against the destruction of the work of the Pathological Institute by the present Commission in Lunacy. Dr. M. Allen Starr of this city has seen fit to make his reply to Professor Hyslop's letter in the daily press (the New York Times of December 9, 1901). In replying to Dr. Starr it seems proper to bring facts that must, where it belongs—before scientific men in general and the medical profession in particular.

From the positive statements and the assumed authority it is evident that Dr. Starr appears as the mouthpiece of the present Commission in Lunacy.

I think it just to give Dr. Starr an opportunity of stating the evidence whereon he bases his condemnation of the organization and scientific work of this institute.

I challenge him to substantiate and make good his statements that "the work done by the institute in the past three years had been wholly unsatisfactory to all those who are looking for some scientific effort at reaching the pathology of insanity." Also, that "no facilities were afforded in it [the institute] for the instruction of the assistant physicians in the asylums;" that "much money was wasted by securing a laboratory in one of the most expensive public buildings of the city, in Madison avenue, when far greater facilities could easily have been secured at no expense at the Wards Island Asylum," and that "the character of the work being prosecuted for the past two years" was "experiments in thought transference, in crystal gazing, in hypnotism, in clairvoyance, and in the study of occult phenomena of a certain psychological interest, but of no relation to the pathology of insanity."

Dr. Starr, as a man of recognized authority, and as spokesman for the present Lunacy Commission, is in duty bound to come out, without evasion or shifting of issues, and substantiate his specific statements, his arbitrary charges, against the work of the institute.

IRA VAN GIESON, M.D.

NEW YORK, January 4, 1902.

SANITARY REGULATIONS IN LIBERTY, N.Y.

To the Editor of the Medical Record.

SIR:—In your issue of December 28, you take editorial notice of certain reports circulated recently in the New York papers. These reports claim, in substance, that Liberty is waging a crusade against consumptives.

In the interest of truth, and in justice to our community, as well as out of consideration to the unfortunate health seeker, I wish to state briefly the facts in the case. In 1897 our Health Board passed a law prohibiting the maintenance of sanatoria in our village. Within the last four months an attempt was made to operate surreptitiously a sanatorium within the village limits. It was a sort of a branch to an out-of-town hospital. The Health Board promptly served notice on the manager that it must be closed. It was closed at once, no fine being imposed. This is absolutely all there has been to give color to the torrent of malicious and libelous reports so persistently circulated recently in the New York papers. These reports, following so closely on the heels of the closing of this insignificant concern, leave little doubt in the minds of our citizens as to the instigators of the libels. In the history of Liberty only four persons have ever been fined for expectorating. It is unnecessary, the law regarding it being generally observed.

So far from waging a crusade against consumptives, Liberty is offering every possible inducement to attract this class of people. As she has done in the past, so will she do in the future—welcome all health seekers with open arms and with every consideration of humanity.

J. L. C. WHITCOMB, M.D.

LIBERTY, N. Y., January 6, 1902.

Dr. L. E. Northfleet's Article.—By a ludicrous typographical error, Dr. Northfleet, in his interesting article in the issue of December 21, is made to say that he controls the fetal head by pressure behind the mother's arms, instead of *anus*. His real meaning was obvious, however, by the context.

Progress of Medical Science.

Boston Medical and Surgical Journal, January 2, 1902.

The Treatment of Placenta Prævia.—Frank A. Higgins believes it to be clearly demonstrated, from a study of the conditions, that under modern methods of treatment and reasonable aseptic precautions, the mortality from placenta prævia is not over 12 per cent in general, and under favorable circumstances, in skilful hands, it is below 5 per cent; that abdominal section is rarely ever indicated; that it does not even in favorable cases hold out promise of better than 10 per cent mortality; that its risks are much greater, and in unfavorable cases its mortality is prohibitive. In his opinion, the only cases of placenta prævia in which cæsarean section is ever justified, are those at full term, with central implantation of the placenta, with a rigid os, and when seen before the occurrence of any severe or dangerous hemorrhage, the mother and fetus being in good condition.

Rendering First Aid in Railroad Wrecks.—[illegible] Lofton proposes that every system of railroad should be equipped with a chief surgeon, and local surgeons distributed judiciously along the line most convenient to the road's hospitals. Every member of the train crews should be drilled quarterly, or oftener, if necessary, in the art of rendering first aid to the wounded. The control of hemorrhage should be the cardinal feature of the instruction. The location of the vessels, and the method by which they may be controlled in case of laceration, are features on which too much stress cannot be laid. The manner of bandaging, looking toward preventing infection and preservation of the parts which may be mangled, is of vital consideration always. The cry of the railroad surgeon is, "Death was due to shock." True, but hemorrhage from lack of appliances and immediate attention will cause this condition in 90 per cent of all cases. If bleeding be prevented, shock in this particular will practically become an obsolete term.

Traumatic Apnœa or Asphyxia.—H. L. Burrell reports the case of a man who had been caught between an electric car and a door post and held there for fully three minutes before the car was moved, when he fell unconscious. His chest had been compressed anteroposteriorly. When first seen, he was still unconscious, pulse [illegible], weak, but regular, respirations 30, shallow, with a groan at the beginning of each expiration. Several ribs were fractured. The most striking feature of the case was the condition of the man's skin. From the level of the third ribs upward over the neck and face and into the scalp, the skin presented a dusky, bluish, mottled appearance. In the eyes there was considerable conjunctival hemorrhage and minute retinal hemorrhages. This condition was at first thought to be cyanosis, but as the color was not all over the body, as it did not disappear on pressing the skin, and as it persisted, even after the patient's general condition improved, it was evident that cyanosis was not the cause. Treatment for shock was given, consisting of nitroglycerin [illegible] grain, atropin [illegible] grain, and strychnine [illegible] grain, subcutaneously, with ice cap to the head and heaters to the body. At the end of four hours' consciousness returned, after three days the patient was relatively comfortable. Eight days after the accident the blue color began to fade, and was practically gone three days later.

Journal of the American Medical Association, Jan. 4, 1902.

The Nature and Histopathology of the Epipharyngeal Tonsil.—N. H. Pierce presents the following conclusions: (1) The tissue composing adenoids has a wide distribution throughout the body. (2) The epipharyngeal tonsil is an organ normally present in all individuals. (3) Its function is at present unknown. It may be an evolutionary vestige or have to do with metabolic or other processes. (4) Its wide distribution in the animal kingdom, embryological connections, identity with lymphoid structures elsewhere, all suggest that it has a function. (5) Experiments suggest that it has an internal secretion. (6) The relation to it of tuberculosis, syphilis, and scrofula is not etiologic.

Living on Bread.—A. Haig gives several tables of uric-acid-free diet and calls attention to some common dietetic errors. He says: Eat when you are hungry and drink when you are thirsty, and if you go beyond this you are certain to suffer; but to introduce unnecessary uric acid and then try to wash it out with unnecessary water is to pile suffering upon suffering, even to the destruction of life itself.

He calls attention to the physiological necessity for diminishing meat and increasing relatively breadstuffs as one grows older. He notes that breadstuffs form a very convenient diet for those who are moving about the world, for they can be procured most anywhere and can be conveniently carried about. These cereals have been the foods of mankind in the past, and they are still the foods of the great majority, and only in parts of a few countries where flesh eating has been carried to great excess, have they fallen somewhat into the background. But here, as elsewhere, the majority are right, and the minority pay an enormous price for their unnatural but stimulating food. Among the flesh eaters, disease and death are rampant, the natural term of human life is but rarely attained, and even the shortened life is too often rendered both useless and miserable.

The Proper Management of the Tuberculous Lung.—Norman Bridge advises putting the lung at rest by general quiet and the introduction of nitrogen gas into the pleural cavity. Deep breathing is not always beneficial and advice thus to breathe should not be given recklessly. Everything should be done to encourage fibroid inclusion of the focus of disease. Chest gymnastics do tuberculous patients no good. Altitudes do not help by greater expansion of the air vesicles, but because they increase the number of red blood cells. Increase of pressure within the lungs by breathing through tubes of large inlet and small outlet is harmful. Public speaking should be interdicted in all lung cases. Cough should be minified so far as is consistent with free expectoration of accumulated phlegm, and cough should be made with as little pressure as possible. The crippled lung should be kept uppermost when the patient is recumbent. External fixation by means of adhesive plaster or similar device is most strongly to be commended. The movements of the diaphragm may be greatly limited by an abdominal binder. The author thus summarizes the advantages of immobilization: (1) Considerable relief from useless cough; (2) Increased ease in expectorating; (3) Relief from the annoyance of râles and wheezings, which tantalize some patients into desperate insomnia if not into the grave; (4) Relief of pain in the chest walls; (5) Relief from a sense of fatigue in the chest which so many patients have; (6) Lessening of fever, and consequently improvement in general nutrition and tone; (7) Lessening of danger of hemorrhage and assistance in recovery from its effects; (8) Aid in the healing of cavities, especially small ones; (9) Decrease in the amount of fibrosis beyond what is necessary for a conservative force.

New York Medical Journal, January 4, 1902.

Etiology and Treatment of Bright's Disease.—J. W. Brannan would summarize the treatment in the following directions: restrict protein food, prohibit strong alcoholic drinks, use dilutents freely, especially alkaline mineral waters, and promote the action of the skin and bowels. He regards the most frequent causes of acute Bright's as acute infectious disease and exposure to cold. Clinical histories of a case in a child and of one in an adult are given in detail.

Gelatinous Carcinoma of the Peritoneum, with Metastases in Sternum and Lung.—P. K. Brown and G. T. Brady report the case occurring in a man of sixty-four years. He complained of a slow growth in the size of the abdomen, with emaciation in other parts of the body. The case lasted over a period of seven years. Autopsy showed the mesentery to be occupied by a large deep-yellowish mass, which, under the microscope, revealed thick trabeculæ of dense fibrous tissue, containing but a moderate number of blood vessels, in whose immediate surroundings were to be found lymphocytes in variable numbers. Delimited by this stroma were alveoli of polygonal form, filled with finely granular, and in places thready, mucus. Only in the smallest was an epithelial lining demonstrable. Around the periphery in close rows was a distinct transparent membrane of long palisadal cylindrical cells, with a finely granular protoplasm. The nuclei were large, clear, oval, and situated in the lower third of these cells toward the basement membrane, while, toward the free edge, were seen all transitions of mucoid formation. Many of the cells were of typical goblet form.

Round Ligament Ventrosuspension of the Uterus; Improved Technique.—D. Tod Gilliam thus describes his operation: An abdominal incision three or four inches in length is made in the median line at the usual site between the umbilicus and pubes. The adhesions are broken up and the fundus brought forward. With a finger and thumb or a pair of bullet forceps the broad ligament of one side is seized and brought to the opening. By lifting up the anterior surface of the broad ligament on the tip of a finger applied to its posterior surface the round ligament is brought into view and is picked up, either between the thumb and finger, or with a bullet forceps. Selecting a point an inch and a half from the uterus, a thread is passed under the round ligament, and the ends of the thread are brought out of the opening and secured in the bite of a clamp forceps, which is laid upon the surface of the abdomen. The other ligament is sought for and secured in the same manner. At a point about one inch and a half above the pubes, the peritonæum, muscle, and fascia at one edge of the wound are caught up by a volsella and pinned together, being careful that the edges of these layers are in line. Traction is now made, and, with a small retractor, the skin and superficial fat are drawn in the opposite direction, uncovering the fascia. With a narrow-bladed knife, or better, with the perforating forceps devised for the purpose, a stab wound is made from the surface of the fascia into the peritoneal cavity, the instrument entering one half inch from the edge of the abdominal incision, and passing obliquely downward and outward, emerging on the peritonæum one inch from the edge of the abdominal incision. If the perforating forceps is used, the jaws are separated, and, by an outward movement of the handle, brought into plain view at the large opening. The thread which loops the round ligament is now placed in the jaws, the clamp forceps removed, and the perforating forceps withdrawn, bringing with it the thread and the ligament. If a knife has been used to make the perforation, it is withdrawn and a slender forceps introduced, with which the thread is caught up and the ligament drawn into place. Now, while the ligament is held taut, with its loop end a quarter or third of an inch above the surface of the fascia, a catgut suture is passed through it, including the tissues on either side, and back again, where it is tied. This is cut close to the knot, the suspending thread cut on one side close to the ligament and withdrawn, and the volsella and retractor removed. The other side is dealt with in like manner, and the abdominal incision closed.

Medical News, January 4, 1902.

The Requirements of Modern Surgery.—J. H. Carstens sums up the requirements of modern surgery as follows: (1) A patient brought to the highest stage of resistance to microbic infection and made as clean as possible; (2) An operating room, preferably in a hospital, where everything has been made thoroughly sterile; this includes anæsthetizers, assistants, and nurses; (3) A surgeon who has a mechanical hand, and has received a long and thorough training.

On the Absorption of Alexins by Tubercle Bacilli.—P. A. Levene states that if a given serum loses its alexin on treatment with a living germ, it is safe to say that the serum possesses a bactericidal power over the same germ. So, the presence or absence of alexins in a serum treated with living bacteria could serve as an indicator for the presence or absence in it of bactericidal power over the same bacteria. The writer states that in order to apply this method to the study of artificial immunity in tuberculosis the following questions present themselves for solution: (1) Whether normal sera lose their hæmolytic power on digestion with dead tubercle bacilli; (2) What the hæmolytic power of a given serum would be if treated with living bacilli; (3) If an animal should be found whose serum normally does not lose its hæmolytic power on treatment with living bacilli, would the serum of a tuberculous animal act differently? From his experiments, the writer has learned that there exists a certain "minimum" quantity of dead tubercle bacilli, which it is necessary to add to a given serum, in order to deprive it of its hæmolytic power. Living virulent bacilli added in quantities approximately equal to the "minimum" of the dead bacilli have scarcely any effect on the hæmolytic power of a serum; added in a larger quantity, they diminish this power, but in a lesser degree than do dead bacteria. "Attenuated" cultures act in the same way as the dead germs. When the serum of an animal previously treated with the extract of crushed tubercle bacilli is tested with living virulent bacteria, it loses its hæmolytic power far more readily than does a normal serum.

American Medicine, January 4, 1902.

The Fever of Hodgkin's Disease; Recurrent (Rückfall) Fever; Ebstein's Disease.—J. H. Musser concludes that: Hodgkin's disease is in all probability a lymphatic tuberculosis. Fever, recurrent in type, occurs commonly in this affection of the glandular structures. So-called recurrent fever is a symptom, not a disease. In a few rare instances the clinical diagnosis, when such fever prevailed, was malignant lymphoma (Pel), sarcoma (Völckers), myelosarcoma (Hammer), and lymphosarcoma (Remus and Witthower, Seebohn). Ehrlich and Lazarus believe that Hodgkin's disease is a lymphosarcoma, and that the tuberculous process is accidental. Sternberg, on the other hand, has pointed out the differences, and insists strongly upon the tuberculous as *the* process giving rise to the adenitis of Hodgkin's disease. He believes that the symptoms are different from those of other forms of tuberculosis, the anatomy of the gland having much to do with the process. The writer agrees with the conclusions of Sternberg.

A Case of So-called Malignant (Staphylococcus) Carbuncle of the Upper Lip Followed by Pyæmia.—Wm. B.

[illegible]

Nature and Treatment of Gout and Rheumatism.—B. L. [illegible] believes that both of these diseases are due to the same causes. They have their origin in damages of the body periphery and so are cutaneous disorders. The injurious factors are both telluric and atmospheric. The latter are both thermometric and barometric in nature. The best known are chilling, freezing, getting wet, exposure to draughts, to high altitudes, etc. The most injurious factor seems to be the combination of cold and wet. After the damage of the different tissues and organs of the skin, the injury frequently extends to the subjacent structures. Following this a toxic condition of the body fluids develops. This perverts the function of some or all of the most important organs. The author believes that the nature of the deposits in these diseases depends more upon the degree and nature of the destructive processes and upon the difference of the affected tissues than upon an excessive amount of uric acid in the body fluids. The treatment will have to be both preventive and curative. A dry and moderately warm climate is the best. The body surface should be exposed as often as possible. Sun baths and walking barefoot may be beneficial. The cases of general malaise so often seen, are due to the injury of a large area or the whole extent of the skin. The writer believes that acute and chronic kidney diseases are often due to local chilling. The best and most effective means to improve the vitality and function of the skin which admits improvement is the judicious use of cold water.

Philadelphia Medical Journal, January 4, 1902.

The Propagation of Yellow Fever by Mosquitos.—W. C. Gorgas reviews the sanitary work accomplished in Havana in the last few years and gives his reasons for believing that yellow fever is propagated by means of the mosquito. He believes that the result of the work done there in the last year is a very strong argument, at least so far as Havana is concerned, that the stegomyia mosquito is the only carrier of yellow fever, and that all cases there are transmitted in this way and in no other. In Havana, this fever never disappeared under any process before the American occupation, and for the past two years there has always been some yellow fever in Havana. As study of this subject went on the writer became more and more convinced that the mosquito theory was the correct one, and so last June the rigid quarantine of the patient was stopped, and the disinfection of fabrics and clothing ceased. It was only required that the patient be reported, his house placarded and screened, and a guard placed to report on general sick-room sanitation and to see that the patient was kept properly screened. By September the last focus was gotten rid of, and since September there has not been a single case. So in October and November, months in which before this time the disease was extremely prevalent, there has not been a death from this cause, nor even a case. The conditions have been as good this year as they ever were for the spread of the fever. And probably there have been more non-immunes in the city than ever before. The writer believes that it has been demonstrated that the disinfection of fabrics can be safely done away with, and many of the inconveniences of personal quarantine abated.

Rheumatic Fever and Its Counterfeits.—Sir Dyce Duckworth declares that all forms of arthritis or joint disease are the result of some infection, the only exception being gout. Arthritis which is independent of injury is always of an infective nature. He then speaks of various forms of arthritis. Post-influenzal arthritis is very clearly infective. Scarlatinal arthritis is generally of a pyæmic character and illustrates a disease due to a mixed infection. Gonorrheal arthritis is, of course, due to gonococcus. Dysentery is sometimes followed by arthritis. After cerebrospinal meningitis, arthritis which belongs to the pyæmic class may occur. In days gone by puerperal arthritis was seen. As a result of osteomyelitis or acute necrosis of bone, blood poisoning is produced by the distribution [illegible] fugitive character of the pains which pass from one joint to another quickly in rheumatism [illegible] greatly in making the distinction between rheumatism and pyæmia.

The Lancet, December [illegible]

A Case of Epidemic Diarrhœa in an Infant Treated by Irrigation of the Bowel.—W. B. Bennett reports the case, his patient being an infant of seven months. The usual purges, opiates, bismuth, etc., given by the mouth proving of no avail, the bowel was flushed with a solution of permanganate of potassium in hot water, about twelve ounces being used. The result was most beneficial, and the child made a good recovery.

A Case Illustrating the Effects of Pressure on Early Syphilitic Growths.—Basing his opinion on clinical observation, A. Shillitoe believes that (1) Pressure, as seen in the case of a phimosed prepuce, and (2) No pressure at all, as in the posterior third of the dorsum of the tongue, exert an equal influence in determining the formation of ordinary-looking papillomata, whereas, if the pressure be intermittent, as seen in the anterior two-thirds of the tongue, the inner aspect of the thighs, and the sides of the scrotum, or in the natal fold, then these papillary hypertrophies assume a condylomatous form.

Note on a Case of Purpura.—T. E. Sandall reports the case of a girl of fifteen years who complained of severe pains in the calf of the leg and popliteal space on both sides, but had no other symptom. The pain recurred at intervals, was considered rheumatic, and seemed to yield to the salicylates. Again it recurred, this time with greater severity, and was accompanied by a purpuric rash and a moderate fever, with some œdema of the legs and feet. Finally recovery ensued without any special treatment. The author confesses his ignorance as to the cause at the bottom of such attacks. There was no antecedent rheumatism in the history of the patient, and he is somewhat skeptical as to the value of the rheumatic theory of the causation of purpura.

Some Observations on Certain Trophic Hindrances to Bony Growth.—Heather Bigg has analyzed some [illegible] cases of infantile paralysis with reference to the point named in the title of the paper and divides them into three groups: (1) Cases in which the trophic hindrance continues during the whole period of bodily growth up to adult age, and in which the difference in length between the sound and the affected limbs continues progressively to increase during that period. (2) Cases in which the hindrance lasts only for a time, after which both the sound and affected limbs continue to grow at the same rate, and the then existing difference between the two remains stationary, and (3) Cases in which, after the hindrance has lasted for a time and then ceased, the affected limb tends to catch the sound one up in growth, and in some rare instances actually does so, so that the difference between them is either diminished or even extinguished. The first group represents a distinct minority of cases. The amount of loss in length varies and may be anything between three-quarters of an inch up to three inches, and even in rare cases more than this. The rate of hindrance to growth is generally even, that is to say, the heightening that has to be added to the shorter limb in order to keep the iliac crests level is superadded by regular increments during growth. Even with this trophic hindrance considerable motor recuperation may take place, and though from this it is clear that the trophic and motor changes bear no absolute relationship to each other, yet it is likewise a fact that the cases in which the original motor incapacity is the severest are generally those in which the trophic hindrance also becomes most marked, this probably being so because a more insuperable stretch of spinal cord has been (cicatricially?) involved. In the second group, if, for instance, a child is attacked at two years of age and the heightening necessary to keep the pelvis level is added by increments of an eighth of an inch (that being my usual fraction of measurement), these additions are at first rapid and regular, then less so, and finally, at perhaps the age of ten years, when the difference in the limbs may have reached from five-eighths to seven-eighths of an inch, no further addition is ever needed to be made. In brief, it would seem as if the trophic blocage in the spinal cord became gradually permeable and finally cleared. In the third group, the process seems somewhat analogous to those common examples in girls in whom one breast will develop some time before the other, and yet the latter when it starts will catch up with the other, and both will finally be of the same size. Bigg is inclined to attribute the improved results of later years to the fact that the affected parts are no longer kept in rigid apparatus, and while under such conditions easy walking became, by such means, immediately possible, all muscular movement was precluded, and, as a consequence, no motor stimulus was ever sent through or against the block in the spinal cord. But nowadays the rightful treatment is afforded by giving the paralyzed muscles only the exact amount of elastic assistance which they require, and in the effort of walking and balancing the trophic and motor blockages in the cord tend to clear. The consequence is that not only does the trophic hindrance frequently terminate, but in a large number of instances the motor power is gradually restored from the thigh downward.

British Medical Journal, December 21, 1901.

Angioneurotic Œdema of the Tongue.—Thos. F. Raven saw this case. The patient was a woman of eighty-six years in good health. The right half of the tongue was so œdematous that articulation and deglutition were difficult. No other symptoms were present, and no previous attack had occurred. She was a little weak and indisposed for a few days. Later, there was a more extensive attack.

Pneumococcus Arthritis with Notes of Seven Cases.—Nathan Raw concludes from his extensive observation of pneumonia that the pneumococcus is capable of producing very serious lesions in other parts of the body than the lungs. In 817 cases of pneumonia, arthritis occurred as a complication. This affection in all these cases occurred on the same side as the affected lung. The writer has observed in some cases of pneumonia a slight redness and pain in the shoulder-joint of the side affected, which has subsided with the crisis. The joint affection may either precede the lung symptoms, follow the crisis, or develop intercurrently. In Liverpool, alcohol seems to decide, in great measure, the severity and outcome of the attack. The writer believes in early evacuation of the pus, if it can be reached.

Case of Anthrax in Which the Infection Arose from a Hitherto Undescribed Source.—J. Connal Wilson reports this case of malignant pustule which occurred in a man aged twenty-six years. The patient had worked as a folder of leather in the manufacture of "pickers." A "picker" is that part of a weaving loom which receives into a hole made into its substance, the metal point of a shuttle at the end of its flight across the loom, and from this hole the shuttle is thrown back again to the other side. This "picker," then, must be very strong, tough, and yet resilient. It is, therefore, made of untanned hide. It is a common habit for the workmen to chew small bits of the hide. During the 160 years that this business has been established, there is not one other case of anthrax among the workmen on record. It has been said that "pickers" which are unfit for further use are sent to confectioners, who use them for making throat pastilles, jujubes, etc., for invalids.

On Rubella, Scarlatina, and "Fourth Disease."—P. Watson Williams declares that when it can be shown that an attack of "fourth disease" protects the patient from rubella and yet occurs in those who have previously had scarlatina, the evidence of its being a distinct exanthem will certainly be very convincing, but up to this time such evidence is lacking. The main points which, according to Dr. Dukes, serve to distinguish the "fourth disease" from scarlatina are its prolonged incubation, the usual absence of pre-eruptive vomiting, the low pulse rate, absence of desquamation of the tongue about the fourth day, absence of renal complications, and the shorter period of infectivity. The writer asks if it is not possible that some of the cases formerly recorded as "fourth disease" were not rubella and some scarlatina. He cites certain cases of a recent mild milk epidemic of scarlatina, calling attention to one in particular, that answered in all respects to the description of "fourth disease." Rubella occurs in two types, the morbilliform and the scarlatiniform. And it is a striking fact how one or the other type predominates in any one epidemic. But the same thing is true in regard to other infectious diseases. Scarlatina, also, appears in different types. The writer believes that evidence to prove the existence of "fourth disease" is still to be produced.

Berliner klinische Wochenschrift, December 16, 1901.

Morphology of the Typhoid and Colon Bacilli.—E. Saul brings forward studies which are somewhat new in character in regard to the morphology of these organisms. He considers the individual organisms as integral parts of one body or plant. According to this the organisms, when grown in colony formations under given conditions, produce characteristic colonies, or, as the author calls them, "plants." He therefore speaks of "typhoid plants" and "colon plants." He cultivates these "plants" upon agar and gelatine, and by means of formalin preserves them in limited growth for weeks and months. He produces several photographs to show that various bacteria, especially typhoid and colon bacilli, produce under these conditions "plants" which are characteristic of them. He believes that this method is of great service in differentiating organisms when the usual means are of no avail. Especially is this the case with organisms whose characteristics are closely related, such as typhoid and colon bacilli.

Splashing Sound, Atony, and Gastroptosis.—In discussing the relation of the splashing sound to gastroatony and ptosis, L. Kuttner says that it is essential to differentiate between the splashing sound and the so-called stomach murmurs. The first occurs when fluid and air are shaken together in the stomach. Stomach murmurs, on the other hand, are most often heard when very little or no fluid, but a considerable amount of gas, is present, and the patient by muscular power or the examiner by pressure of the hand depresses the epigastrium. Splashing sounds are most easily produced in the horizontal position, and although stomach murmurs may also be produced by the examiner when the patient is lying down, yet in this position the patient himself by muscular effort cannot produce them, but can only do so in the upright posture. Furthermore, in true splashing sounds, when deep epigastric pressure is made with the finger, the presence of fluid in the stomach is appreciated. Stomach murmurs are of no diagnostic importance. The pathological significance of splashing sounds depends upon the length of time that they are elicited after fluid has been received into the stomach. If they are present only shortly after the reception of fluid they possess no diagnostic value. They are of great value, however, when elicited hours after fluid has been taken. Under these conditions a splashing sound produced by superficial pressure is a pathological phenomenon. The appearance of this sound is dependent upon the tone of the stomach muscle and the condition of the abdominal wall. For the production of the sound the position of the stomach is only of secondary importance. The presence of the sound means atonia ventriculi, if it is produced during the time of gastric digestion. If it persists for a longer time than this, motor insufficiency is present. The amount of fluid which remains in the stomach can only be ascertained by the evacuation of the same. If a true splashing sound is present during fasting, it is necessary to wash out the stomach, in order to determine whether parasecretion or motor insufficiency is the cause. Atony of the stomach signifies a laxity in its muscular structure. The same is often dependent upon constitutional causes, and is often only a single expression of an "asthænia universalis congenita." Atony and motor insufficiency are not to be considered as identical. In simple atony the motor function for the usual test meals may be normal, but generally the motility of the organ is slightly reduced. High-grade motor insufficiency in simple atrophy is of short duration. Gastroptosis is often a sequel of atony. Here the functions of the organ may be normal, but this is not usually the case. In gastroptosis the location of the greater curvature cannot be determined by localizing the splashing sound, but can only be ascertained by deep palpation.

Hæmolysis in Heterogeneous Serum.—P. Baumgarten reiterates his assertion that the hæmolytic action of serum is a diffusion process due to osmotic currents. A similar process takes place when red blood cells are introduced into certain anisotonic salt solutions. That this is not, however, the only factor in the hæmolytic action of serum is shown by the fact that hæmolysis is much more active and rapid in serum than it is in such salt solution. Certain substances, must, therefore, be present in the serum, which favor the osmosis. By analogy we know that such is possible, for the addition of traces of acids to anisotonic solutions increases their osmotic power. These substances, which correspond to the "immune bodies" of Ehrlich, are identical with the agglutinins. Ehrlich denies this because in his experiments the serum of goats that had been inoculated with the blood of sheep dissolved the red blood cells of the latter without producing any agglutination what-

[illegible] This agglutination, however, [illegible] are apparently [illegible] that in these organisms the hæmolytic power of the blood is so strong that it completely overshadows the agglutinating power. This may be easily demonstrated by diluting the active [illegible] serum to which the red blood cells are to be added. By diluting from five to ten times, it is seen that in every case agglutination precedes the hæmolysis. That the immune body or agglutinin cannot alone produce hæmolysis is proved by the fact that serum heated to 55° C. retains its agglutinating power, but loses its hæmolytic action. That hæmolysis is due to a physical rather than to a digestive process may be amply proven by experimentation. The digestive action of trypsin solutions upon red blood cells is a slow process. Five or six hours are required before any appreciable result is obtained. On the other hand, hæmolysis in heterogeneous serum is completed at the latest in two hours. Serum is a fluid that contains substances which produce osmosis, and it is entirely conceivable that the sera of various animals contain different amounts of these substances, and also that the osmotic pressure in the red blood cells of such animals is not the same. The fact that one half hour heating of the serum destroys its hæmolytic power but not its agglutinating power shows that osmosis is the principal factor in hæmolysis, because it is a well known fact that the heating of osmotic fluids destroys their activity. Sera or other osmotic fluids made inactive in this manner may have their activity restored by adding to them various quantities of osmotic fluids, and in direct proportion as such added amounts are small or large. The addition of hyperisotonic salt solution to serum thus made inactive is able to restore its hæmolytic power, and it is not at all necessary that neutral serum be added. All of these facts, together with the direct microscopical observation of the hæmolytic process in heterogeneous serum, lead to the conclusion that this process is essentially osmotic in character, although the osmosis is undoubtedly facilitated by the presence of certain substances in the serum.

Münchener medicinische Wochenschrift, December 17, 1901.

The Plastic Surgery of Tendons.—A. Hoffa says that plastic tendon operations are not only of avail in the rectification of certain paralytic deformities, but are followed by good results in numerous spastic contractures and traumatic tendon malformations. In order to ascertain the best mode of procedure, he has undertaken experimental work upon dogs and cats. These animals were killed at various times after operation, and by examination the results ascertained. He employed various procedures which involved the shortening and lengthening of tendons and the transplantations of their insertions. As most suitable for operation he selected the tendo Achillis and the tendons of the paw. In the regeneration which takes place the tendon tissue proper, the peritoneum internum and externum, and the peritendinous connective tissue are all concerned. During the first few weeks the newly formed tissue is principally of the connective type, but gradually this is very largely replaced by tendon tissue proper. If sepsis intervenes, connective tissue predominates. Extensive hemorrhage at the time or subsequent to the operation markedly retards the healing process and materially reduces the chances for satisfactory results.

Disinfection of Tuberculous Apartments.—D. Ottolenghi contradicts the assertion of F. Steinitz that the disinfection of tuberculous apartments with formaldehyde and a 2-per-cent. sublimate solution is efficient for the destruction of the bacilli. His experiments show that a 2-per-cent. solution of bichloride to which various proportions of hydrochloric acid or sodium chloride have been added is necessary to produce anything like satisfactory results. Indeed, Steinitz's own experiments show that the method recommended by him is inadequate. Steinitz has objected to the general rules for the disinfection of tuberculous apartments, laid down by Ottolenghi, because the experiments leading to their recommendation were conducted by the employment of paper contaminated with sputum, because twenty-four hours' contact is necessary for complete bactericidal action, and because the saturation of walls, furniture, etc., with a bichloride solution is impractical. Investigations in which carpets, furniture, walls, etc., have been thoroughly saturated with the bichloride solution recommended have amply demonstrated that an efficient bactericidal action is obtained thereby. The fact that twenty-four hour's contact is necessary is no valid objection, for in cases of necessity the apartments may be immediately occupied after the disinfection. The statement that this method is impractical of application is not borne out by facts. In several cities, notably Turin, it has been in routine use for many years. The author has personally made no comparisons between the value of formaldehyde and that of sublimate disinfection, but the work of others, even of Steinitz himself, shows that the former is inefficient when thick layers of dried sputum are present. Many, however, have demonstrated that 2 per cent. bichloride solutions give satisfactory results under all conditions.

A New Symptom for the Diagnosis of Cancer.—Leser says that the presence of certain small cutaneous tumors is an important aid in the diagnosis of malignant growths, particularly carcinoma. He describes these tumors as follows: The changes in the skin consist in the appearance of exceedingly small, bright or bluish red spots, which are raised above the surface of the skin and can be readily appreciated by lightly passing the hand over the cutaneous surface. They are sharply differentiated from the surrounding normal skin. As a rule they are present only upon the trunk. Exceptionally, however, the limbs may be affected. They are never found upon the hands or feet. Very often their location bears no relation to the course of the blood vessels or nerves. As a rule they are principally observed over the region where the carcinoma is located. Macroscopical and microscopical examination shows that these tumors are to be considered as angiomas. Whether a direct connection exists between them and the malignant growth has not as yet been decided. In fifty cases of carcinoma observed by Leser, these cutaneous tumors were present in all but one. Their number varies greatly, but they are usually extremely numerous. From fifty-eight to seventy-six have been observed in single cases. Generally they are more numerous in men than in women. He has examined 300 persons, in order to ascertain their diagnostic value. Many of these persons were affected with carcinoma, and many were, so far as could be ascertained, absolutely sound. It is without doubt true that many healthy individuals, after they pass fifty years of age, show cutaneous tumors similar to those which have been described, but they are much less numerous than those which are associated with carcinoma. It may be stated without hesitation that their presence in large numbers in persons under fifty years of age is highly significant of carcinoma, and is a valuable diagnostic sign. Further observations along this line are greatly to be desired, especially as to whether these tumors are present before the first symptoms of malignant growth appear, and are directly related in etiology to it. Or, on the other hand, are they merely accompaniments or sequelæ of carcinoma? Furthermore, is their disappearance of prognostic value in cases of operative interference?

Deutsche medicinische Wochenschrift, December 19, 1901.

Experimental Glycosuria.—Pavy says that the presence of sugar in the urine can be accounted for in four ways: (1) The non-assimilation by the body of the carbohydrates introduced therein. The body disposes of the carbohydrates introduced by changing them to fat, proteids, and glycogen. Whenever these processes are not intact, or the amount of carbohydrates introduced is too great to be thus disposed of, sugar becomes present in an excessive amount in the blood, and consequently appears in the urine. (2) The abnormal conversion of glycogen into sugar. Here the carbohydrates which have already been assimilated as glycogen are broken down in an abnormal manner. The carbohydrate molecules of the glycogen are separated from the nitrogen molecules without affecting the latter. (3) From the breaking down of proteids and the consequent liberation of sugar. In this form of the destruction of proteids the carbohydrate molecules and nitrogen molecules are equally affected, so that this glycosuria is constantly accompanied by an increase in the nitrogen compounds in the urine. (4) Glycosuria due to the metamorphosis of fat. Such a breaking down of fat takes place in plants, and by analogy it is to be supposed that the same can occur in the animal body.

Gonococci in the Blood in Gonorrhœal Polyarthritis.—Ernst Unger reports a case of gonorrhœal polyarthritis in which a coccus, responding to all the tests for the gonococcus, was obtained in pure culture from the blood taken from the median vein. These organisms were also present in the urethral discharge. The arthritis was at first limited to the left hip-joint and responded well to treatment; when it began to decline, however, the wrist and ankle-joints became affected. The primary attack was apparently due to traumatism. On account of this, and also because the urethral discharge was slight and at first overlooked, it was originally thought that the patient was suffering from an osteomyelitis, especially as the tissues of the thigh were much swollen and very tender. The subsequent detection of the urethral discharge with gonococci therein, together with the presence of these organisms in the blood, settled the diagnosis. In all endeavors to obtain gonococci from the blood three rules should be followed: (1) The withdrawal from the patient of at least 10 c.c. of blood. (2) Marked dilution of the blood in order that its bactericidal properties may be nullified, and the organisms not killed before they are transplanted into artificial culture media; (3) The selection of a suitable *fluid* culture media for the cultivation of these organisms. This is an important point as organisms obtained from the blood grow much more rapidly upon *fluid* than upon *solid* media. When only a few organisms are present in the blood, the chances of obtaining a satisfactory growth are much increased in this manner.

French Journals.

Encephaloid Endothelioma of the Transverse Mesocolon; Ablation.—Albertin showed a very large tumor which was taken from a patient fifty-eight years old. In spite of the uncertain diagnosis, the progressive gravity of the condition of the patient demanded intervention. After the abdomen was opened the tumor appeared. Before it was punctured, it seemed to fluctuate, but after it was opened there was no liquid to be seen in it. The mass was rapidly enucleated by means of cleavage. The interest of this case consisted in the febrile phenomena during the rapid evolution of the tumor, the difficulty of diagnosis, and finally the facility of enucleation. The patient soon died of progressive cachexia. Histological examination showed the growth to be an endothelioma of the peritoneum of malignant nature.—*Lyon Médical*, December 22, 1901.

Infectious Endocarditis and Embolic Aneurysm of the Abdominal Aorta.—Huchard and Bergouignan report their observation of a man twenty-six years old, who for seventeen months had been subject to attacks of fever of malarial type. It was only during his sojourn at the hospital that endocarditis appeared, of which the first manifestation was an embolism of the left popliteal. A systolic murmur was not detected till a few days later. Embolism of the left brachial, infarct of the kidney and of the spleen followed. On autopsy there was discovered a serious vegetative ulceration of the mitral valve, and multiple infarcts of the right kidney and the spleen. But the most interesting lesion was an aneurysmal pouch of recent formation, at the level of the bifurcation of the aorta, adherent to the vertebral column, and prolonged toward the left common iliac, in the form of a dissecting aneurysm. The left common iliac was considerably contracted. This lesion of rapid evolution followed the endocarditis; it came from an infectious embolism, which caused a limited destruction of the internal and middle coats of the aorta.—*Gazette des Hôpitaux*, December 24, 1901.

Tuberculous Lymphadenoma.—Duret concludes that there exists a form of ganglionic hypertrophy, polyadenopathy, especially frequent in the cervical region, which simulates true ganglionic neoplasms, principally lymphadenoma and lymphosarcoma. Microscopical examination and especially inoculation of animals demonstrate the tuberculous nature of this hypertrophy. These tuberculous ganglionic hypertrophies are relatively of slow growth in comparison with the true neoplasms. As a general rule they do not end in suppuration. They are progressive in their development. Now and then, during the course of the disease, there are periods of especially rapid growth which are often accompanied by elevation of temperature. When these hypertrophies are the seat of a secondary infection, the course is rapid. In some cases they are susceptible to retrogression, but they often open the way for the development of visceral tuberculosis. General treatment has only an uncertain action. The extent and multiplicity of the lesions scarcely permits local, medicinal treatment. Extirpation offers the best course. In most cases cure has resulted. It is probable that the majority of tumors called lymphadenomata have a tuberculous origin.—*Journal des Sciences Médicales de Lille*, December 21, 1901.

Tuberculous Infection of the Female Genital Organs.—Simon Duplay and S. Clado classify these cases as accessible and utero-adnexial. The treatment of the first class consists in antiseptic irrigations, cauterizations—either chemical, or by the thermo-cautery—excision by bistoury, or curettage, or in all these measures combined. In tuberculosis of the uterus and adnexa, with ascites, after evacuation of the liquid by laparotomy, a part of the whole of the body of the uterus, together with the adnexa, is extirpated. The extent of the extirpation will depend upon the extent of the lesions. If the disease has extended considerably into the peritoneal cavity, so that cysts have formed in the region of the umbilicus, the purulent cavities should be cleaned out after an incision has been made. The manipulations should be made with the greatest care, on account of the danger of a fecal fistula, the intestine being so friable. The prognosis is always grave. When fistulæ exist—vesico-intestinal, intestino-cutaneous, or intestino-vaginal—it is most difficult to decide upon the course to pursue. Few of these cases profit from surgical intervention, but on the other hand, all succumb to the cachexia when there is no intervention. Especially must the general condition be looked after. The writers conclude by insisting upon the importance of general treatment, which should be begun without delay.—*Archives Générales de Médecine*, December, 1901.

Book Reviews.

Anatomy in Its Relation to Art. By George McClellan, M.D., Professor of Anatomy at University of Fine Arts. 4to, 133 pp. W. B. Saunders & Co., Philadelphia and London, 1901.

The artist of the human figure, be he sculptor or painter, who has no knowledge of his anatomy, is ever guessing at results, but never sure of his ground. Nor will he ever be, until he has mastered those necessary rudiments of bodily construction which lie at the bottom of all true and intelligible delineations of form, posture, and action, whether in speaking bronze or on glowing canvas. It is the reason why, which is the basis of his necessary knowledge of the construction and pose of the human form in all its various phases of physical expression. As the author truly says, "Anatomy for art purposes should never be obtrusive, but it should be sufficiently inclusive to encompass all the necessary analyses of form and position which appeal to the artistic sense. In other words, the superficial, artistic anatomy should give every possible interpretation of motion, form, posture, and proportion necessary for accuracy of execution, as well as beauty of finish and perfection of outline. Professor McClellan has done his best to such ends, and in many respects his work along different lines is quite unique. Especially is this so with the numerous schematic representations of muscular projections under the different conditions of tension and posture of body and limbs. The male and the female figures which represent the studies of the author are not strictly classical, and would hardly be accepted as models; but they represent proportion, and this is probably enough for mere scientific study. The facial expressions are excellent, although the particular muscles which govern them are not made clear, or are not specially differentiated. The author is at his best in demonstrating the various actions of the limb muscles, although in some of the figures there is a trifle more of detail in skeletonizing his sketches than would seem to be warranted. In one or two instances in which the legs are crossed in a sitting posture, the deeper tracings of bone and muscles are somewhat confusing. The descriptive text has been carefully adapted to the wants of the lay reader, and is conspicuously devoid of technical terms. In fact, this portion of the work is beyond criticism, and cannot fail to meet the varied needs of the earnest art student. It is unnecessary to refer to the many illustrations which are scattered throughout the work. All are excellent of their kind, but particularly is this the case with the full-page plates presenting the nude figure in all the varied positions for studio work.

A Reference Handbook of the Medical Sciences, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A new edition, completely revised and rewritten. Edited by Albert H. Buck, M.D., New York City. Vol. III. Illustrated by chromolithographs and 676 half-tone and wood engravings. New York: William Wood and Company, 1901.

One hundred and forty contributors have furnished the articles in this volume, carrying the work along from "Chloralamid" to "Equinox Spring." Among the more important subjects treated of are: chloroform, chorion, circulation of the blood, cranial nerves, deaf mutes, dermatitis, dietetics of the sick, diphtheria, dislocations, dysentery, the ear and its diseases, eczema, electricity in all its medical applications and relations, and epilepsy. These are only a few of the most prominent articles noticed in glancing through the volume, but almost every imaginable subject falling alphabetically between the limits above noted can be found in the 860 pages of this book. They vary, of course, in interest and in manner of treatment; but in scarcely one of these, to which we have turned in order to test the value of the book as a work of reference, have we failed to find just the sort of information desired, conveyed for the most part in clear, concise language, aided, where necessary, by helpful illustrations.

Circumstance. By S. Weir Mitchell, M.D., LL.D., Harvard and Edinburgh. New York: The Century Company, 1901.

In this story of an adventuress who has wormed her way into the confidence of the head of an old Philadelphia family, Dr. Mitchell has given us one of the best of his happily lengthening list of novels. The tale has to do with the varying fortunes of this adventuress during a comparatively brief portion of her career and also with those of an eminently respectable and pedigreed family forced for a time into partial subjection to this woman. The story is well told, and the character painting is strong. The meaning of the title is [illegible] "Circumstance." None of the actors seems to have been influenced or forced [illegible] character by circumstances more than most persons are. The adventuress, of course, recalls the immortal creation of Thackeray, although there is really no comparison possible between the two. Dr. Mitchell is not an imitator, and he remembers the character of Becky Sharp's [illegible] only in [illegible] of woman [illegible] good and [illegible] Both Dr. Mitchell and his readers are to be congratulated upon the fact that with each new book his characters are allowed to explain themselves [illegible] talk [illegible]

The Diagnosis of Nervous and Mental Diseases. By Dr. Howell T. Pershing, Professor of Nervous and Mental Diseases in the University of Denver. 221 pages. Philadelphia: P. Blakiston's Son & Co.

The author says that the object of this little book is to facilitate the recognition of nervous and mental diseases by physicians who are not specialists in neurology. The larger portion of the book is taken up with diagnostic tables based upon the principle of botanical tables, i.e., with a "key." The author has probably found them useful for his students and for himself, otherwise he would not have published the volume, as there is no dearth of manuals devoted to the principles of diagnosis and the mode of examination, with which the first part of the volume is concerned. It remains to be seen whether they will be useful to the general practitioner. Despite our desire not to prejudice him, we are of the opinion that such tables are of little or no service to him, it matters not how thoroughly they have been prepared. Nor do we see clearly how such tables will make the fuller knowledge of the best textbooks more readily accessible to the busy physician. That knowledge is just as accessible as it will ever be to him who does not seek it, and it is entirely intelligible to him who knows, or who wishes earnestly to acquire, the first principles of diagnosis.

The section entitled the "Signs of Hysteria" does not do the author credit. Hysteria may be "a diseased condition in which perverted ideas and emotions cause the bodily symptoms," but to say so is pure assumption on the part of the author. It may or it may not be so. Any enumeration of the stigmata of hysteria that does not lay stress upon the abulias, the amnesias, the fixed ideas, the deliria, the modification of character, to mention no others, is very incomplete. The book is written in plain, concise language, and the practitioner who is not read in neurology may peruse it easily; but as we have intimated above, the author's students will probably find it more useful than any others.

Memoirs and Letters of Sir James Paget. Edited by Stephen Paget. London, New York and Bombay: Longmans, Green & Co., 1901. 8vo., pp. 427.

This biography of a great man is in itself a great book. The story of his early life is partly told by the subject himself in his modest, terse, and interesting way, and the after-history by his son.

Much space is judiciously occupied by correspondence covering different periods, and forming a proper connecting link of narrative with the main portions of the work. As each life, when its history is properly told, carries with it a lesson, this one is especially so in the varied incidents which depict the well-rounded character of a man who was ultimately a success after the most patient and painstaking endeavors. It is the old story of hard work and the ultimate reward in the end.

The picture is an interesting one as presented in the artistic finish of detail and correctness of outline. As a biography it is a model of its kind in satisfying the reader with every estimate of the real character and purposes of the subject of the sketch.

In every part there are touches of nature skilfully presented which give just enough of family life to make one acquainted with the individual peculiarities and personal traits of the man we wish to know. In other words, we almost see him now and hear him tell of his early struggles, his deferred hopes, his patient waiting for results, and his final triumph, and the actual realization of his wildest dreams of fame, influence and power. The study of such lives is an inspiration which can only be appreciated when such a book is in hand, and the reader follows step by step the gradual advance to greatness.

There is much of the early history of St. Bartholomew's Hospital which was so intimately associated with Paget's work, and also of many of his contemporaries. Incidentally also many interesting facts in the same connection bear upon the development of medical teaching, particularly at the direction of pathological research, all of which are interesting and suggestive in view of the advanced methods of the present. But these are of a general import, which, however, have their real interest in the personality of the individual about whom the whole story revolves.

The Medical News Visiting List for 1902. Philadelphia and New York: Lea Brothers & Co. 1902.

This is the first of the physicians' diaries to come to our table. It is for thirty patients per week—ample for the use of most of us. Its arrangement is practically the same in all of the visiting lists, and this, like the others, contains a number of useful memoranda on the treatment of emergencies, a dose table, therapeutic reminders, etc. A very useful bit of advice with which the book opens is: "Keep your visiting list in such a way that you can fully explain it."

The Medical Record Visiting List or Physicians' Diary for 1902. New York: William Wood & Co.

This visiting list, so long and favorably known to the profession, has been newly revised. The most important changes are in the list of remedies and their maximum doses in both apothecaries' and decimal systems, and the indication of such as are officinal in the United States. It is arranged for thirty or sixty patients weekly, is handsomely bound, and of convenient pocket size.

On Paralysis Agitans, With an Account of the Clinical Features of Other Forms of Tremor. With ten Illustrations. By R. T. Williamson, M.D., London, F.R.C.P. Manchester: Sherratt & Hughes, 1901.

R. T. Williamson, whose previous work on "The Relation of the Diseases of the Spinal Cord to the Distribution and Lesions of the Spinal Blood Vessels" has left a favorable impression, gives in this book of sixty-eight pages a summary of what is known regarding Parkinson's disease, and adds thereto a short discussion of the various kinds of tremor. The clinical description of paralysis agitans is clear and wholly adequate. The author prefers to speak of "fixation" rather than rigidity, "in order to distinguish this condition from true spastic paralysis." The point, though a small one, is well taken, but really there is not much danger of confounding paralysis agitans with spastic hemiplegia or paraplegia. The writer includes an account of Moczutkowsky's sign. If there ever was reason to protest against names in clinical nomenclature, it applies in this instance. There is danger that any one attempting to remember the name would exhibit the symptom—namely, "the patient is told to wrinkle the forehead, and to keep it wrinkled for one or two minutes. The folds persist for forty or sixty seconds after the patient has ceased the muscular contraction." Let us call it "protracted wrinkling of the forehead," and be done with it.

The section on diagnosis is altogether too brief. It is astonishing that an author who is capable of good histological work should not have awaited the opportunity for a post-mortem examination before publishing this summary. As it is, the section on pathological anatomy and pathogenesis merely enumerates the various conflicting theories, and the author is not able to throw additional light on the anatomical basis of the disease, though he seems inclined to favor the theory of its purely cerebral origin.

In the matter of treatment he recommends hyoscine and duboisine. He seems to us to be unduly alarmed regarding the effects of the former drug, for the present reviewer, in common with others, has noticed the relative inertness of the hydrobromate of hyoscine unless given by hypodermatic injection.

The concluding pages on the various forms of tremor constitute a valuable contribution to the differential diagnosis of tremor, and the entire booklet will be found useful by every one who is specially interested in shaking palsy and allied diseases.

The Accessory Sinuses of the Nose, Their Surgical Anatomy and Their Diagnosis and Treatment of Their Inflammatory Affections. By A. Logan Turner, M.D., etc., Surgeon for Diseases of the Ear and Throat, Deaconess Hospital, Edinburgh. With forty plates and eighty-one figures. 8vo, 211 pp. Edinburgh: William Green & Sons, 1901.

This volume is built up on a series of lectures given by the author before the College at Edinburgh, and on an essay on the "Racial Characteristics of the Frontal Sinuses." The various sinuses are first described from the anatomical point of view. Then follow chapters on the openings of communication between the accessory sinuses and the nasal chambers, the comparative anatomy of the frontal sinuses, transillumination, etiology and pathology of suppuration in the accessory sinuses, diagnosis, and treatment. The chapter on comparative anatomy is most interesting, and has already become authoritative in this field of literature. In the other chapters only familiar ground is traversed, and not much said that is essentially new. Yet the presentation of familiar topics by careful clinicians always advances the sum total of our knowledge. From this standpoint the work of Turner is to be highly commended. The illustrations are unusually clear and the whole setting of the book most attractive. Concerning the much-discussed question of the relation of ozæna to sinus disease, the author states that the relation of cause and effect is still debated. Where sinus disease is associated with polyps, the latter are, in the majority of cases, of secondary origin, and result from the constant irritation to which the mucosa is subjected from the flow of pus over it.

Matthews' Physicians Blue Book. A complete Medical and Surgical Register of the State of Missouri. 12mo, pp. 184. St. Louis, Mo.: Lewis S. Matthews & Co., 1901.

A convenient handbook containing a list of the addresses of the legally qualified physicians and surgeons in the State of Missouri, classified by towns; a list of specialists, hospitals, sanitariums, colleges, and other institutions; State board of health; societies, medical journals, and an abstract of the medical and pharmacy laws of the State of Missouri.

Handbook on Sanitation. By George M. Price, M.D., New York: John Wiley & Sons, 1901.

This little book of three hundred pages relates particularly in its subject matter to municipal sanitation, and contains within a small compass much information which the municipal sanitary inspector is called upon to know. In its particular field it stands practically alone, and hence the reviewer is unable to estimate its merits by comparison with other works treating of the same subjects. About one-third of the book is devoted to a summary of the sanitary principles upon which house ventilation, heating, and the disposal of sewage are carried out, together with a brief consideration of the installation and inspection of plumbing. This part of the book is of such an elementary character as to be of little value for reference by the trained medical man in his work of sanitary inspection, as he should be thoroughly conversant not only with the principles and facts given in Dr. Price's book, but should also possess a much larger fund of information on matters having to do with hygiene and sanitation. The last two-thirds of the book discuss the various phases of sanitary practice as seen in large cities, the qualifications and duties of the sanitary inspector, and the several requirements of the sanitary laws of New York and elsewhere.

The chief defect of Dr. Price's otherwise excellent little work is its too elementary handling of a most important and widely ramifying subject, which cannot be fully treated in the few pages of such a book as the one in question. The author, who is well qualified to produce such a work, should now set himself to the task of preparing a much-needed reference book for municipal sanitary inspectors which shall be so comprehensive in its review of the subject of municipal sanitation, and so complete in its detail, that collateral reading may be largely unnecessary. The book is clearly written and is printed in large type. The quality of the paper used in the book, together with its binding, might be improved upon.

First Aid to the Injured and Sick. An Ambulance Handbook. By F. J. Warwick, B.A., M.B., M.R.C.S., L.S.A., Associate of King's College, London, etc., and A. C. Tunstall, M.D., F.R.C.S., Ed., Surgeon Captain, East London Volunteer Brigade, Bearer Company, etc. Philadelphia and London: W. B. Saunders & Co., 1901.

This little volume is intended to form a handbook for those whose duty brings them in contact with the injured and the sick, often before skilled professional aid is at hand. It contains enough anatomy and physiology to suffice those for whom the work is intended, and its chapters on bandages, slings, and splints are complete and well illustrated, sufficiently so for use by the student of medicine. The control of hemorrhage naturally receives full attention, and all the ordinary methods of treatment are discussed. There is a fairly complete chapter on poisons and the immediate treatment of those who have taken them. The best part of the book is that devoted to the transport of patients, and it will repay perusal. On the whole the work is satisfactory, and of convenient size—an important feature in works on such subjects.

Textbook of Pharmacology, and Some Allied Sciences (Therapeutics, Materia Medica, Pharmacy, Prescription Writing, Toxicology, etc.). By Torald Sollmann, M.D., Assistant Professor of Pharmacology and Materia Medica in the Medical Department of the Western Reserve University, Cleveland, Ohio. Illustrated. Philadelphia and London: W. B. Saunders & Co., 1901.

In the first part of this work the author treats of the preparation and prescribing of medicines, the former being a matter of concern to the pharmacist only, the latter to the physician as well. The second part is entitled "Pharmacology, Therapeutics, and Materia Medica," and is the one of chief interest to the medical reader. The author departs from the usual practice of grouping drugs according to their origin, their therapeutic or their clinical action, and follows the system of Buchheim, in which similar drugs are classed together somewhat on the same principle as that followed in the natural classification of plants. No single action nor the chemical composition determined a group, but those which have the most characteristics in common are classed together. In fact, three directions are given for practical exercise in chemical work and animal experimentation. The appendix contains a number of tables and a description of the methods of analyzing the causes of pharmacological actions. A combined analytical index and dose table completes the volume. For the ordinary student this book is somewhat too advanced, but for the older student and the young practitioner who has the laudable ambition and the leisure to ground himself thoroughly in the science of drugs and drug action, we know of no better work.

A Textbook of Physiological Chemistry, for Students of Medicine and Physicians. By Charles E. Simon, M.D., of Baltimore, Md. Philadelphia and New York: Lea Brothers & Co., 1901.

This is not a book that lends itself readily to review, for the subject of physiological chemistry is one that has been too little studied in the past by students of medicine, and in the older generation of physicians there are, we fear, few who have more than the most elementary notions of the chemical processes upon which their life and health depend. Dr. Simon's book is intended to serve as a textbook and laboratory guide, and is for that reason one that the ordinary physician can study understandingly and with profit, although most treatises on this subject will be unintelligible and profitless to him. In the first part of the work, the author gives a general survey of the origin and chemical nature of the albumins, the carbohydrates, and the fats, and of their decomposition products; in the second part, he treats of digestion, absorption, and excretion; in the third section, he discusses the chemistry of the tissues and organs of the body and of the secretions. We know of no book in which one who would inform himself in any branch of this interesting study can do so more readily than in this, and it is, moreover, admirably adapted for the purpose of a textbook for which it was written.

A Textbook on Diseases of the Ear, Nose, and Throat. By Charles H. Burnett, M.D., E. Fletcher Ingals, M.D.; and James E. Newcomb, M.D. With Numerous Illustrations. Philadelphia and London: J. B. Lippincott Company, 1901.

This volume, which is one of 716 pages, represents the work of three men, whose ability and qualifications for writing on the subjects which they have presented, are well known by the profession to be of the highest order. All are experienced writers as well as practitioners in their special branches of medicine. The book is well printed in uniform type and is fully illustrated. There are 282 illustrations in the text and 14 plates, half-tone and in color, scattered throughout the body of the book. Few of the illustrations are original, but they are well selected and serve their purpose admirably. The work is divided into three parts, namely, Diseases of the Ear, by Charles H. Burnett; Diseases of the Nose and Nasopharynx, by E. Fletcher Ingals, assisted by Otto T. Freer; and Diseases of the Pharynx and Larynx, by James E. Newcomb. Each division of the work is prefaced by a chapter on the anatomy and physiology of the part considered that is quite complete. The text is concise, but sufficiently full to render the consideration of each topic complete. The views expressed regarding etiology and treatment, whether medicinal or surgical, conform with the most approved modern ideas. The measures advised are conservative and can be safely followed. Students will find the work very helpful. It is equally well adapted to the needs of the general and those of the special practitioner of medicine.

Physicians in Germany.—The number of physicians in Germany has increased from 15,764, in 1885, to 27,374, in 1900.

Scleritis.—Avoid irritant applications, bathe the eye with hot water and instil atropin solution; touching the affected area with the actual cautery, or gentle massage through the closed lids, is sometimes beneficial. Syphilis, gout, rheumatism should be carefully attended to. Diet and habits of living must be regulated, and it might be worth while to try change of climate and the use of mineral waters.—Edward Jackson, "Essentials of Diseases of the Eye."

Treatment of Summer Diarrhœa.—W. H. Robey (*Journal of Medicine and Science*, August, 1901) says that the treatment is obviously: (*a*) To cleanse the bowel of the bacteria and their toxic products. (*b*) To give the remaining bacteria as unfavorable conditions as possible for further production. (*c*) To soothe the irritated intestine where the continuance of the condition makes this necessary. (*d*) To support the patient against constitutional symptoms, as fever, nervous irritability, etc., as in other acute diseases of childhood. (*e*) To guard against infection of others by isolation when possible, and by carefully washing the hands after handling the stools, in order not to infect other food and common household articles. Naturally, the small intestine must be cleansed by a purge, and for this purpose calomel 1 gr. was given in 1/10 gr. doses at half-hour intervals. It has been asked why castor oil was not given, since it has such soothing properties. In treating infantile diarrhœa, especially in dispensary practice, one must try to accomplish as much as possible at the first visit for obvious reasons. The gastro-intestinal tract of the infant being in an irritable state, the oil is more apt to be vomited; whereas, I have never known this result with calomel, in fact, it will allay vomiting should that dangerous symptom be present. Furthermore, castor oil is such a common household remedy that it may have been tried already, while calomel in divided doses keeps the mother busy and aids her patience in carrying out the second important step in the treatment: starvation.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Annual Meeting, January 2, 1902.

CHARLES L. DANA, M.D., VICE-PRESIDENT, IN THE CHAIR.

THE scientific programme was a continuation of the symposium on tuberculosis begun at the last stated meeting.

The Need of Sanatoria for Tuberculosis.—Dr. G. L. PEABODY was the author of the first paper, and, in his absence, it was read by the secretary. Dr. Peabody said that Europe was far in advance of the United States in its recognition of the importance of sanatorium treatment for this disease. It had been estimated that 20,000 tuberculous patients had improved under public sanatorium treatment. All the large cities of Germany had established polikliniks. After remaining in these a short time, the patients were sent to country sanatoria. It was estimated that 75 per cent. of these cases had been restored to health by means of the sanatoria treatment. In regard to the amount of exercise that the tuberculous patient should take there was the widest difference of opinion. Some writers said that exercise was the proper thing, while others advocated rest. All were agreed that life in the open air was essential, together with a climate that did not give rise to sudden changes of temperature. Exercise was contraindicated when the patient had fever. Alcohol and changeable weather were among the most important of the predisposing causes. In Germany the general hospitals were open for the tuberculous patients. Paris had special sanatoria for consumptives, and these patients who showed a slight improvement were sent to the country and given out-door work. The best results were obtained between the years of three and seven. Most of the other large cities of France were taking up this idea, as were also Canada, Sweden, Austria, Germany, and Italy. The percentage of tuberculosis to the total population had been variously estimated in different countries at one-sixth, one-fifth, and one-fourth. Dr. Peabody said that apart from the humanitarian point of view, he thought it would be better to take care of these cases in the early stages, and give them the advantages of sanatorium treatment than to let them become a public burden and care. Those who had seen the monument erected at Liberty to Trudeau knew full well what results he had obtained, and his example should be a stimulus to us all.

Dr. S. A. KNOPF presented the next paper. (See page 44.) At the conclusion of his paper, he introduced the following resolution, action on which was postponed until the next meeting under the rules:

Whereas, The Treasury Department of the United States upon recommendation of the Surgeon-General of the Marine Hospital Service has recently decided to classify tuberculosis as a dangerous contagious disease, thereby placing a stigma wholly undeserved upon every American citizen who is suffering with consumption, be it

Resolved, That the academy considers the exclusion of non-pauper tuberculous immigrants and tuberculous aliens visiting our shores unwise, inhumane, and contrary to the spirit of American justice; and be it further

Resolved, That while the academy upholds the fact of the communicability of tuberculosis, and urges all possible precautions against the spread of the disease from sputum and other tuberculous secretions or from ingestion of tuberculous food substances, the academy is opposed to all measures by which additional hardship is imposed upon the consumptive individual, his family, or his physician.

Dr. HENRY P. LOOMIS said that the crying need of New York was a sanatorium supported by the city. The condition of the tuberculous poor here was well known to physicians. These people applied at one hospital, remained over night, and the next morning were transferred to Bellevue Hospital. At Bellevue they were fed on whiskey for a day or so, and were then sent to Blackwell's Island. Here they remained for three weeks, and were then sent away, only to begin the round again. Dr. Loomis said he knew of one case that had made this round ten or twelve times in one year. What the city wanted was a hospital to accommodate these cases. On economic terms alone the taxpayer should demand such a hospital. The speaker suggested that a large stone building on the Island, which had been vacated by the Manhattan State Hospital, be used for tuberculous patients. The present administration could do no better thing than solve this problem. Four years ago Bellevue Hospital had opened a pavilion for consumptives, and in twenty-four hours it was full. Taking two years as the length of the disease, Dr. Loomis estimated that there were from 20,000 to 25,000 cases of tuberculosis in New York City. During the month of December there had been 427 medical cases in Bellevue Hospital, and out of that number 138 had tuberculosis, or about one case in three. The important feature of the sanatorium treatment was the constant care and attention to the individual case.

Dr. J. EDWARD STUBBERT of Liberty, N. Y., read the next paper. He said that one of the most important factors in sanatorium treatment was diagnosis. It was much more complete than in private practice. At Liberty every case was examined by three physicians. One examined the upper air passages, another used the *x*-ray, and the third made an examination of the excretions in the laboratory. If there was any lack of harmony in the result of the examination, the patient was re-examined. Dr. Stubbert divided the tuberculous patients into two classes, the careful and the careless. The former were much more likely to recover than the latter. It was important to educate these patients how to live hygienically, so that when they left the sanatorium they could teach others how to take care of the sputum, etc. It was necessary to build up the tuberculous cases by food, stimulations, and the like, no known drug being a specific. It was the duty of the State, as well as of the public, to establish sanatoria, but these should be free from politics and under the charge of competent physicians. Such institutions for poor working girls and others of the great middle class were a necessity. If the State did not take such action, some philanthropist should do so.

Dr. LEONARD WEBER said that poor feeding, poor housing, and changeable climate fostered tuberculosis. The great need of the thousands of tuberculous patients in New York City was a sanatorium located near the city. He was of the opinion that State aid would not be sufficient to meet the need. The time had come for the academy not only to discuss this important question, but also to take action. He suggested that the city authorities should be addressed on this subject, and that every dispensary should have a special department for tuberculous cases, in order that the early ones might be recognized, and not only helped, but cured. Sanatoria should be established at once.

Dr. W. FREUDENTHAL said that he thought all could see the necessity of having sanatoria. The use of the building on the Island, as suggested by Dr. Loomis, would hardly be sufficient to meet the demand. The great question was, What could be done for the masses? Climate was very important, but the climate of Liberty or that of Saranac was not the best. Even in Berlin some of the best results had been obtained in institutions in the heart of that city. This was due to the fact that these institutions were in charge of the very best men. He was in the habit of sending his cases of tuberculosis to the Southwest, and he thought that there was only one way to solve the problem, and that was to buy farms. In this way, "tent colonies" could be established to accommodate these patients. Some argued that the tents would be too hot in summer and too cold in winter; but this was not so, as shown by the tent treatment of typhus fever. Moreover, the farms would give the patients an opportunity to work. He did not believe in the rest cure for consumptives. Patients who were given farm work in this way would not be obliged to go back to the crowded cities.

Dr. Alfred Meyer contributed the next paper, which was read by the secretary. He said that we should not be discouraged by the results obtained in the last forty-seven years. In 1854 Peter Cooper and others had formed a society for the benefit of the consumptive poor, and while that society had been short-lived it could not be said that it had done no good. Even if the city would only take care of all the incurable cases, this would be a great boon to these unfortunate individuals. There were about 8,000 new cases of tuberculosis annually in New York City. Not all of these persons were poor though it was estimated that about nine-tenths of them were. At the present time, there were 23,000 insane cases cared for by the State, with 4,500 employees, maintained at a cost of about $1,000,000. When it was suggested that the State should care for the insane it was predicted that the State would become bankrupt. Without any doubt, New York should establish a public sanatorium for the poor.

Dr. E. H. M. Sell opened the general discussion. He said that it was most important to impress upon the patients that it was necessary for their recovery that they remain in the climate in which they had been benefited, for if they returned to their former homes the disease would recur. The speaker mentioned San Antonio, Texas, and parts of Mexico, Colorado, and California as desirable places for tuberculous persons to live. Allusion was made to a patient who had been rapidly failing in the United States, but who had been cured by living in Algiers. The village of the Nile was perhaps the poorest place of all on account of the evils arising from the system of irrigation, still some cases were benefited by living on the water. Good therapeutics was of great importance.

Dr. Edward G. Janeway said that he thought any one who had seen the effect of change of climate upon tuberculous patients could not argue in favor of the city treatment of consumption. The laws governing these changes were not well understood. Some years ago he had himself had a chronic bronchitis, which had persisted for a long time, but upon taking a trip to the western part of the State, the cough had disappeared almost in one day. This was due, he thought, to the climate. Over and above everything else climate had a great influence, and a radical change of climate was very important. One common cause for disappointment was that cases would go to the country, and while there would not have any medical care. Dr. Janeway suggested that sanatoria should be established in the country for the incipient cases, and hospitals in the cities for the more advanced ones. The offense to the neighborhood should be considered, for, here in New York, certain sections were opposed to even a surgical hospital. He felt sure that in time we would have municipal hospitals for tuberculosis, but he was not so certain that it would be this year or the next.

Dr. Louis Faugères Bishop said that he was glad Dr. Knopf had spoken of "phthisiophobia," for he thought this fear was a good thing, as it tended to force the tuberculous cases out of the crowded tenement districts to the hospitals or to the country. Mention was made of a man suffering from emphysema, who had lost his position on account of a cough, and had been unable to get employment until his cough had stopped. The public should be made to understand that persons suffering from tuberculosis should go to sanatoria and stay there. Dr. Loomis was wrong in saying that *all* tuberculous cases were sent to Bellevue Hospital, for there was a ward for consumptives at the Colored Hospital.

Dr. A. Jacobi said that it had been his intention not to speak this evening, but he wanted to call attention to the utter brutality of telling a poor consumptive to go to Colorado immediately, when that person has not enough money to buy needed food. Such unfortunates should be taken care of by the municipality. In this connection, it was well to remember the words of Holy Writ: "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto Me."

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, December 26, 1901.

A. Brothers, M.D., Chairman.

Tubercular Adnexa.—Dr. L. J. Ladinski presented this specimen, which had been taken from a woman who had given a history of slight dysmenorrhœa. Vaginal examination revealed the presence of a fluctuating tumor on the right side, slightly painful to the touch. It was diagnosticated as an ovarian cystoma. On opening the abdomen, the right side of the pelvis was found filled with a mass and a hæmatoma. The peritoneal surface of the ovaries and tubes were studded with tuberculous nodules. The diagnosis had been confirmed by the pathologist, Dr. Jeffries. The case was especially interesting because of the absence of symptoms pointing to the disease. There was nothing to indicate the mode of infection.

Ovarian Cysts and Fibroids.—Dr. A. H. Goelet presented these specimens which had been taken from a woman, twenty-nine years of age, who had missed one or two menstrual periods. The symptoms were dysmenorrhœa, dyspareunia, and frequent micturition. Operation had revealed a double cyst of the left ovary. Two small fibroids were also discovered and removed. At the first examination it had been difficult to make the diagnosis because of the resemblance to ordinary pregnancy.

Dr. H. J. Boldt presented the following specimen:

Myo-Fibroma of Ovary.—He said that solid tumors of the ovaries were of rare occurrence compared to the frequency of cystic growths. It was said that about 2 per cent. was the proportion of fibroid and fibro-cystomatous tumors. In his experience fibroid tumors of the ovaries occurred still less frequently. Histologically they did not differ from similar tumors of the uterus. It was maintained that they did not contain as much smooth muscle structure as uterine fibromata; on the other hand, a number of instances had been described in which stress had been put on the richness of muscular elements. As a rule, such tumors were well pedunculated; they might, however, have an intraligamentous development.

If a boundary line existed at all, the boundary zone merged into ovarian stroma, and the non-participating portion of the ovary then usually showed evidence of chronic ovaritis. The patient from whom this specimen had been obtained was thirty-five years old and had never been pregnant; she had menstruated regularly, but the flow was of small quantity and of only two days duration. There had been no dysmenorrhœa. She complained of pressure symptoms in the pelvis, constipation, and frequent micturition. Examination showed the pelvis to be filled by a tumor of solid consistency, not painful on pressure. The uterus was pushed upward, was apparently of normal size, and seemingly had no connection with the pelvic tumor. The adnexa could not be palpated. The diagnosis was a pedunculated fibroid of the uterus. Abdominal section revealed a normal uterus and the tumor in connection with the left adnexa. It was pedunculated and was readily removed. No trace of ovarian structure could be seen. The Fallopian tube was but slightly thickened. The right tube and ovary were normal. The neoplasm appeared pale, had a slightly nodular surface, and was of hard consistency. The dimensions were antero-posteriorly 8½ cm., 10 cm. by 17 cm. The cysts, seen upon section, contained albuminous and fatty material. It might be inferred hat they were dilated follicles, were it not for the occasional finding of fat in them. Smooth muscle fibrillæ were abundant in the neoplasm. He had just been informed that the patient had conceived since the operation. It was his belief that occasionally solid tumors of the ovary were reported as fibro-sarcomata, when they were really either fibromata or fibro-myomata.

Two Uteri Removed per Vaginam for Carcinoma of the Corporal Mucosa.—These specimens had been removed from patients fifty and fifty-one years old, respectively. Because of slight irregular bleeding or "spotting" from the genital tract, curretting had been advised. Examination of the scrapings revealed carcinoma. Because of the general condition of the patients, it was considered advisable to perform the operation of hystcrectomy as speedily as possible; hence, clamps were chosen instead of the typical ligature method. In one instance, the time taken to complete the operation was four minutes; in the other case, six minutes. The adnexa, not being readily accessible, were left *in situ.* Both patients made uneventful recoveries. In all patients whose physical condition was so much below par that it was important to complete an operation, such as vaginal hysterectomy, the clamp method should receive preference. It was indeed seldom that a hysterectomy, which with ligatures would be exceedingly difficult, requiring from one hour to one and a half hour or more, would take with clamps more than 10 to 15 minutes to complete. From the practical side, he considered the necessity to catheterize patients after clamp hysterectomies a serious objection, because, despite the greatest care used, he seldom saw a patient escape without a more or less severe attack of cystitis. Neither was the convalescence so quick or so afebrile as with the ligature method. He was of the opinion that except in cases like the ones presented, or when there were great technical difficulties, the ligature method should be selected.

Vaginal Hysterectomy for Recurrent Pelvic Peritonitis.—This uterus had been removed from a patient thirty-six years old, who, according to her statement, had been ill more than five years as the result of recurrent attacks of pelvic peritonitis. The uterus was immobile, and the pelvis filled with exudate on either side of the uterus. An abdominal section was proposed, but objected to. The profuse typical, and at times atypical, bleeding from which the patient suffered, and which aided in keeping her in such poor physical condition, must be attributed solely to the pelvic inflammation. In this instance clamps were also chosen, because the difficulties with ligatures, while not insurmountable, would have been very great. Recovery was uneventful. While the patient was not entirely free from pain, her condition had so much improved that, to use her own words, she felt like "a new-born." The exudates had not disappeared entirely.

A Corpus Luteum Cyst(?).—This ovarian cyst presented an ideal condition for conservative surgery. While the intimate agglutination of the Fallopian tube to the cyst did not permit the saving of that structure, it was possible to resect the cyst with but a small zone of the ovary. The cyst was seen to spring from a corpus luteum, so that it seemingly was, so far as the relations were concerned, a corpus-luteum cyst. Whilst this could not be settled until a microscopical examination had been made, the appearance of the cyst would not warrant such assumption, the contents appearing like those of a cyst adenoma. The situation of the cyst excluded the assumption of its being a follicle cyst. The ovary was attached to the uterus by a few catgut sutures.

Dr. Boldt said that he had no faith in the belief expressed by some authors that conception might take place from such conservative surgery. All that it did, in his opinion, was to conserve the menstrual function, which, however, was of such importance that it behooved all to practise it with this end in view whenever consistent. Were it true that conception could take place without the presence of the oviducts, our teachings in this line would necessarily have to be changed.

A Specimen of Somewhat Advanced Extrauterine Pregnancy.—Dr. A. Brothers presented a fœtus and placenta removed from a case of extrauterine pregnancy at the third or fourth month.

A Quack Method of Removing Tumors.—Dr. Brothers also presented a mass of tissue that a woman had discharged after having taken a certain quack remedy with the idea of dissolving and bringing away the tumor. Although the woman thought the detritus discharged was the dissolving tumor, examination showed the growth to be even larger than before.

Dr. S. W. Bandler said that he had only had an opportunity to make a very hasty examination of frozen sections of this tissue. This showed the presence of squamous epithelia and leucocytes, and these findings indicated an inflammatory and ulcerative process; in other words, a desquamation of the vagina.

Prevention of Cystitis.—Dr. H. Lilienthal said with reference to the remarks made by Dr. Boldt on catheterization in certain cases that he had been experimenting with various methods with a view to preventing cystitis in both men and women. Instead of waiting for the bladder to become distended in cases requiring catheterization he had had the catheter passed as often as every three hours. This method alone, by preventing stagnation of urine, often proved sufficient to cure a case of cystitis without resort to washing out of the bladder. In addition to this, he had also made use of prophylactic doses of certain urinary antiseptics, especially urotropin, giving usually four grains twice daily. Owing to faulty technique or the carelessness of nurses, this means of prophylaxis seemed desirable. He had seen no case of severe cystitis since adopting this plan.

Dr. A. Brothers said that he had had a case similar to one of those reported by Dr. Boldt, and had committed the same error in diagnosis, looking upon it as a fibroid of the uterus instead of a fibroid tumor of the ovary. He thought the ligature method was more surgical than the use of clamps, though the latter might be desirable at times.

Dr. Boldt replied that he did not favor the clamps under ordinary circumstances, and under no conditions did he approve of the use of the angiotribe.

Some Points in the Diagnostic Palpation of Prolapsed Kidney.—Dr. Augustin H. Goelet discussed this subject briefly. He was satisfied that prolapse of the kidney had been very much underestimated, and that it had been often overlooked through lack of familiarity with the symptomatology and lack of expertness in abdominal palpation. The gynecologist often overlooked it because of making the examination on the back, or in the standing position after a gynecological examination in the recumbent position. It should be understood that when the organ had been replaced it often remained in good position for some time afterward. A study of his records showed that this condition of prolapsed kidney was found in 25 per cent. of gynecological cases taken at random. If the kidney prolapsed to any extent it would be pressed against the ovarian vein which lay in front of the ureter. When this prolapse was extreme, the dragging on the vena cava probably caused some obstruction in that vein. If this pressure were constant, it would be equalized by a collateral circulation, but, as a matter of fact, it was intermittent.

Symptomatology.—The chief symptoms of the condition were stated to be the following: (1) Chronic digestive disturbances; (2) Unusual fatigue on exertion; (3) Nervousness, restlessness, and insomnia; (4) Palpitation of the heart, vertigo, and syncope; (5) Epigastric pain extending to the left of the median line over the heart; (6) Dragging pain in the loin and down the thigh; (7) Inability to rest comfortably on the side opposite to the [illegible] (6) Deficiency of the bladder; (7) [illegible] (8) Pain in the region of the appendix; (9) Pain in the region of the ovary; (10) Attacks of renal colic; (11) [illegible] of pressure of the corset or clothing at the waist.

Method of Examination.—The patient should be placed before the physician in the standing posture against a firm support and should bend slightly forward. With one hand the loin should be grasped just below the free border of the ribs, and deep pressure made during inspiration. With the tips of the fingers of the other hand placed below and making pressure upward, the kidney could be caught between the two hands. Sometimes the kidney could not be palpated until the patient coughed. When the abdominal wall was unusually rigid or thick and flabby, the palpation of the kidney could be better effected with the patient on the back and the thighs flexed upon the abdomen. A distended colon very frequently interfered with examination, as did also tenderness of the kidney and rigidity of the abdominal wall.

Dr. M. [illegible] agreed with Dr. Goelet as to the relative frequency of movable kidney in women, and it should be noted that many of his own cases were not gynecological. Movable kidney might exist without any symptoms whatever, and there were many cases of prolapsed kidney associated with digestive disturbance. The general prolapse of the abdominal organs he would not look upon as a disease, but it was of interest to the physician because of its tendency to aggravate digestive disorders or other diseased states. To the symptoms already given he would add a disposition to become tired and weak in the back on slight exertion, a dragging sensation, and frequency of micturition. Only the cases of extreme prolapse of the kidney could be detected by the older method of performing palpation with only one hand. He did not think the method recommended this evening was applicable to cases of only the second or third degree. A kidney prolapsed in the first degree was one which could be felt on deep inspiration.

Dr. A. Ernest Gallant said that when the prolapsed kidney was tender and not easily replaced, speedy relief would be afforded by rest in bed and massage directed upward along the free border of the ribs. It had been claimed on good authority that the normal mobility of the kidney was from three to five centimeters. What had been said about the number of persons having movable kidney was all right, but nothing had been said about the proportion of those who suffer from the condition. The suffering was certainly not in porportion to the degree of mobility. A kidney in the false pelvis might become adherent there, and still give rise to no special discomfort. A kidney at the waist line would, however, invariably cause distress because of its intolerance to the pressure of the corset. The most troublesome movable kidneys were those which descended only from two to five centimeters. Intolerance to the pressure of the corset or clothing at the waist seemed to him the most important of all the symptoms, though the patient would not generally mention it of her own accord. It would be found that the cord was worn unusually loose, and on inquiry the woman would say that she could not wear a tight corset. Some of the worst cases of jaundice that he had ever seen had been due to movable kidney. He had personally been able satisfactorily to examine the patients standing, but had found it better to place the patient in the reversed Trendelenburg position. With the thumb in front, one could not get up high enough in many cases to reach above the kidney.

Dr. H. Lilienthal believed that too much stress had been laid upon the mere presence of movable kidney, though undoubtedly in many cases treatment was demanded. He had noted that the very worst cases of movable kidney were those of acute displacement, the result of traumatism. Such cases could only be properly treated by operation, and if this were done sufficiently early the best results might be expected. In general symptomatology, if the patient were suffering from the displacement of the kidney, pressure upon that organ would aggravate the symptoms. He was of the opinion that with one hand on the [illegible] and the other on the abdomen, the examination would be facilitated by having the trunk at least erect. It was not always possible when there was a tumor of the kidney to say whether the tumor was connected with this organ or with some of the surrounding organs.

Dr. L. [illegible] said that all of the symptoms enumerated by Dr. Goelet he would ascribe to displacement of the stomach, with the exception of pain in the region of the ovary. He had reported three cases in which the displacement of both the stomach and the kidney had been relieved and had [illegible] until after a severe illness, when both had [illegible]. It was evident, therefore, that we should not diagnose these different displacements separately.

Dr. H. J. Boldt said it was his opinion that that method of palpation was the best which most thoroughly relaxed the abdominal muscles, and for this reason he favored having the patient in an erect posture. He did not, however, believe that the method recommended by Dr. Goelet was the best. It was his opinion that probably not more than 1 or 2 per cent. of the cases of movable kidney required surgical intervention because of the severity of the symptoms thus produced. In a goodly number of these cases he had seen a thickened condition of the appendix.

Dr. M. I. Knapp said that he had seen at his clinic in the past few months [illegible] females and [illegible] males. Of this number, 27.51 per cent. of the females and 7.[illegible] per cent. of the males had prolapsed kidney. Of the females, the right was prolapsed in seventy-six, the left in forty-eight, and both in fifty-six cases. He favored examining these patients by the method of Ewald. The patient was placed in the semi-prone position, and the examiner placed one hand at the back and the other on the abdomen. For the first or second degree of prolapse of the kidney he doubted if anything but the recumbent position would enable one to detect it. In the treatment of these cases he advocated the use of the corset made with whalebone, applied snugly but not tightly, and the clothing suspended from it.

Dr. Goelet in closing said that he had been studying the relation between prolapsed kidney and pelvic disease in women, and he cited several cases to illustrate the effect of such prolapse on the production of pelvic congestion. He thought that at least 60 per cent. of his cases of prolapsed kidney had symptoms, and that 50 per cent. demanded operation. When there was difficulty in palpating the kidney by his method, it was a good plan to compress the abdomen between the fingers and thumb of one hand at the free border of the ribs, and then instruct the patient slowly to take a deep breath. On doing this, the kidney would be felt to slip down between the fingers of the examining hand.

The Effect of Passive Congestion on the Formation of Callus.—Anton Bum describes experiments on dogs which indicate that Bier's and Dumreicher's methods of producing passive congestion about tubercular joints or ununited fractures are justified by the actual histological changes produced. The author broke both tibiæ of young dogs, and then applied elastic constriction for an hour and a half daily above the knee on one side. The animals were killed, and sections made on from the twelfth to the thirty-second day later, with the result that in every case calcification and ossification were found further advanced on the side that had been subjected to the congestion. It was principally the periosteal callus that was stimulated, the myelogenous and intermediate callus not being markedly affected.—*Centralblatt für Chirurgie.*

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, December 23, 1901.

FRANK VAN FLEET, M.D., PRESIDENT.

Osteomyelitis; Its Etiology and Pathology.—Dr. JOEL E. GOLDTHWAIT of Boston, Mass., presented a paper on this subject. He defined osteomyelitis as a suppurative inflammation of bone, due to infection of the bone by microorganisms. According to Nichols, the process had been described as a furunculosis of bone, but the inflammatory process was modified by the peculiar anatomy of bone. In osteomyelitis the process began in the marrow spaces of the bone which communicate freely with one another, so that the process might extend quickly and the products of the inflammation be retained. In a certain number of cases, however, the process might remain local, giving rise for many years to symptoms simulating joint disease. In the spreading variety the streptococcus was usually present, and in the more localized form the staphylococcus. All observers agreed that the staphylococcus pyogenes aureus was usually the organism present. Not infrequently the pneumococcus was the cause, and in such cases the onset was sudden, the invasion rapid, and the seat of the disease usually in the cancellated structure near the epiphyseal line. More frequent than this form was that variety of osteomyelitis usually following typhoid fever, and due to the typhoid bacillus. Keen had collected thirty-eight cases of this kind, in fourteen of which the bacillus had been in pure culture. In long-continued osteomyelitis with open sinuses, various organisms, some of them non-pathogenic, were present. Osteomyelitis, therefore, was not a specific disease, but an acute disease resulting from the invasion of various pathogenic organisms. The disease very commonly attacked individuals whose bones had not attained a complete development; about half of the cases reported had occurred in children between the ages of fourteen and seventeen. The disease frequently followed extreme fatigue and exposure to cold, or occurred subsequently to measles, scarlet fever, or pneumonia. Osteomyelitis often occurred after slight injuries, such as bruises or contusions of the infected bone, even without visible break of the skin. The infection of bone was often secondary to a local infection of some other part of the body, as for example, a furuncle or ulcer; sometimes the infection was secondary to some process, such as pneumonia. Osteomyelitis often appeared to be primary; indeed, in none of the speaker's own cases had it been possible to determine the point of entrance of the organism. Osteomyelitis might attack either the long or the flat bones, though most commonly the latter. It might attack the shaft or the cancellated tissue near the ends. It was almost always on the shaft side of the epiphyseal line. While osteomyelitis was commonly seen affecting the shaft of the bone, it should not be forgotten that it might attack the bones of the spine. A considerable number of persons affected with spinal disease had osteomyelitis of the vertebræ. The laminæ were probably more commonly affected than the bodies of the vertebræ. From a study of the literature, as well as from his own experience, he felt convinced that not infrequently cases of Pott's disease with abscess, which had been reported as cured without deformity, were cases in which there had been osteomyelitis. He had found radiography of the greatest assistance in locating the disease and making an exact diagnosis. A number of radiographs were exhibited in illustration of the different varieties of osteomyelitis.

Its Chemical Aspect; Symptoms and Differential Diagnosis.—Dr. ROBERT TUNSTALL TAYLOR of Baltimore, Md., discussed this part of the subject. The symptoms, he said, were those of a malignant form of progressive sepsis, as Senn had stated. The physical signs were those of septic pyæmias. The premonitory symptoms of apathy, anorexia, malaise, and exhaustion were followed by profound chill, or, in young children, by a convulsion. In this stage of invasion the spleen would be found enlarged, and the intense pain would direct attention to the seat of the local process. The greater the exudation, or the higher the evening temperature, the more intense the pain. Tenderness could be easily detected by palpation, and the point of greatest tenderness usually indicated where the incision should be made. It was usually found near the epiphyseal junction. Deep fluctuation might be slow in development until the inflammatory products had involved the periosteum. At times, the periosteum might be entirely separated from the bone, with secondary death of the underlying bone and an unusual enlargement of the adjacent bone. Forty-one cases of acute vertebral osteomyelitis were on record. The process was most common in the lumbar region. As a rule, in children the epiphysis was a barrier to the extension of the process into the joints. Serous synovitis might occur from circulatory disturbances, and not from extension of the process. Epiphyseal separation might occur suddenly, and even a pathological fracture. Should the patient survive the initial toxæmia of the acute stage, and the abscess find sufficient drainage, there would be a decided abatement of the symptoms, but a moderate fever would persist during the formation of the sequestrum. The differential diagnosis ordinarily presented no serious difficulties. The diseases which were more commonly confounded with osteomyelitis were typhoid fever and rheumatism, though sometimes tubercular joint disease, scurvy, and osteosarcoma were taken for osteomyelitis. Examination of the blood and the determination of the presence or absence of leucocytosis would sometimes assist in making the differential diagnosis. Acute rheumatism never assumed the aspect of a grave septic invasion. Hayem and Osler had called attention to the rapid destruction of the red blood corpuscles in acute rheumatism. The absence of high temperature in tubercular joint disease, scurvy, and osteosarcoma should serve to differentiate them from osteomyelitis. Radiography would, of course, clear up many cases.

Tubercular, Rheumatic, and Other Affections of the Joints; Their Etiology, Pathology, Symptoms, and Differential Diagnosis.—Dr. H. AUGUSTUS WILSON of Philadelphia, Pa , presented a brief paper with this title. He said that Dr. V. P. Gibney had analyzed 596 cases of tubercular joint disease, and had found tubercular disease in the parents in 68 per cent.; and Dr. C. Fayette Taylor had analyzed 845 cases of Pott's disease, with the result that 34 per cent. of the parents had been found to be tuberculous. In old tuberculosis the tubercle bacillus might be destroyed or no longer demonstrable. The apparent triviality of the earlier symptoms of tubercular joint disease often prevented the making of an early diagnosis. Specialists were prone to criticise the family physician for not having made the diagnosis until deformity or abscess had appeared, but the diagnosis was often made with difficulty in the incipiency of the disease. If the statements of the parents of children afflicted with tubercular joint disease could be believed, the greatest share of blame for not making an early diagnosis must be laid upon the hasty examination, or the failure to make any examination, when the case first came under observation. Reflex muscular spasm gave a characteristic expression to the affected joint, and the occurrence of night-cries should always lead to careful investigation. Two serious errors occurred so often as to require mention. One of these was examination of the joint under an anæsthetic, thus eliminating the reflex muscular spasm, and making it easy to inflict traumatism upon the joint. The striking of the heel or the knee in examining for coxalgia was a reprehensible practice, because of the trauma thus produced. The greatest reliance could be placed upon the manner in which the functions of the joints were performed, and this was to be determined by critical inspection and careful comparison with the corresponding bone. The use of classification as a means of diagnosis was fraught with danger because of the great liability to an erroneous diagnosis as a result of the [illegible] of the [illegible] these conditions. Much harm arose from endeavoring to consider hip disease with reference to the conventional three stages. These so-called stages were in reality the result of bone disease, and in no sense should be considered a part of it. Recovery from bone tuberculosis might and should be without external evidence of its existence.

The Mechanical and Operative Treatment of Such Joints.—Dr. A. M. Phelps took up this part of the subject. He said that just as soon as the pain and deformity had been overcome, mechanical treatment with splints should be employed. The theory of such treatment was to remove muscular contraction and to relieve intra-articular pressure. In the form of apparatus intended to protect a limb should extend at least two inches and a half below the bottom of the foot, and have a point of support against the tuberosity of the ischium, preferably by means of a ring. In the treatment of hip-joint disease it was absolutely necessary to have lateral traction, that is, in the axis of the neck of the femur, as well as traction in the line of deformity. After the deformity had been overcome he used the lateral traction splint, and if properly applied, it would practically prevent the limb from ever becoming deformed again. As a rule, cases so treated recovered without ankylosis. He wished to lay down the rule that no case of hip-joint disease recovered in less than two years, and that, therefore, the lateral traction splint should be worn for this period of time. After this a walking brace should be worn for at least another year. Occasionally one met with cases of apparent hip-joint disease which recovered within a few months, but these were examples not of tubercular, but of simple inflammation of the joint. For the treatment of knee-joint disease in children there was no brace better than the Thomas brace. In knee-joint disease, traction must also be made in two directions, i.e., one longitudinal and the other at a right angle to the head of the tibia. This principle should not be lost sight of when using the Thomas brace. He also made use of the Thomas brace in ankle-joint disease, the ankle being encased in plaster-of-Paris. However, for the adult he preferred a brace which he had devised some years ago. In diseases of the shoulder joint he made use of pads in the axilla and adhesive plaster straps placed around the arm in such a way as to counteract the tendency to drive the head of the humerus into the glenoid cavity. In disease of the spine the same law applied as in disease of the joints of the lower extremity. He favored the use of the aluminum corset. Regarding the treatment of the abscesses connected with joint disease, the speaker reiterated his well-known radical views on this subject. The abscess, he said, should be opened and cleaned out, the joint cavity washed out successively with pure carbolic acid and alcohol. Packing with gauze was a pernicious practice, because it tended to prevent free drainage; it was far better to make use in all these cases of glass speculum drainage. It was especially important, in his opinion, promptly to attack the abscesses of hip-joint disease. Abscesses which had discharged into Scarpa's triangle should not be opened at this point, but by means of an incision along the anterior border of the femur. In sternal disease with ulceration, occurring in children, immediate operation was indicated. If the periosteum were left, the bone would be reproduced in over 60 per cent. of the cases.

Dr. A. B. **Judson** said that he had been looking for a number of years for a short cut in the treatment of osteitis of the joints, and had come to the conclusion that there was none except in those cases which were taken in hand in their very incipiency. It was, however, almost absolutely certain that the patients, if properly treated, would recover. These diseases were, in a sense, self-limited, that is, we might regard as certain the arrival of the time when pain and destruction of tissue would cease, and give way to comfort and cicatricial repair of bone and of the other tissues. Operations had not shortened the histories of these cases. General improvement of the diet and surroundings were most promising. But in the first rank were to be placed mechanical means which relieved pain and added so much to the patient's ability to take his share of active pleasure and work. Since the general adoption of mechanical treatment the absorption of abscesses had become so common, and their behavior in general so harmless, that the question of the behavior of abscesses, formerly so serious, was now of but little moment. It was also interesting to note that remarkable degrees of functional ability were secured, and that as most of the patients were little children, their growth was of great assistance in the treatment.

Dr. George R. **Fowler** of Brooklyn said that osteomyelitis might present itself as an ordinary acute infection, as a hyperacute infection, and sometimes even as a subacute infection. In some of the cases of the last class it was exceedingly difficult to differentiate them from the ordinary cases of infection of the flat bones. The sternum was perhaps the one most likely to become involved. In his own experience, it had several times happened that a subacute infection of the sternum, in many respects simulating a tubercular process, had finally proved, on exploration, to be either an infection with the staphylococcus aureus or albus; it had rarely proved to be a streptococcus infection. It was well known that in all cases of so-called caries of the sternum considerable difficulty was experienced in securing healing after the incision and curettement, and perhaps the removal of considerable portions of bone. In his earlier experience this had been a matter of considerable difficulty. The older practice was frequently and repeatedly to curette and to pack. Some time ago he had endeavored to make use of Schede's method of obtaining the mechanical advantages of the presence of the blood clot in aiding the formation and proliferation of the vessels, and so facilitating the filling up of the cavity. Occasionally good results had been obtained. Later, he had attempted to secure the formation of clot by thorough curettement and filling of the cavity successively with pure carbolic acid and alcohol. The cavity was then filled with clot. This method had given better results than any other. In the so-called hyperacute cases the most threatening symptoms developed in a very short time. In the ordinary acute cases there was a tendency to become chronic and there was a succession of infections which might continue for weeks or months.

Dr. V. P. **Gibney** said that he had been delighted with Dr. Goldthwait's lucid paper on a disease whose pathology was so little known, and so very obscure. The subject was of great practical importance, for, in the past many persons would have been spared years and years of suffering had our diagnostic powers in this class of cases been better. He was rather disappointed that Dr. Wilson had said nothing about bovine and human tuberculosis, a subject that might in the near future assume considerable importance in connection with bone tuberculosis.

Dr. **Reginald H. Sayre** commented upon the wonderfully rapid course of some of these cases of osteomyelitis and pointed out that it was one of the most prominent points in differentiating between osteomyelitis and ordinary bone tuberculosis.

Dr. **Royal Whitman** agreed with Dr. Goldthwait that localized subacute osteomyelitis of the spine was not particularly uncommon. These cases were marked by an extremely rapid recovery.

Dr. W. R. **Townsend** said that if surgeons were called in early to see these cases of joint disease, he thought the general results would be better. It was a distinctly special subject, and did not come within the sphere of the general medical practitioner.

Dr. **Willy Meyer** remarked that not in all cases of osteomyelitis was the bone swelled; hence, in some instances it was difficult to make the diagnosis without careful search for a point of tenderness. He also pointed out that osteomyelitis of the maxilla was exceedingly common, and was the result of the lack of surgical cleanliness among dentists. It was a distressing truth that very few dentists regularly employ antiseptic or aseptic surgical methods. The speaker also said that he had used Bier's method of treatment since 1893, and thought exceedingly well of it. The method consisted in the employment of pressure by means of an elastic bandage with the object of producing venous stasis. He had found this method peculiarly useful in tubercular disease.

Dr. W. O. Plimpton said that he had met with a number of cases of osteomyelitis in which after surgical operation the healing process had not been satisfactory until antisyphilitic treatment had been instituted.

Dr. Robert T. Morris raised the question as to why, in cases of osteomyelitis, the bacteria chose for their point of invasion the very home of the phagocytes, and a time of life when the phagocytes were supposed to be the most active.

Dr. Henry Ling Taylor said that this evening's discussion showed very clearly that orthopedic surgeons were fully alive to the fact that the basis of all good treatment was a sound pathology.

Dr. Goldthwait, in closing, said that he had desired to direct special attention this evening not to the very acute cases, which were usually diagnosticated by the general practitioner, but to the more insidious ones, which were apt to lead to errors in diagnosis.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending January 4, 1902.

	Cases.	Deaths.
Measles	702	25
Diphtheria and croup	286	41
Scarlet fever	265	17
Smallpox	8	2
Chickenpox	46	..
Tuberculosis	235	139
Typhoid fever	45	10
Cerebrospinal meningitis	..	5

The Bacteriology of Schools.—Ernesto Cacace says that the study of the organisms to be found in the dust of schools, though of the highest sanitary importance, has never been cultivated as it deserves, and gives the results of a set of observations made by him in the normal school of Capua. Two sides of the question were studied, the quantitative and qualitative bacteriology of the dust, and secondly, its virulence, when injected into guinea-pigs, with especial reference to the presence of the tubercle bacillus. The organisms identified were as follows: Bacillus subtilis, Proteus vulgaris, Bacterium megatherium, Bac. mesentericus vulgatus, Bac. fluorescens liquefaciens, Sarcina alba, lutea, and aurantiacea, Bac. coli (very abundant and virulent). Staphylococcus aureus and albus. The dust collected at the end of the daily session was always much richer in organisms than that taken early in the morning, while the largest number of bacteria was always found in the room where the kindergarten classes were held. The month of June was found to be particularly favorable for bacterial growth, and this fact points toward the expediency of especial care in cleaning at this season. All of the guinea-pigs injected with larger amounts of the dust died of septicæmia, and Bac. coli and Staphylococcus pyogenes aureus and albus were recovered from their blood. No signs of tubercular or tetanic infection were ever discovered. In view of the susceptibility of the intestinal tract of the child, the presence and virulence of the Bac. coli is of great importance, and this alone should insure the thorough and systematic disinfection of all schoolrooms at regular intervals.—*Centralblatt für Bakteriologie, Parasitenkunde und Infectionskrankheiten.*

The Agglutination Reaction in Infections of Different Grades.—S. J. Goldberg has found that the power of agglutination does not always correspond to the degree of immunity possessed by the animal, and that it is not possible to take it as a measure of the power of resistance. His experiments were made upon rabbits and guinea-pigs, and two sets of investigations are described, one with the B. pyocyaneus and the other with the typhoid bacillus. The normal agglutinating power of the blood of each animal was first determined by repeated examination, and then after infection with cultures of varying degrees of virulence a further set of observations was made. It was found that in fatal infections the agglutination reaction remains unchanged, while non-lethal doses produce an increase in agglutinating power. This property, however, is variable in different animals, and is much more pronounced in rabbits than in guinea-pigs. The reaction gradually increases in intensity, reaches a maximum, and then by degrees returns to the normal again. While immunization is going on against typhoid or pyocyaneus infection, the agglutinating power of the blood increases, but is by no means proportional to the degree of immunity. —*Centralblatt für Bakteriologie, etc.*

The Treatment of Eclampsia.—W. Stroganoff, who is not an advocate of the various heroic operative measures, such as immediate cæsarian section, which have been proposed for this condition, reports that in the past four years out of 9,000 labors he has had over 100 cases of eclampsia. Of this number, six were lost, three owing to complications, and three owing to the extreme gravity of their condition when admitted for institutional treatment. Under the plan of treatment advocated by the author, the attacks rapidly diminish in frequency, the percentage of children saved is large, and the labors progress in a comparatively normal way. Narcotics are to be given as prophylactics after the first attack for a period of twelve to forty-eight hours, the most favorable results being attainable from the combined use of opium and chloral. The greatest attention is to be paid to the lungs (position, nursing, cleanliness of mouth and nose, oxygen, cupping) and heart (physiological salt solution in the rectum, fluids by mouth, digitalis). All excitement must be spared the patient, and delivery be hastened by operative means if the procedure does not endanger mother or child. —*Centralblatt für Gynäkologie.*

Yellow Fever in Bermuda.—Dr. Eldon Harvey, Medical Officer of Health, Hamilton, Bermuda, in his report for the year 1900, makes some interesting remarks upon the connection between mosquitos and yellow fever. He says: "After carefully reading the ancient records and the histories of the epidemics in Bermuda of 1864, '56, '53, and '43, and especially those of 1864 and 1856 in the light of the recent investigations and discoveries in Havana, one is very forcibly impressed by some of the following facts: It was noticed that the disease seemed to follow the course of the wind; mosquitos go with the wind. Many instances of a cessation of the disease with fresh outbreaks some twenty days after can be found in these reports. The marked interval of time between the first cases and the general outbreak of the disease seems to correspond with the time required by the parasite of yellow fever to undergo a definite cycle of development in the body of the mosquito before she is capable of conveying infection. Improvement was shown by fever cases occurring among troops when they were encamped in exposed and windy places. Mosquitos do not like strong wind."

Discharged Soldiers.—From India the British Army report for 1899 reads: There were 968 men discharged in the [illegible] as [illegible] for further service, the equivalent rate being 14.[illegible] per 1,000, which is below the previous year's rate by [illegible] and the average by [illegible]. The principal causes of discharge were: Dysentery, 22 cases, or [illegible] per 1,000; malarial fevers, 14, or [illegible] per 1,000; tubercular diseases, 90, or 1.14 per 1,000; secondary syphilis, 194, or 2.38 per 1,000; gonorrhœa, 10, or .12 per 1,000; rheumatism, 21, or .41 per 1,000; debility, 36, or [illegible] per 1,000; nervous affections, 140, or [illegible] per 1,000; diseases of the organs of special sense, 90, or 1.13 per 1,000; diseases of the circulatory system, [illegible], or 2.83 per 1,000; diseases of the digestive system, 42, or .52 per 1,000; diseases of the organs of locomotion, 37, or .46 per 1,000; and injuries, 62, or [illegible] per 1,000.

The Causation of Cancer.—With reference to the article published in the *Lancet*, December 7, by Dr. Braithwaite, claiming that excess of salt was a probable factor in the causation of cancer, another British physician of note has taken the opportunity in the same journal of December 14 to support the theory. Nevertheless, there are no firm grounds for a belief that salt has any effect on the origin of the disease. One contention advanced by Dr. Braithwaite in favor of his statements was that the Jewish race was very much less liable to cancer than the Gentile race, on account of the fact that they consumed no pork, and less meat generally.

This assertion has been contradicted by several authorities. We ourselves do not think that Dr. Braithwaite's views will bear the test of a close investigation.

Professor Simpson on the Plague.—Professor Simpson, one of the best known authorities on the plague, and who has been sent out by the British Government to India to conduct a series of investigations bearing on that disease, has contributed to the *Lancet*, December 14, an article dealing with the system of harbor inspection at Bombay. He contends that the manner in which this work is carried out is thorough in the extreme, and could scarcely be improved upon. Professor Simpson also recommends that the Indian treatment of quarantine patients might be with advantage copied by France and Spain, the two nations which complain most bitterly of the ineffective measures used by Great Britain, to check the spread of plague.

Salt and Pepper.—Condiments generally, and especially salt and pepper, have a real and distinct value, outside their use in bringing out the flavor of the food, to which they have been added.

The *Chicago Tribune* points out that in eastern countries the condiments such as pepper, are used to profusion in all foods. Gastric troubles common enough in other countries are conspicuously absent, and the free use of pepper has much to do with the fact. Salt and pepper work against fermentation.

One of the best remedies for a disturbed digestion is hot water, to which has been added salt and paprika. Certainly there is no question that salt is a very valuable constituent of food.

Epoch-making in Typhoid.—The following may be considered epoch-making events in the history of the advancement of our knowledge of typhoid: (1) The hippocratic grouping of typhic diseases in the fifth century, B. C.; (2) The differential description of Galen in the second century, A. D.; (3) The doctrine of contagiousness by Fracastori in the sixteenth; (4) Recognition of the nervous involvement (Willis) in the seventeenth; (5) Nosology based upon morbid anatomy (Röderer) in the eighteenth, and in the nineteenth; (6) Description of the true nature of typhoid by Louis (1829); (7) Its complete differentiation from typhus by Gerhard and Pennock (1837); (8) The discovery of the typhoid bacillus (1880), by Eberth and Koch.—*Maryland Medical Journal.*

The Value of Sanatoria for Consumptives.—Professor E. Von Leyden, writing in the *Wiener klinische Rundschau*, 41, on the recent Tuberculosis Congress, considers that the question of "prevention" was dwelt upon too much, and that not sufficient acknowledgment was given to sanatoria in the treatment of the disease. Professor Leyden was himself one of the first advocates of sanatoria. There were in Germany at the end of 1900, 49 public sanatoria and 16 private institutions with [illegible] beds, capable of treating about 20,000 consumptives a year; of these 20 per cent are cured, and a still larger proportion receive marked benefit.

Contribution to the Pathological Histology of Leprosy.—[illegible] from his researches concludes that the leprous cell of Virchow is merely a degenerated endothelial cell filled with bacilli, with atrophied protoplasm and nucleus. It is eliminated by the subcutaneous glands, and may be a cause of contagion by that means. In the leprous process there may be the formation of giant cells. If bacilli are found in the blood vessels there may be profound alteration of the red blood corpuscles with the formation of abundant quantities of pigment. There is a visceral form of leprosy in which the nervous lesions are found only in the intramuscular branches of the nerves.—*Giornale Internazionale delle Scienze Mediche*, 1901.

Health Reports.—The following cases of smallpox yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended January 4, 1902:

PROGNOSIS: ITS THERAPEUTIC VALUE.[*]

BY HENRY FREEMAN WALKER, M.D.,
NEW YORK.

THE relation of the physician to his patient has three bearings.

First, he is expected to make a diagnosis of disease. Second, he is asked for a prognosis. Third, he guides the patient on the way to recovery, or smooths the downward pathway to death.

It is of the second division of this triple relationship that I write, as I believe it to be, in some respects, the most important to the patient.

A large and successful branch of our profession ignores the necessity of a careful diagnosis of illness, being content with the symptoms apparent, and regarding them, rather than the changes underlying them, as the object of treatment.

Other sects, not recognized by the medical profession, but increasingly strong in their following, ignore both diagnosis and treatment, and rely wholly on prognosis as the means of relief. To this class belong the Mental and Christian Scientists, Faith Curists, *et id omne genus*. In this course, they are not lacking in worldly wisdom.

Among better educated physicians, one rarely hears the phrase "curing a disease." It is so widely recognized that acute diseases are self-limited, and that the majority of them tend to recovery. The Homœopathists helped markedly in the establishment of this fact by treatment with high dilutions, and the more recent sects go yet further and show that the same results may follow with absolutely no treatment. This demonstration ought to be of value to us. Chronic diseases persist with, perhaps, change of phase, in spite of skilful management, to the end of the chapter. Alleviation is what is there expected as best result. But though a cure is not claimed, the victim can be helped by care and stimulated to self-help by a prognosis which shall give courage.

The inquiry always existing in the mind of the sufferer, and often put to the physician, is: "Am I going to get well?"

A tactful doctor, if he can speak the good word, does not wait for the question, but, as first advice, gives the encouraging answer, and the patient is started healthward by the word itself.

The tendency, aside from keen discrimination, to make a favorable prognosis is partly due to natural temperament. The sanguine man, if a physician, is sanguine with regard to his patient. To another type the reason for making an unfavorable prognosis is grounded on fear that blame will follow if anything disastrous should happen, and its probability be unannounced. Another is due to a yet lower grade of thought. If a patient recover after an unfavorable prognosis, the greater credit will redound to the practitioner.

To this class belong the instances where we hear of the physician saving a patient from typhoid fever or preventing pneumonia. The typhoid fever certainly did not exist, and the pneumonia possibly. But both are sufficiently alarming diseases to make families grateful if they do not develop. Again, it rejoices some patients to have been given up by the doctor and to be able to tell the fact. They think they have outwitted death.

The relationship of the doctor to a patient and to the patient's family is wholly different. It is the physician's duty to give the most favorable prognosis possible to the patient as a part, and the initial part, of treatment. If he errs, let it always be toward the favorable side.

To the family he may disclose his fears, and dwell more on the hazards of the illness, but to the patient it must be hope and assurance.

The consultant or the specialist is always compelled to give a prognosis more definite than the family doctor; he, in people's minds, holds the life or death verdict, and to the patient the effect is often like that of a sentence.

The mental scientists and faith curists, to use a lawyer's phrase, enter a demurrer against disease and the "what-of-it" helps scores of people to recovery.

A reason, on the positive side, for making prognosis favorable is because we can never be sure of one element in any given case, and that is the personal equation, which makes each individual unique. There is as much difference in men, as to vital strength, as there is between the cat and the guinea-pig.

There are stages in all chronic diseases where the only prognosis demanded is that of time. But a habit of toleration is acquired by a sufferer, and an onslaught of illness which would annihilate a robust person is endured by the chronic invalid without disaster.

Two large classes ought never to be given up, even in the physician's own mind—the very young and the very old. The laws of life do not apply to them as they do to those in active life; so little is needed to preserve life in the infant, while the vitality of the very old has already proved so tenacious. As example, during last winter, I saw, with a friend, an old lady of seventy-eight. She had pneumonia of great severity. Though there was extensive solidification of the lung, my prognosis, based on her age and attendant vigor, was favorable. The case progressed to complete recovery. Another, of ninety-one, had an equally good experience. Had they been sixty-eight, I should have felt less confident of the outcome. In all cases of pneumonia of the very aged my expectation of recovery is increased rather than diminished by the very fact of age.

On the other hand, an infant pinched and sunken with an exhausting diarrhœa, with pulse so flickering that one hesitates to move it on its pillow, may rally in a half-hour's drive from its city home to the seashore.

In the chronic diseases of the chief organs of the body, the heart, lungs, and kidneys, a prognosis is often most difficult. We know what the patient will die of, if he only live long enough. But we see many cases where a man has been a victim to disease of one, perhaps more, of these organs, whose taking off is by something radically different.

The man expected to die of Bright's disease has sudden death, a prognosis that tore the sufferer with the fear of an imminent fate and the life of the [illegible].

---

[*] Read at the meeting of the Practitioners' Society, December 6, 1901.

In such cases, if an unfavorable prognosis had been given, every remaining day would have been made more miserable, perhaps shortened in fact. The sufferer would have lived a life of terror. It seems that we do the best to save life.

Every one has had experience with those who dread a frank statement with regard to the condition of the heart and who fall in a fright if told the truth, and for this reason the popular belief is that heart disease is an essentially fatal disease and followed by sudden death. The prognosis of the life insurance companies has had much to do with this, more even than the [illegible] or items for the daily journals. The insurance companies have rejected many candidates because of anything the matter with the heart. Of late they have begun to realize that all organic cardiac changes do not indicate disease that immediately threaten life.

I have a patient who has an imperfect heart from rheumatism. He has slight aortic obstruction and decided mitral insufficiency, but he has a well hypertrophied heart which does its work efficiently and is likely to do so till general vigor declines with age. He, knowing the facts, applied for an endowment policy. The examiner inclined to advise granting the policy, and did so after writing me. I think my friend, a man of good habits, in active professional life, a cyclist and a golf player, runs only the risk of acute intercurrent disease, for the present at least, though I suppose, he runs more risk than another that the intercurrent trouble may be rheumatism.

Another friend with cardiac distress on slight effort received from his physician, for the time being, a most unfavorable prognosis. His temperament could not bear it. With a greater knowledge of the man's habits I was able to give a better promise, and he is now, after several years, an active man of business. He has learned prudence, but is not a valetudinarian.

In a heart with loud murmurs, but increased size and strengthened beat, so long as the blood stream is retained within its bounds, and there is no show of tissue weakness in the way of dropsy, I think one can always give the patient a good prognosis—that is, a prognosis of continued life. It is death that the sufferer fears most. We can admit disease, but say, "What of it?"

There is the subtler change that gives trouble, when a man has a little discomfort, an annoying dyspepsia, perhaps with slight nausea, some shortness of breath. Then life may be stopped by a sudden effort or a strong emotion. Oftentimes such a man has not had sufficient discomfort to consult a medical adviser.

Among the forms of heart disease, one that gives great discomfort to the patient because of rapid and violent action of the heart, is that due to adherent pericardium. To the doctor's ear the sounds are strangely mixed and confusing. There are all sorts of sounds, and only perhaps when the heart is quietest can a slight friction be detected. I never listen to such a case without being impressed with the heart's action being like that of a bird inclosed in the hand and beating its way to escape.

I believe many of our cases of persistent tachycardia are due to slight pericardial adhesion.

And yet, with all this disturbed action, the prognosis as regards duration of life is good. The heart lasts, though apparently driven by whip and spur.

I have a man now under observation who suffers from this condition. He is past sixty and in childhood; he tells me that in the violent exercise of the playground he would fall exhausted. But he lived and is not even now an invalid, though his heart's action is always violent and erratic.

In children one often finds marked signs of organic affection of the heart which the child not only bears well, but outgrows.

In these cases the best guide to prognosis is the child's nutrition. If the child continues to grow normally, a favorable prognosis can be given. If general growth is slow, or in part arrested, the outlook is bad.

In chronic trouble with the lungs, comparatively, the most favorable opinion can be given where it is most needed. It is the man who has some incurable disease who is in most need of cheer. The man with one lung useless and the other diseased is often perfectly confident of recovery.

In Bright's disease I think we should be guarded in our prognosis against unfavorable opinions.

The name to the laity carries death in its sound. But there is so large a group of diseases under the one head that discrimination must be intelligent.

The acute forms from the poisons of malaria, grippe, scarlatina and the progress of pregnancy so often disappear completely that a favorable prognosis is in order there.

And in chronic types it is not necessary to discourage a patient wholly.

In older people, in whom the changes in all tissues have begun to be retrograde, a certain degeneration of the kidneys is to be expected. The presence of a few casts and a trace of albumin, though definable by book as Bright's disease, is not sufficient ground for so naming it to the patient. He would be much more harmed by the name than by the disease. If told that the action of the kidneys is normal for his time of life, he is saved anxiety, while guidance can be given which will aid him. But if impressed with the notion that he has Bright's disease, however slight, he is made an invalid. He will watch his urine, and usually, in spite of treatment, these minor symptoms will persist, while health is impaired by the effort to thwart nature's method of slow change.

A case of Bright's disease which occurred early in my practice made a strong impression upon me. The man was a wealthy brewer. All the habits he had were bad. He had an enlarged liver. He had general anasarca. His urine, heavily albuminous, in the microscopic field was crowded with every discovered variety of casts, and yet this man, relieved by treatment of many troublesome symptoms, but not of the disease, without reform of his habits of life, lived for eight years tolerating the kidney lesions.

This experience, though I name it singly, was to me a revelation of the tolerance of disease, and has ever since been of advantage by giving courage, if not confidence, in similar cases.

Practically, a favorable prognosis does not interfere with proper guidance of the sick man.

If I know that a man who is ill with pneumonia or typhoid fever has essential business to do—perhaps has not made a will, where a will is very important—it is easy to tell him that these things should be done now to avoid accidents, and to have no cause for worry which might thwart his progress toward convalescence. In the same way, the rites, even the extreme rites of the Church, may act favorably. The mind at ease, both body and mind can rally.

I close as I began. Prognosis should be regarded as a part of treatment.

The most favorable prognosis possible should be given the patient, first, because we cannot be absolute in our own knowledge, and, second, positively for the patient's good. We have no right to shorten life an iota by adverse judgment.

THE PATHOLOGICAL AND THERAPEUTIC ASPECTS OF THE EFFECTS OF THE RÖNTGEN RAYS.

By CARL BECK, M.D.,
NEW YORK.

THE peculiar integumental changes which manifest themselves in some cases after exposure to the Röntgen rays naturally suggest that they are due to a specific influence. That they are in fact not caused by simple electric discharges, but are of their own kind, needs no further discussion nowadays.

It is only partially explained in what manner this specific influence, sometimes resulting in burns, exerts itself. Analogous to the integumental changes produced by sunlight, heat, caustics, and acids, it is largely dependent upon the strength and the amount of the Röntgen rays. The tissues are influenced differently by different rays, just as the photographic plate is impressed differently by various kinds of light. The sensitized coating of a photographic plate not only reacts the more intensely the stronger and longer it is exposed to the light, but it also shows different impressions, according to the different refrangibility of the rays. Thus the solar spectrum, even in long exposure, scarcely affects that portion of the plate where red is projected, while the blue and violet light leaves intense impressions. Green and yellow light produces stronger impressions than the red. The more refrangible the rays are, the more they are absorbed by the bromide of silver of the photographic plate.

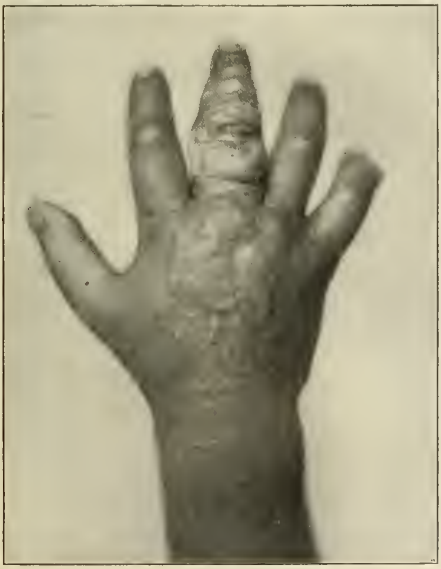

FIG. 1.

By comparing the human integument with a sensitized plate or a fluorescent screen, we learn to appreciate the specific influence of the rays on them.

We may, as in ordinary burns, distinguish three different degrees. The first degree is characterized by the symptoms of hyperæmia. Epidermis and cutis are infiltrated, and their temperature is somewhat higher. Exfoliation takes place in small scales. The most pronounced subjective symptom is a tormenting itch in the skin. Effluvium capillorum, which manifests itself, as a rule, without showing any visible signs in the integument, belongs to the same category. It seems that there is a regressive metamorphosis (atrophy) of the differentiated elements of the skin, viz., the glands, hairs, and nails.

The main feature of the second degree consists in the formation of blisters, the clear or yellowish contents of which lift the corneal from the mucous stratum of the rete Malpighi (Fig. 1). The inflammatory signs are well pronounced, the tension considerable, and the pain intense accordingly. After the removal of the blisters the corium is exposed as a red and sore surface. (Bullous form of Röntgen-ray dermatitis.)

The third and gravest degree is characterized by the escharotic destruction of the irradiated tissues. They show the signs of dry gangrene, and their appearance is brownish-black. If they exfoliate by a slow suppurating process, or if they are removed, as they should be, by surgical interference, a granulating ulcer remains, the cicatrization of which may take months. (Necrotic form of Röntgen-ray dermatitis.)

The most characteristic difference between ordinary burns and the integumental changes produced by the Röntgen light is the fact that the latter do not manifest themselves before the lapse of a period of incubation, as a rule, after about two weeks.

This stage, which we may properly call the latent, lasts about ten days in the simple type of Röntgen-ray dermatosis. Then the integument becomes hyperæmic. At first there is light, later dark, redness, and finally the skin becomes brown and scaled. After a few weeks there is complete recovery. Sometimes slight pigmentation of the integument remains.

In the bullous type of the Röntgen-ray dermatitis, after an incubation of about two weeks, intense reaction takes place. This is of a subjective as well as of an objective character, and lasts about as long as the period of incubation. Then cicatrization takes place. If the area of the irradiation was covered with hairs, depilation occurs. The process of regeneration of the hair is slow. Pigmentation and teleangiectasis nearly always remain.

The necrotic type of the Röntgen-ray dermatitis, as a rule, develops itself a few days later than the bullous form, and requires months for its cure. This type reminds one of the stationary form of gangrene, which is known in Europe as "glacier gangrene." The antediluvian face of the old inspector of the ice-grotto at the Eiger glacier in Switzerland, well known to many medical tourists, affords a study of this interesting kind of tissue change.

At some of this year's congresses I had an opportunity of studying the terra-cotta-like hands of some Röntgophilic colleagues, which presented the chronic type of Röntgen-ray dermatosis. The integument was wrinkled, shriveled, vulnerable, and partially cracked; the nails horny and also cracked, and the phalanges so much thickened that there was tension when motion was exercised. The elasticity was lessened and the sensibility increased. Effluvium capillorum was an invariable companion. Undoubtedly there was a cumulative influence. Fig. 2 illustrates this chronic type of Röntgen-ray dermatosis on a tubercular knee after the twenty-fourth irradiation.

In studying the effects of the Röntgen rays on the integument, and trying to draw conclusions for therapeutic indications—in other words, to understand their physiologic significance, we must begin with a careful clinical observation of the various kinds of Röntgen-ray dermatitis.

The details of the changes which take place in the deeper tissues of the body while permeated by the rays will be considered later. It may be said, however, that a series of clinical types have been observed resembling those of sunstroke, as the consequence of moderate irradiation, the predominating symptoms being giddiness, vertigo, palpitation, headache, and vomiting or colicky pain.

But sufficient proof of a relation between cause and effect still remains to be furnished. Such reports, indeed, remind me of a humorous episode of my student days. Soon after a demonstration of the Leyden jar, one of our comrades, who had served as a link in the chain of the electric circuit, took sick from colicky pain and diarrhea after having felt the electric shock. The incensed father appeared and assailed our good professor, declaring it was an outrage to administer such a mysterious power in a manner so utterly reckless of consequences. *Post hoc, ergo propter.* The father became pacified when he learned that a few hours before receiving the electric current his son had swallowed three pounds of cherries with their stones.

In long irradiation, of course, changes of tissue are to be expected.

Since February, 1896, I have made over 10,000 examinations with the rays; among them are nearly 5,000 skiagraphic exposures, and until a few months ago I could pride myself on never having burned any of our numerous patients, some of whom were in a rather precarious state. In my treatise on fractures I reported two cases of effluvium capillorum. In both instances the skull was irradiated often and in short intervals. Both individuals were blond. In one of the cases depilation began after the fifth, and in the second one day after the sixth, exposure. After three weeks complete restoration had taken place. No disturbances of any kind remained.

In spite of the freest manipulation of my armamentarium I was never affected by the rays myself, so that I was inclined to imagine at last that I was blessed with a certain immunity. But one day, after handling powerful tubes in connection with high electric powers, I noticed an intense burning sensation at the dorsum of the right hand, the surface which I used to turn toward the Röntgen tube while the strength of the light was tested through my own wrist. The burning sensation was accompanied by a most distressing tension, which was intensified by every motion. At first the hand appeared erythematous. Later on it became terra-cotta-like, and then the epidermis exfoliated in small scales, so that it resembled leather (parchment-like skin). Perspiration ceased entirely. During the sultry days which last summer brought in such an unwelcome number the distress was especially great. This I would explain from the desquamation which rendered the hardened follicles functionless. I then substituted the left hand for the fluoroscopic control, and protected the right one with a tinfoil glove. The violent symptoms disappeared. Soon, however, the same signs developed at the dorsum of the left hand in a somewhat milder degree, so that I was finally constrained to complete abstention from the Röntgen rays. Since restricting myself to the most necessary manipulations only, and observing a fair distance from the tube, so that fluoroscopic control can be dispensed with, no disturbances have been felt by me, and the appearance of my hands is again perfectly normal.

About the same time I observed the first case of the bullous form of Röntgen-ray dermatitis in a man thirty-eight years old, who in the course of two years had to submit to five thoracotomies for pyothorax. In view of the thickened pleura which lined the immense pyothorax cavity, I had resorted to pleurectomy, and a few weeks later the Röntgen rays were expected to give information as to the extent of the cavity, as well as of the rib-resection.

At first soft tubes were employed, the use of which gave but little contrast. Although a large pleural portion was removed, still a considerable part of thickened pleura remained. This and the fact that some of the ribs showed signs of regeneration veiled the image of the ribs. After having repeated our unsatisfactory efforts seven times, I resorted to hard tubes, which gave a better picture, but at the same time seemed to be responsible for the development of a bullous dermatitis. The incubation had lasted ten days; the skin was bright red at first, then dark red. Later on a blister of the extent of a large hand formed, the contents of which consisted of alkaline serum. After the blister was removed an excoriated surface was exposed, which cicatrized under a xeroform dressing in three weeks. Fig. 3 illustrates the pigmented integument, and indicates the persistence after two months of a few teleangiectatic areas. The patient is of blond complexion.

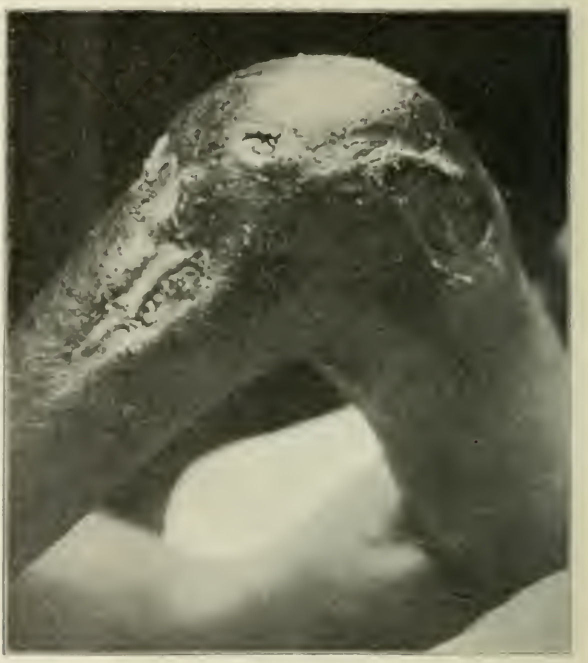

FIG. 2.

Shortly afterward the same accident happened in a blond man twenty-five years old, who had suffered from traumatic lung abscess for three years. In trying to measure the various distances of the walls of the cavity, five exposures were made. Thirteen days after the last exposure a blister of the size of a man's palm established itself at the anterior thoracic wall, opposite the opening of the cavity.

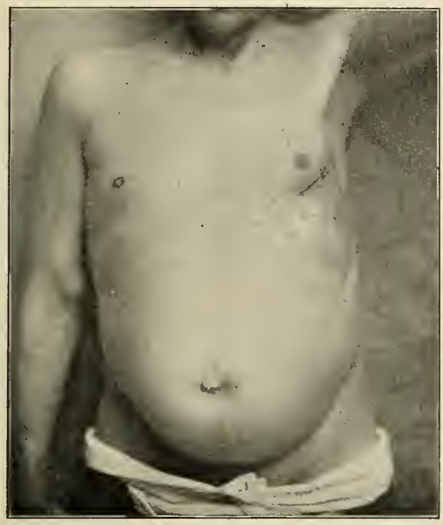

Fig. 3.

The contents of the blister were serum of light-yellowish color. After the opening and removal of the blistered tissues a superficial non-suppurating excoriation remained, which cicatrized under the application of a 10-per-cent. xeroform-lanolin ointment. Fig. 4 shows the excoriated surface three days after the first symptoms of the dermatitis had appeared.

A third case concerned a boy of twelve years, who, after having sustained a fracture of the anatomic neck of the humerus, was irradiated nine times. The difficulty of retaining the small displaced fragment in correct apposition necessitated frequent control, to which I feel justified in attributing the blameless result. Several irradiations had taken place through the thoracic plaster-of-Paris dressing, which had to be used for six weeks. After the fifth week folliculitis developed around the axillary pad. After seven weeks, eleven days after the ninth exposure, the bullous type of Röntgen-ray dermatitis developed at the infraclavicular region to the same extent as is shown by Fig. 4. Recovery was perfect in two weeks. The patient was blond.

In the first two cases, individuals were concerned the vitality of whose organs was lowered by exhaustive processes which had lasted for several years. In both instances suppurating cavities were irradiated with powerful tubes which seem to be apt to impair the resistance of the superimposed structures. In spite of this fact pathologic changes manifested themselves only after many and prolonged irradiations.

In the third case, the long-continued influences of the plaster-of-Paris dressing in connection with the axillary folliculitis were sufficient reasons for the lowering of the vitality of the integument.

Does, in cases like these, an idiosyncrasy exist? This has not yet been proven. Clinical observation makes it probable; so also does my own immunity, lasting for more than five years, when considered in contrast to the dermatoses which supervened in others after a few months only of exposure. Blond individuals seem to be especially predisposed, all our affected patients (except myself) having been blond. We may also assume that children, weak individuals, and patients like those described, react quicker and more intensely. It seems, also, that certain regions of the body are more susceptible in this respect than others. No doubt, the prolonged influence of the Röntgen rays is able to produce a more or less intense hyperæmia in any part of the human body. In experiments of long duration conducted by reliable investigators, not only hyperæmia and swelling of the conjunctivæ, but also retinitis and contraction of the pupils were observed. Thus we can readily understand that hyperæmia may also take place in internal organs, if the powerful influence lasts long enough.

It has been sought to approach this important question by experiments on the lower animal. Thus Tarkhanoff (*Gaz. degli ospedali*, March 4, 1897) observed that irradiation of the cerebral hemispheres of the frog inhibits reflex. The color of the batrachian integument appeared much darker when, after being irradiated, the frogs returned into their moist element. After prolonged irradiation of frogs, mice, guinea-pigs, rabbits, and birds, they died mostly under paralytic symptoms.

That the Röntgen rays display a powerful influence upon the action of the skin, upon metabolism and the temperature of the blood, has been demonstrated by Lecercle. In one of my experiments made on dogs, alopecia of the area, which was irradiated intensely for three hours, developed as early as on the fifth day. The hair-bulb showed no atrophy, but the epidermis and the skin-follicles were destroyed. Microscopic examination of an excised integumental fragment manifested the usual signs of inflammation.

Of the experiments on mice I am making at the present time, I may report, that depilation began on the fifth day on an average, when irradiation was done three hours a day. The first symptoms usually appeared at the forehead. During the time of observation the animals showed no disturbing symptoms—only one among nine died after being exposed to the Röntgen light for twenty-three hours. This mouse was irradiated one-half hour daily for one week, one hour daily for a second week, and two hours daily for the third week. Depilation began over the dorsum then. Soft tubes had been used for this case exclusively. The autopsy showed slight congestion of the viscera. Microscopic examination revealed the general signs of inflammatory changes. In two of the animals which were treated in the same manner, but

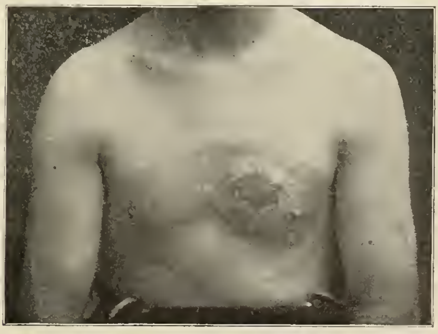

Fig. 4.

where tubes of high vacuum were used the integumental changes were slight, but the viscera, especially the intestines, were much more hyperæmic. A more extensive report on these experiments will be published shortly.

So much for observed facts. The question how these inflammatory processes are originated cannot be easily answered, because it touches not only the broad field of physics and chemistry, but also biophysiologic pathology, and even bacteriologic features. It seems to me, however, that it can best be answered on the basis of clinical observation. While the experiments on lower animals are extremely useful for comparison and suggest new ways for investigation on the human body, they cannot be conclusive for the pathology of man. The thick hairy coat of the animal reacts differently upon burns from the human integument. The same must be considered in connection with the effects of the Rontgen rays upon the skin. It will, therefore, be more proper to compare our knowledge on the conditions produced by ordinary human burns with those caused by the Rontgen rays. Here, as well as there, a disturbance of nutrition in the walls of the blood vessels and their consequences become at once apparent. By considering, for instance, the consequences of a simple burn of the second degree, it will be found that the destruction of the red blood-corpuscles, as it is described by Fraenkel, Lesser, Pawlowsky, Ponfick, and Wertheim, is of no significance even in extensive burns of this kind. According to Hoppe-Seyler, even in fatal burns of the second degree the maximum of the destroyed blood-corpuscles did not amount to more than 2 per cent. to 4 per cent. But the products of this pathologic disintegration of the tissues are much more detrimental. According to Fraenkel they originate in the same manner as during the process of digestion of albumen. The albumen is split, absorbs water and is finally transformed into albumose and peptones. Krehl and Mathews examined these disintegrated products of the albumen in the human body. From the results of their investigations we may conclude that in burns of the second degree the change of the tissues produces, besides destruction of the red blood corpuscles, disintegration of albumen. The consequence of this latter and most important change is the formation of exudates, which during the process of absorption produce albumoses. And albumose, being a product unfit for assimilation, is eliminated by the way of the kidneys.

On the various degrees of toxicity of these substances the greater or lesser severity of the clinical symptoms seems to be dependent. They also explain the fatal outcome of extensive surfaces of burns of the second degree. In addition, the loss of fluid (blood plasma) must be considered, which is the larger the wider the burned surface extends. The waste of fluids impairs the natural resistance in the organism, so that the toxic products described find a more favorable soil.

These considerations suggest, by the way, the necessity of the subcutaneous injection of saline solutions in extensive burns, which should suffice to compensate the loss of fluid.

In burns of the third degree the destruction of the red blood corpuscles is of much greater importance, since the elimination of a large quantity of them is the equivalent of carbonic-acid poisoning. To this condition, absorption of the products of the disintegrated tissue (toxæmia) is added. This brings us near the question of wound infection.

I take this opportunity again to call attention to the fact that burns are wounds, and must be treated on the same principles. For years I have advocated the immediate removal of blisters in burns of the second, and the speedy excision of the mortifying tissue in burns of the third degree (see "Ueber die Behandlung von Verbrennungen," *New Yorker medicinische Monatsschrift*, May, 1891). I am well aware that the latter procedure involves technical difficulties, but it is the only treatment which answers true surgical principles.

After prolonged over-irradiation the same signs may be produced in various degrees. The death of some of the irradiated animals alluded to above was caused by loss of plasma in the bullæ and by septic absorption in the necrotic tissue.

The main difference between an ordinary burn and the changes of tissue caused by Röntgen light consists, as already said, in the slower development in the latter case, of the process. The peculiar chemic influence of the Röntgen light on the tissues is so exerted that the nutrition of the cells is impaired. It is only when the impairment has reached a greater degree that the signs described above manifest themselves. And these signs are again influenced by the power and amount of the Röntgen light. A greater or lesser susceptibility has also significance.

Effluvium capillorum is explained by inflammatory processes in the matrix cells.

From these pathologic considerations, rules may be deduced for the therapeutic utilization of the rays, just as from the study of the deleterious properties of the poisons in their maximum doses, in order to establish their therapeutic indication and dosage.

The most obvious therapeutic application was that for hypertrichosis. In fact, irradiation has become the treatment *par excellence* for large-haired surfaces. It is only for small areas that electrolysis or galvanocautery should still be recommended.

Since the cure of sycosis is mainly dependent upon most thorough depilation, the beneficial influence of the rays can be well appreciated in this obstinate disease.

Favus, eczema, psoriasis, rosacea, acne vulgaris, and prurigo are also amenable to treatment with Röntgen light. Kuemmell succeeded as early as 1897 in curing lupus by the Röntgen light. He was soon followed by Albers-Schonberg, Hahn, Schiff, Freund, Ziemssen, Muehsam, Holland, Schenkel, Jutassy, and Neisser. In all their cases at first an inflammatory reaction was observed, followed by the drying up of the nodules. The cicatrization of the lupous portion, which was changed into a fresh granulating surface, took a considerable length of time.

I reported on my cases in previous publications, and will only add that the cure of our first patient has remained permanent now for three years. (*Deutsche Medicinalzeitung*, 1900, No. 51.)

The nodules usually shelled out together with the destroyed tissue. In their place a light red ulcus remained which bled on the slightest touch. In one case the nodules shrank and showed a terra-cotta-like appearance.

Cases of lupus vulgaris were cured under the administration of moderate energies after a small number of exposures, which had not lasted longer than five minutes. It is natural that under such circumstances the macroscopic evidence of inflammation did not show itself. Such cases also leave very little scar-formation—a factor which is not to be underestimated, when the face, for instance, is concerned.

In lupus erythematodes irradiation must be continued for greater length of time than in the case of lupus vulgaris.

Successful treatment of nævus vasculosus is also reported. In epithelioma of the lower eyelid and of the cheek I have also obtained a perfect result after a few exposures only. (See *Münchener medicin-*

ische Wochenschrift, No. 32.) In spite of this fact, however, I still continue to regard extensive removal the proper treatment. The Röntgen rays, however, should be considered in the after-treatment. From the observation of Heidenhain, that carcinoma-cells are found below the fascia, even in apparently light cases of carcinoma mammæ, we surgeons saw the necessity of removing the pectoralis major muscle, or at least its superficial stratum. In fact, no surgeon expects perfect recovery from the simple removal of carcinomatous portions, but always tries to extirpate as much of the surrounding tissue as surgical technic permits. It is only too well known that if the carcinoma cells have disseminated themselves so far that they are not accessible to the scalpel, a speedy relapse is to be expected. Now, if we have a means, which would, after a thorough operation, penetrate the deeper strata, so that those carcinoma cells which were situated beyond the reach of the knife would still be attacked by it, and perhaps destroyed, or at least arrested in further development, the question of the therapy of cancer would be solved.

If the parasitic nature of carcinoma should some day be proved, the effect of an antiparasitic medium, like the Röntgen rays, could be easily understood. That the Röntgen rays possess antiparasitic properties will be shown below. But on the theory that carcinoma is an atypical proliferation of epithelial cells, independent of any bacterial influence, we can also conceive that the Röntgen light counteracts the proliferation.

Recently I have also tried to treat sarcoma with the Röntgen light. (See on a case of sarcoma treated by the Röntgen rays, *New York Medical Journal*, November 16, 1901.) While in the case reported the disease had reached a stage in which recovery could not be expected, the healing influence of the rays on the sarcomatous area was very marked.

Further experiments, of course, have to define the indications for the treatment of carcinoma as well as of integumental sarcoma.

In regard to the technic of irradiation for therapeutic purposes careful individualization is the condition *sine qua non*. The proverb: "Trying is better than studying," holds good in this connection too. At first it is best to expose for a short time and in long intervals, until the individuality of the patient is well studied. Some patients react soon, some after many exposures, and some do not react at all. It should be regarded an iron-clad rule to stop the exposures as soon as the patient feels a burning sensation in the irradiated area. Only after symptoms of this kind have again disappeared entirely, the irradiations may be repeated.

For the first time it is best to expose five minutes only. A week should elapse then before a second exposure is made. If after the third exposure, made two weeks later than the first, no inflammatory signs have shown, the patient does not seem to have an unfavorable idiosyncrasy, longer exposures and shorter intervals can be attempted.

The exposures may then last ten, twenty, or even forty-five minutes, and may be repeated every other day, in obstinate cases even daily. The risk of burning the patient under such powerful treatment is not small. In the treatment of malignant disease, however, this should not bear great weight. If a strong effect is desired, strong means must naturally be chosen. For the treatment of most skin diseases, however, an exposure of five to ten minutes, repeated every third day, is sufficient.

The tube is placed as near the area to be irradiated as possible (as an average at a distance of about four inches).

As a rule, tubes of low vacuum (soft tubes) should be selected for therapeutic purposes. The abdominal skin of the animals irradiated by me with hard tubes showed little change, while the viscera were hyperæmic. This shows that the penetrating light of the hard tubes is absorbed by the integument to a small extent only, while the internal organs are more strongly affected. On the other hand, the peritoneum showed hardly any reaction, while the abdominal skin became inflamed, when a soft tube was chosen. Still, these conclusions have to be taken *cum grano salis.*

That the Röntgen rays possess bactericidal properties cannot be doubted any longer. The antibacterial effect of sunlight is an illustrative analogy. "Where the sunlight has no access, the physician will soon appear," is an old and significant Italian proverb. In harmony with this consideration, derived from the observation of the development of tuberculosis, is the fact that cultures of the tubercle bacillus die if exposed to sunlight for three hours. Regarding the great similarity between the effect of sunlight and the Röntgen rays, the bactericidal property of the latter was obviously apparent. And, in fact, staphylococcus, bacillus coli communis, and cholera vibrio die after being irradiated for one hour only. That tuberculosis is influenced by the rays can be well assumed, the action being of a bactericidal as well as of an inflammatory character. It is well to remember that in tuberculosis we are to consider not only the bacillus, but also that metamorphosis which we know as the tubercular nodule. Artificial hyperæmia, as we were taught by Rokitansky, also arrests development of tuberculosis. It is well worth while to investigate this most important question more closely.

It seems, furthermore, that various bacterial types show various reactions in proportion to the different qualities of their plasma. Schaudinn (Pflueger's *Archiv für die gesammte Physiologie*, 1899, Bd. 77), for instance, found that among the protozoa labyrinthula macrocystis, Cientk showed no changes at all. The plasma of these types is viscid and inert. It is also indifferent against all kinds of irritation, while the lively amœba princeps Ehrbg., the liquid plasma of which contains large quantities of water, shows considerable change and dies, after being irradiated for ten hours. All kinds of infusoria perished after being irradiated for six hours.

In summing up, we may feel justified in expecting from the future many more valuable hints for the rational therapy of bacterial diseases.

In regard to precautions, it may be said that the healthy skin surfaces should be protected by tinfoil or lead plates during the process of irradiation for therapeutic purposes; for the face, masks made of lead are handy.

The patient who is advised to be treated by the Röntgen light must be informed of the risks of burning.

The treatment of the inflammation caused by the Röntgen light is virtually the same as that of ordinary burns quoted above. In simple dermatosis (burn of the first degree), applications of Burow's solution are most comfortable for the patient. For the bullous form (second degree) a xeroform gauze-dressing, after the blisters are opened and removed, is indicated for the first few days. Later on, I recommend a dressing of a 10-per-cent. xeroform-lanolin ointment, which is changed daily, provided there is but scant secretion. The necrotic form (third degree) requires speedy removal of the mortified tissues, the after-treatment being conducted after the principles of wound treatment. (Xeroforms or solution gauze, the latter to be preferred if there is much secretion. Torpid granulations are stimulated by an 8 per cent. solution of chloride of zinc.

During the intervals, xeroform salve should be employed prophylactically.

SUPRAPUBIC CYSTOTOMY IN OPERATIONS UPON THE PROSTATE.*

By HOWARD LILIENTHAL, M.D.
NEW YORK
ATTENDING SURGEON MT. SINAI HOSPITAL

"In the present state of our knowledge, hypertrophy of the prostate is not curable by any means that have yet been used." This statement will be found in the 1884 edition of Van Buren and Keyes.[1] By it we may understand that the unfortunate sufferer from an extremely common disease had to resign himself as best he could to a life of continued invalidism with the prospect of fatal complications staring him continually in the face. I will not here attempt the description of such a miserable existence. It is bad enough when a man advanced in years and feeble becomes thus a burden to himself, but when one considers how those in their prime, vigorous in mind and body, may be compelled all too soon to say of active useful life, "It is finished," and to give up the occupations and pleasures which they loved, it is small wonder that the spirit of rebellion is strong within them, and that no sacrifice is too great, no risk too hazardous, if it but holds out a promise of relief.

At a meeting of the Clinical Society of London, held in the year 1887, Sir Henry Thompson[2] reported a case in which, after repeated surgical procedures, he was gratified to present as a result of his endeavors a patient with a permanent suprapubic fistula. By means of a tube the leakage was controlled so that the man was fairly comfortable. Such instances are far from rare in surgical literature, and various devices have been contrived to render the fistula a tolerable burden. At the same meeting, and following Thompson's communication, McGill[3] reported three cases in which he had removed prostatic obstructions by the suprapubic route with the brilliant result that his patients were able to pass their urine in a normal manner. The accidental removal of obstructing portions of the prostate during the performance of perineal lithotomy had been occasionally reported with the information in a number of cases that there was considerable improvement in the condition. Länderer[4] after such a fortunate accident in which he took away a median lobe together with the stone for which he was operating, suggested that the procedure might well be more generally adopted. Belfield, Gouley, and other surgeons have with varying success removed obstructions by cutting them away with specially constructed scissors and forceps, and finally White and Harrison were responsible for the thorough testing of double orchidectomy and vasectomy.

Still, success with perfect function was the great exception, and the catheter had to be resorted to more or less in most instances. Finally, Fuller began the systematic enucleation of fibrous, myomatous, and adenomatous prostates in 1894[5] with excellent results, while the achievements of Alexander and others working through the perineum, and the revival of the Bottini operation of electrocaustic prostatotomy caused the entire subject to receive renewed attention. Yet, so late as last year, P. J. Freyer[6] in a paper on perineal prostatectomy shows a strange lack of confidence in the radical cure of senile enlargement of the prostate by remarking that "The vast majority of cases . . . are . . . best treated by careful, cleanly and judicious catheterism," an opinion which will hardly be shared by those who have seen the ideal results obtained with the aid of operative treatment.

I have performed the operation of suprapubic enucleation of the so-called hypertrophied prostate seven times with one death, one failure, and five complete cures. In addition, I have operated a number of times for other diseased conditions of the prostate, but these cases will not be considered here.

CASE I.—The first patient, R. L., upon whom I attempted to perform prostatectomy was a very corpulent man, sixty-six years of age, who had had suprapubic cystotomy done by me some months before because of acute retention with urinary sepsis. The enucleation was attempted on August 26, 1896. At the first operation he had taken the anæsthetic so miserably, owing to asthma from pronounced emphysema, that I resolved to do what I could with the help of eucaine injected into the vesical mucous membrane covering the prostate. There was so much straining, however, during the operation, and the abdominal walls were so enormously thick that I was obliged to desist after removing two adenomatous growths about as large as filberts. The man's condition was practically unimproved, and he now wears a glass tube which keeps him pretty dry during the day, but is forced to use thick gauze pads at night.

CASE II.—H. M., sixty-five years old, had been troubled for years with renal colic, and the symptoms of vesical calculus. Occasionally a small round stone, about the size of a pea, was passed by urethra. November 5, 1896, he was suffering from acute retention with genito-urinary sepsis following instrumentation. I operated on November 12, during the acute attack, the sepsis having proved intractable to the usual forms of treatment. Eighty-five small round stones were removed through a suprapubic vesical incision, and at the same time the enlarged and obstructing prostate was enucleated, a procedure which I believe should have been undertaken at a second sitting in this case. The urine could not be satisfactorily examined as to the condition of the kidneys, on account of the large amount of blood present, probably the result of the instrumentation. The operation was not a difficult one, but the patient died within twenty-four hours, his sepsis unchecked. No autopsy permitted.

The next case came four years after the one just reported.

CASE III.—I. L., seventy-four years old, but in excellent physical condition, except for his local disorder, had been afflicted with the burden of "catheter life" for twenty-two years, during which time not a drop of urine had been voided naturally. Several attacks of cystitis and epididymitis had threatened the patient's life with urinary sepsis, but had yielded to treatment. At the age of seventy, I had castrated him during an acute attack with some relief, but without any change in the obstructive condition. At last the exacerbations began to occur with greater frequency, and while he was convalescing from one of them, I performed suprapubic section with enucleation of the prostate and perineal drainage on September 25, 1900. A ball-valve median and two enlarged lateral lobes were easily shelled out. The combined mass weighed 41 grams. Hemorrhage was slight, and post-operative shock absent. Recovery was quick, complete, and apparently permanent, for the man remains absolutely well now, more than a year afterward. His stay in the hospital was twenty-three days. Although not strictly relevant, it is interesting to note that there were disagreeable nervous symptoms, apparently connected with the orchidectomy, such as sleeplessness and hot flushes, and that these phenomena promptly and entirely vanished on the internal administration of orchitic substance, and that the patient had not the remotest idea of the nature of the medicine he was taking.

---

*Read before the New York Surgical Society at its regular meeting, November 27, 1901.

CASE IV.—J. R., fifty-eight years old, had had two attacks of gonorrhœa when he was eighteen years of age, and an initial lesion with secondaries at twenty-eight. Until his fifty-third year his history is otherwise negative, but at that time he began to have increased frequency of micturition, noticed especially at night. He was first catheterized about the middle of May, 1901, when his physician noted that there was residual normal urine to the amount of seven ounces. Regular catheterization was instituted, and five weeks before I saw him there developed a severe cystitis, accompanied by left epididymitis. On July 3 I had Mr. R. admitted to Mount Sinai Hospital. At that time there was no fever, and pulse and respiration were normal. The urine contained a trace of albumin and considerable pus, in spite of the fact that he had been under the usual preparatory treatment for several days. On July 4 I operated, and on opening the bladder from above noted that there was a large prostatic mass projecting over the internal urethral orifice from above, and that the remainder of the gland was very much enlarged, as one would have been led to suppose from the rectal palpation. The anterior portion was first removed by enucleation, and then three other masses were taken away, and the operation concluded without perineal drainage. Hemorrhage was moderate and easily controlled. The subsequent course of the case was uneventful and the patient was discharged from the hospital well, except for a granulating suprapubic wound which has since closed. The recovery is perfect, and the functions of micturition and coition apparently normal.

CASE V.—M. G., fifty-eight years old, had suffered for two years with frequent micturition and finally with retention and overflow. On May 26, 1901, when he first came under my observation, there was marked cystitis with fever. Catheterization with the rubber instrument was impossible, but a woven Mercier passed a distinct obstruction at the neck of the bladder with comparative ease. The prostate was felt to be enlarged, on examination with the finger in the rectum; but the complete retention led me to suppose that we had to deal with a middle lobe. Operation was proposed and accepted. After two days of preparation with frequent catheterization and diuresis, the suprapubic section was done at Mt. Sinai Hospital. There was still considerable urinary sepsis, the temperature rising as high as 102°. Thirty-six ounces of urine were passed on May 27, the day before the operation, and there was but 1.2 per cent. urea, the specific gravity being 1.010. There was a trace of albumin, accounted for by the presence of pus; but there were no casts. At the operation the bladder wall was found considerably hypertrophied, and there was a large sacculation in its upper right portion. A middle lobe, the size of a marble, pedunculate, and acting as a ball valve, was easily enucleated. The remainder of the prostate, though somewhat enlarged, was fibromyomatous in character, and could not be enucleated. I assured myself that the obstruction had been perfectly relieved by passing a very soft rubber catheter into the bladder through the urethra, and concluded the operation without perineal drainage. There was practically no reaction, and convalescence was ideal. The patient was discharged on July 8, passing all the urine in his bladder at each micturition, and apparently well. Since his discharge from the hospital, he has enjoyed sexual congress in an apparently normal manner.

CASE VI.—J. R., sixty years old, entered Mt. Sinai Hospital in June, 1900, with a characteristic history of senile prostatic enlargement dating back a number of years. The immediate cause of his seeking admission was severe hæmaturia, with great vesical distress. The patient was quite feeble, and suprapubic cystotomy for drainage seemed to be all that he would safely stand in the way of operative therapy. Dr. Brewer, at that time adjunct surgeon, operated for me, and found that in addition to a considerable prostatic enlargement, which could be felt by rectum, there was a distinct pedunculated middle lobe which he was tempted to remove. On account of my suggestion that drainage would probably be all that the patient would safely endure, the operation was completed by the insertion of a tube, and the man was sent back to bed, where continuous vesical siphonage was instituted. Recovery with very great improvement followed and in a few weeks, the suprapubic sinus having closed, the patient was taught to catheterize himself and was discharged. He re-entered the hospital on May 16, 1901, suffering with dangerous bleeding from the urethra after an attempt at catheterization. Besides the occasional reopening of the suprapubic fistula, the patient, with frequent catheterization, had been quite comfortable until the hemorrhage, which had begun five days before his readmission, and had continued the entire time with varying severity. There was no fever. The urine was so bloody that it could not be properly examined. Cystitis, if present, was not severe. A soft-rubber catheter could not be passed, but a silk Mercier entered the bladder apparently through a false passage in the floor of the urethra. Some urine came through the suprapubic opening. Under the influence of urotropin and frequent catheterization, together with the injection of nitrate of silver solution, 1-750, the hemorrhage ceased, excepting on attempts at voluntary micturition, when the urine was always of a bright red color. On May 25, nine days after admission, I operated, employing nitrous oxide and ether anæsthesia. The old scar with the sinus was excised, and the peritoneum wounded during the procedure. The opening was closed by continuous suture, and a piece of gauze laid over the line of union further to protect the abdominal cavity. The prostate was enucleated in three masses weighing in all 66 grams, and the cavity packed with gauze to control the bleeding, which was considerable. No perineal opening was made. Convalescence was rather slow, after the first shock of the operation, on account of the formation of a dense tumor to the right of the bladder, evidently a pelvic exudate. The mass was aspirated through an incision, but with a negative result. Urine was voided through the urethra on June 10, and the patient was discharged, emptying his bladder and passing all urine by the natural channel, on August 17. He is now well, and when I last examined him, there was no residual urine. He gets up once at night, and passes water every four hours during the day.

CASE VII.—J. H. C. was referred to me on June 23, 1901, because of impediment to urination and severe bleeding from the urethra on attempted catheterization. He was fifty-six years old, and, with the exception of a gonorrhœa in his youth, had been in robust health until three years before, when an attack of retention had been relieved by the use of the catheter. For two years he had remained apparently well except for some frequency in micturition. Then another attack of retention occurred, and the catheter had to be once more resorted to. After that the attacks became more and more frequent, and about three months before he came to me, there was severe bleeding after the use of the instrument. Following that any attempt at catheterization or other manipulation about the urethra occasioned hemorrhage, which was described by the patient as extremely severe. Some residual urine was invariably present after he had voided all he could. I found the general condition very good, excepting that the loss of blood had resulted in a fairly marked anæmia. With the greatest gentleness I attempted to pass a woven olive-tipped catheter, but on reaching the compressor urethræ a hemorrhage began which was the most alarming in my experience. A steady, fast stream of arterial blood came from the meatus, as if from a wound in a large vessel, and I was glad to be able to check the flow by compression of the urethra. The prostate by rectum felt large and hard.

The patient was advised to enter the hospital so that an operation through the perineum might be performed for the purpose of checking the tendency to hemorrhage. He was admitted as a private patient on June 25, and the following day the operation was undertaken. The curved von Dittel incision, as for the evacuation of a prostatic abscess, was made, and the deep urethra thoroughly exposed. On opening the canal, a severe hemorrhage at once occurred, and it became evident that there was a false passage directly into the bulb. This region was packed, and the bleeding having ceased, the urethral incision was continued backward into the prostatic portion, it being my intention to explore the bladder with the finger. The prostate was, however, so large, and the urethra was so much lengthened by the hypertrophy, that my finger would not reach the vesical cavity. Suprapubic section was made, and the prostate enucleated with little difficulty in three large fibrous lobes weighing together 126 grams. Drainage by tubes in the perineum and in the suprapubic wound completed the operation. Within the following twenty-four hours there was considerable bleeding, so that the bladder and perineal wounds had to be packed again. A bronchopneumonia with delirium made me very uneasy for several days, but by the middle of the second week convalescence was safely established. A suppurative epididymitis developed on the sixteenth day, and an incision was necessary a few days afterward. By the twenty-fourth day all the urine was voided through the normal channel, the suprapubic vesical opening having closed. One month after operation the patient was discharged, a granulating wound of the scrotum still present, but otherwise well. The urine was not yet perfectly clear, but there was perfect function as to micturition, not a drop of residual urine remaining. He is at present in excellent health, and his urine is normal.

Each one of the last five cases was reported on by Dr. F. S. Mandlebaum, pathologist to Mount Sinai Hospital. Every specimen was cut, stained, and microscopically examined. The report states that in all there were evidences of an increase in all the elements of the prostate, gland, fibrous tissue, and muscle, forming the usual "hypertrophy" of the prostate. No pure adenomatous or fibromatous masses were found.

I have ventured to bring before you this evening these patients and histories, in order to demonstrate the value of the suprapubic vesical incision in removal of the prostate—a procedure which, for reasons unknown to me, has not attained the popularity which I feel it deserves. In speaking with my colleagues I find that it is the exception to meet one who has had experience with it. Then too, while I am willing to admit that this particular operation for the relief of the disease may not fit all cases equally well, I wish to urge that, as a general rule with few exceptions, the first step in the operative cure of any form of prostatic obstruction should be a suprapubic cystotomy, even if it should later become evident that the disease itself must be attacked from another quarter. It is the only way in which we can gain absolute certainty as to the condition of the bladder. Those who favor the perineal route may be successful in selected cases, but there must always be an element of doubt unless the interior of the bladder can be thoroughly seen or palpated. Naturally, it can never be properly examined by vision through the perineal opening, and often, especially in the presence of great enlargement of the prostate, the finger is not long enough to reach the vesical opening. The cystoscope, valuable as it is, has its limitations, and in any event cannot be compared in point of accuracy to direct observation through a wound in the bladder. In the presence of active hemorrhage the instrument is far from one of precision, and in certain forms of prostatic obstruction it cannot be introduced at all. Thus, ulcerations, neoplasms, diverticula, sacculations, incrustations, and even stones, especially those occupying pouches, may be overlooked, to the detriment of accurate prognosis and good surgery. Galvanocaustic prostatotomy is, undoubtedly, an important means of relief, and is eminently suitable in many cases; but it must be admitted that, unless this operation is preceded by suprapubic section, one must take the risk that serious intravesical trouble exists which may nullify the expected benefit. Besides, the cystotomy gives us the additional advantage of drainage in complicating cystitis. I have in mind a case of carcinoma of the prostate in which cystoscopy was impossible, because of hemorrhage, and in which the diagnosis of probable prostatic hypertrophy had been made. Suprapubic operation was undertaken for purposes of exploration as well as treatment, and the tumor thoroughly curetted. The result was cessation of hemorrhage, and great amelioration of the symptoms, the respite lasting for several months. The suprapubic wound healed quickly. This might not have been thought a fit case for galvano-cautery, in any event, but the perineal operation might have been considered with the probability that the bleeding would not have been checked, and that the wound, being in cancerous tissue, would never have closed.

In dealing with chronic obstruction at the neck of the bladder, the primary step, then, should be suprapubic section. After this, according to the condition of the bladder and the character of the obstruction, the operation may proceed. If the case is one of prostatic "hypertrophy," the second step should be selected according to the condition of the patient and the character of the obstructing mass. Small nodules obstructing the internal urethral orifice may be removed either through the incision already made or through an additional opening in the perineum which may be left for drainage. Moderately large masses which can probably be enucleated may be removed either from above or below, according to anatomical conditions, and the superior wound will then be found of great value because it permits an assistant to press directly upon the gland, forcing it within easier access from below. If the patient is very old or feeble or if he takes the anæsthetic badly, the operation of enucleation from above will usually be found much speedier than the perineal dissection. Should a very large prostate be encountered, it is not probable that it can be enucleated from below.

If the prostate is very soft and hyperæmic or if it is of such a texture that it cannot be enucleated, one has the choice of galvano-cauterization through the urethra (Bottini), through the perineal wound, or of removal with the cutting-forceps by conjoined manipulation.[7] In any case, the suprapubic wound will be of great service. Its disadvantages I believe to be greatly exaggerated. The operation of opening the bladder from above is quick, simple, and in my experience accompanied by little shock. The mere cystotomy is far less bloody than the usual perineal section. When speed is the all-important element, as it frequently is in old persons, it must be remembered that the cystotomy takes only a few moments. The entire operation with removal of the prostate is finished in from fifteen minutes to half an hour.

The steps of the operation as I have performed it are briefly as follows: Washing out the bladder, the catheter being left in the emptied viscus. Incision of the tissues through the linea alba. Retraction of the recti. Inflation of the bladder with air, using an ordinary atomizer bulb fixed to the catheter. Palpation of the parts through the wound, so as to judge of the size and shape of the bladder, as well as the degree of inflation. Pushing up the peritoneal reflection. Opening the bladder between two retracting sutures. Exploration of the viscus with the finger, then by the eye, raising the pelvis if necessary. Snipping the mucous membrane covering the most prominent portion of the prostate. Enucleaation of the gland with two fingers of the left hand, while an assistant with finger in the rectum supports the parts. A perineal opening may or may not be made, according to the exigencies of the case. I am of the opinion that when a capable nurse is to be in charge, the bladder and the laceration in its floor can be perfectly drained with the continuous siphon apparatus without the opening from below. If perineal drainage is decided upon, however, it is easy to cut down upon the beak of a sound placed within the space left by the removed prostate, and pushed against the tissues, so that it presents in the perineum.

In two of my operations I placed sutures of chromic catgut at either side of the drainage tube, inverting the bladder wall after the manner suggested by Gibson;[8] but, in all of my cases, time seemed an important element, and anything which tended to lengthen the operation was avoided.

All patients should be prepared by free purgation and diuresis. The latter is most important, and I attribute the fatal termination in Case II. very largely to the fact that this precaution could not be thoroughly carried out. The administration of urotropin and copious draughts of water seem to be perhaps the best way in which this can be accomplished, the urotropin acting as a urinary antiseptic as well. It is my habit to continue the administration of the water until within two hours of the time set for operation.

The principles of the scientific treatment of chronic prostatic obstruction are being steadily evolved. As with all diseases, so here; each individual case must be treated according to its needs, and the skill of the surgeon is not so much required in the carrying out of his plan as in its proper and careful selection and elaboration. My argument for suprapubic section is advanced with the hope of aiding the cause of thoroughness and accuracy.

ALCOHOLIC AMAUROSIS.*

By FRANK VAN FLEET, M.D.,
NEW YORK.

SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL, PROFESSOR OF DISEASES OF THE EYE AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, ETC.

In the Manhattan Eye and Ear Hospital Reports for 1897, I published the case of a man who became suddenly blind after drinking a large quantity of methyl alcohol. According to Dr. G. E. de Schweinitz of Philadelphia, this was the second recorded case; since then a number of similar cases have been recorded.[1] So far as I know there have been reported no cases of blindness following the use of ethyl or ordinary alcohol.

In all cases reported the inference has been that methyl or wood alcohol was the agent which produced the blindness, but there has been no positive proof that this was the real cause. As a rule, blindness has followed intoxication, and wood alcohol has been a factor in the production of the intoxication. In the case reported by De Schweinitz, blindness supervened on a sleep following the administration of morphine in a man who had been exposed for some time to the fumes of wood alcohol, and who suffered from symptoms identical with those described in textbooks as following the inhalation of the vapor of this kind of alcohol.[2] In this case the patient had not taken any of the substance internally, but was addicted to the use of alcoholic drinks; the report does not say to what extent. He had worked in white lead for five years, and he had also suffered from previous attacks of temporary obscuration of sight. Stierin reports the case of a man who had been drinking heavily, and who becoming sober in a place where he could not obtain his accustomed beverage, and feeling that he must have some sort of drink, took the only thing he could get hold of, which was what is known as Jamaica ginger, of which he drank twelve ounces. He fell into a deep stupor, from which he awoke blind, recovering, however, in a few days excellent vision. Stierin, in commenting on this, states he has found eight recorded cases of blindness following the ingestion of ginger.[3] It has been suggested that blindness following the ingestion of these strong alcoholic essences is due to the methyl alcohol contained in such preparations.

In the case I reported in 1897, a man addicted to the habit of periodic sprees, after exhausting his means of supplying himself with whiskey, resorted to a solution of red pepper in water. This not satisfying him, he drank a sufficient quantity of methyl alcohol to plunge him into a profound stupor, from which he awoke blind. After a temporary improvement, he finally lapsed into a condition of permanent blindness, with total atrophy of the optic nerves.

The case I desire to report now is that of an inmate of a place of detention for inebriates. This patient, a woman of refinement, had voluntarily secluded herself in this institution in the hope that she might rid herself of an appetite for alcoholics. For six months she was not out of the institution, and during this time took no alcoholics, drugs, or medicines of any kind. Feeling that she had overcome her appetite, and having some business to look after, she sought and obtained permission to leave the institution for a few hours. After transacting her business, the desire for a drink seized her, but she knew the people in the institution would detect the odor on her breath, and she fought off the desire as long as possible. Finally, she went to a drug store and bought a bottle of ordinary alcohol, and returning to the institution, pleaded fatigue and retired. Once in her room she locked the door and drank the alcohol. She soon sank into a deep sleep, which became a prolonged stupor lasting several hours, from which she awoke blind.

---

* Read before the Medical Society of Queens-Nassau.

The patient was transferred at once to a general hospital and was told her sight would return. I saw the patient eight weeks after the sudden loss of vision, and made the following note: Pupils dilated ad maximum, with no reaction to light. Vision in the right eye, ability to count fingers at two feet. Vision in the left eye, barely perception of light. Optic nerves, dead white, blood vessels, small.

I began at once the administration of sulphate of strychnine hypodermatically, commencing with $\frac{1}{60}$ of a grain once a day, increasing at the rate of $\frac{1}{160}$ of a grain each day, until the daily dose became $\frac{1}{4}$ of a grain. This seemed to be the point of tolerance in this case, and the dose was continued at $\frac{1}{4}$ of a grain daily for four weeks, after which the same quantity was given by the stomach daily, for a considerable period. At the end of six weeks' treatment, the vision in the right eye had increased to 20/200, and in the left eye to 3/200. The fields of vision were markedly restricted.

So far as I know, this is the only recorded case of acute retrobulbar neuritis following the ingestion of ethyl alcohol. In conversation with friends I have been told of other cases similar to this. There is no reason to doubt that such an event may not be infrequent.

Chronic or subacute retrobulbar neuritis in people addicted to the use of alcoholic beverages is not uncommon, and if we may expect a gradual or passive inflammation of the optic nerves from a gradual alcoholic poisoning, there is no reason why we should not have an acute inflammation following acute poisoning. There are, however, points of difference in the two conditions, *i. e.* the chronic and the acute forms.

Retrobulbar neuritis of the subacute or chronic variety, resulting from the use of alcohol or tobacco, is a gradual process, and manifests the most gratifying results with appropriate treatment. Acute retrobulbar neuritis, following the use of alcohol in toxic quantity, is sudden in its onset, and, as a rule, treatment accomplishes little or nothing. Let us consider these two conditions separately.

In people who are addicted to the use of alcohol or tobacco, or both, we sometimes have a gradual failing of vision, constituting what we term tobacco amblyopia, toxic amblyopia, amblyopia ex abusa, and so on.

This form of amblyopia results from a bilateral interstitial inflammation of the orbital portions of the optic nerves. The first symptom is failing vision. The person affected finds he cannot see as formerly, but the progress of the disease is so gradual that the patient may not be able to state when his vision began to fail. He is able to see better in a subdued light, and for that reason, Arlt has given to the condition the name of amblyopia nyctalopia.

Generally, when the patient consults a physician, the affection has been going on for some time, and the diminution of vision may be considerable.

An examination of the eye externally reveals little or nothing. If vision is markedly reduced, there will be the peculiar stare common to people who have poor vision. The pupils may be slightly dilated, and the reaction to light sluggish. The fields of vision are not restricted; indeed, peripheral vision may be better than central vision. There is an inability to distinguish red and green in the center of the visual field, constituting what is called a central scotoma for these colors. This is a symptom of value, which may be absent in the early stages of the affection.

The ophthalmoscope reveals nothing on which we can base a positive diagnosis, except that the optic papilla presents to one familiar with ophthalmoscopic pictures, an appearance which is suggestive. The nerve has a peculiar, dirty look, which—taken in connection with the diminished vision, the central scotoma for red, and the over-indulgence in alcoholics, or tobacco, or both—makes the diagnosis positive. I have seen patients who complained of a heavy feeling in the eyes, when the vision was slightly or not at all affected, and who presented no scotomata, but whose optic nerves had this peculiar appearance, become entirely relieved of their disagreeable symptoms by stopping the use of tobacco and taking strychnine.

The prognosis in this form of retrobulbar neuritis is good. Possibly, if patients refrained from any kind of treatment and persisted in the unrestricted use of alcoholics and tobacco, atrophy of the optic nerves would result; but I have never seen a case where this could be demonstrated. I have seen a great many cases of complete atrophy of the optic nerves in which there was no history of any disease capable of producing such a condition, and it is fair to suppose some of them may have been due to this cause. There are people in this world who would allow themselves to become almost blind before seeking medical advice; so it is possible a person afflicted with this form of retrobulbar neuritis might wait until the disease had reached this final stage before seeking relief. As a rule, however, when the vision has become reduced to a point when it is no longer sufficient for the ordinary uses to which vision is put, the person seeks medical advice. If vision is not reduced below 20/70, and the central scotoma is only for red and green, removing the cause and placing the patient under the influence of strychnine will be sufficient to effect a cure.

The central scotoma or blindness for red and green is not a permanent condition unless it is allowed to run its natural course, in which case it becomes a complete blind spot. This result is due to atrophy of the papillomacular bundle of the fibers of the optic nerve, and, as we all know, there is no power of which we have knowledge which can restore an atrophied nerve.

In acute retrobulbar neuritis we have a different condition of affairs. This acute disease is said to have resulted in some cases from great chilling of the body, and from excessive physical exertion.[1]

Most of the reported cases have followed the ingestion of alcoholic preparations, or of pure alcohol, in quantities sufficient to produce intense constitutional disturbance. I have never heard of a case following the drinking of the ordinary forms of alcoholic stimulants; the cause has generally been the ingestion of either pure alcohol, or of strong alcoholic preparations. The essences of various kinds, as essence of anise, essence of peppermint, essence of ginger, etc., contain from 80 per cent upward of pure alcohol, and supposedly the ethyl or common alcohol. De Schweinitz suggests that some of these essences now in the market may contain methyl or wood alcohol or, as it is sometimes called, Columbian spirit. In conversation with druggists, I find it is commonly believed that wood alcohol is often substituted for ethyl alcohol because the former is cheaper. In Great Britain, methyl alcohol, not being fit for internal administration or for drinking purposes, is not subject to taxation, whereas ethyl alcohol is taxed. In order to obtain ethyl alcohol for use in the arts at a reduced cost, a mixture of nine parts ethyl alcohol with one part methyl alcohol is made, and this, not being fit for internal administration, escapes taxation.[2]

There must be a strong temptation on the part of unscrupulous manufacturers to substitute the cheaper alcohol for ethyl alcohol, and while the case I record shows that the same results may follow the use of ethyl alcohol, the fact that such cases have not been recorded must demonstrate that they are not so apt to follow the use of this form of alcohol.

The constitutional effects of all forms of alcohol seem to be the same, except that those produced by ethyl alcohol seem, as a rule, to be much milder. The addition of amylic alcohol, or fusel oil, to alcoholic drinks, causes more rapid intoxication. In large doses, fusel oil produces insensibility, or a profound and death-like sleep.[6]

Wood alcohol and ethyl alcohol produce the same results as amylic alcohol in this respect, but in the cases of poisoning from amylic alcohol reported by Dr. Fucher of Baltimore[7] no mention is made of the optic nerves being affected in any way. However, it may happen in many cases that intoxication from methyl or wood alcohol produces no trouble with the optic nerves, and there may yet be cases reported of blindness following the use of amylic alcohol. It is reasonable to suppose, as the constitutional symptoms produced by the ingestion of all forms of alcohol are the same, that they all may be capable of producing the same effect on the optic nerves.

It is, of course, possible that the blindness following the use of common alcohol in the case I have reported may have been due to contamination, or adulteration with wood alcohol, and that there may be something in wood alcohol which makes it especially dangerous to the eyes.

The condition presented in all cases of blindness following the ingestion of wood alcohol has been about the same. After taking a sufficient quantity to produce profound stupor, the victim has awakened blind. The pupils are widely dilated and do not respond to light; there is no perception to light, the patient being unable to distinguish between light and darkness. The ophthalmoscope reveals in the beginning little or no change in the interior of the eye. The nerves may be slightly reddened, and there may be engorgement of the retinal veins, with a diminution of the size of the arteries. These appearances are often seen when there is nothing the matter with the eyes at all. In the case of blindness following wood alcohol poisoning, which I reported, and which I observed from the beginning, there was at first nothing to be seen in the eye ground which could be said to be abnormal, but gradually the nerves became whiter and whiter, until complete atrophy was present.

The poison produces an interstitial inflammation of the optic nerves sufficiently severe to prevent retinal impressions being carried to the brain. If this inflammation is sufficiently intense, atrophy supervenes and the blindness is permanent. No cases of papillitis from this cause have been reported, hence the disease is called retrobulbar neuritis with descending atrophy.

The affection in some cases has been transitory, the patient recovering with good sight; but in others, although there has been temporary improvement, total and permanent blindness has resulted. The result must depend on the intensity of the inflammation; if it is sufficient to produce atrophy, blindness, or at least impaired vision, must result The prognosis must therefore be guarded until the acute stage is passed and vision begins to return, or atrophic appearances present themselves. The derivative treatment seems to have given the best results. This consists of free catharsis from jalap, calomel, and salines, with diaphoresis from hypodermics of pilocarpin. The beneficial results from this treatment must be obtained, if obtained at all, in the first few days of the acute inflammatory stage. If positive beneficial results do not follow in a week, atrophy is likely to result. When atrophy begins to show itself, the orthodox treatment will be strychnine, given hypodermatically in increasing doses. A solution of the sulphate is generally employed of the strength of 1 in 60, and the patient is given one minim, which represents $\frac{1}{60}$ of a grain of the drug. The next day two minims are given; the third day three minims, and so on, increasing by one minim a day until the point of tolerance is reached, at which dose it must be continued for at least a month. The patient must be watched for half an hour after each injection so that dangerous symptoms of strychnine poisoning may be checked.

When this form of treatment was first advised, it was recommended that the forehead or the temporal region be the place selected for the injection. I prefer to give them in the arm, and I also prefer starting with a smaller dose. A solution of strychnine, 1 in 120, is better, I think, which enables you to increase at the rate of $\frac{1}{120}$ of a grain daily, enabling you to watch its effects better, and enabling the patient to tolerate a larger dose in the end.

The point of tolerance in most cases when the patient is robust will be from $\frac{1}{6}$ of a grain upward. I have given as much as $\frac{2}{3}$ of a grain of the sulphate of strychnine twice a day hypodermatically in optic-nerve atrophy, producing marked constitutional effects, without influencing, I am sorry to say, the atrophy.

The prognosis when atrophy begins to show itself is very bad, the most you can hope to do under these circumstances is to check the atrophic change, which we are seldom able to do. As a rule, the affection goes on until complete blindness results.

Cases of this class demonstrate to the physician two plain duties. First, to point out to the public the fact that wood alcohol is a positively dangerous substance to take internally, and which may even produce permanent blindness if the fumes are inhaled for a long time. Possibly other forms of alcohol may produce the same results if concentrated. Second, to point out to health authorities the fact, if it is a fact, that the cupidity and avarice of certain unscrupulous manufacturers and dealers in alcohol and alcoholic preparations may lead them to substitute methyl alcohol for the ordinary alcohol of commerce, because the former is cheaper, and that this substitution may work injury to consumers.

The World's Centenarians.—"It is not surprising," says an English weekly journal, "that more people live to be 100 years old in warm climates than in the higher latitudes. The German Empire, with 55,000,000 inhabitants, has 778 centenarians; France, with 40,000,000, has 218; England has only 146, and Scotland 46; Sweden has 10; Norway, 23; Belgium, 5; Denmark, 2; Spain, 401, and Switzerland none. Servia, with a population of 2,250,000, has 575 people over 100 years old. It is claimed that the oldest living person, one Bruno Cotrim, living in Rio de Janeiro, is 150 years old."

REPORT OF A CASE OF ADDISON'S DISEASE.

By [illegible] A.M., M.D.

[illegible]

Inasmuch as cases of Addison's disease are so rare in this country, it has occurred to me that members of the profession might be interested in a report of a case which I had the privilege of seeing some time ago. I regret that the notes of the case are so meager, but as there were but three days in which the patient was seen before death it was impossible to secure a full report.

On May 29 I was consulted by a lady with regard to her health. She was of slender build, small stature, about forty years of age. She complained of repeated attacks of gastric trouble with vomiting and said that she thought she was in a bilious condition because her skin had become so yellow, in fact almost brown. I noticed that there was no discoloration of the conjunctiva and therefore concluded that there was no jaundice. In fact the conjunctiva had a peculiar pearly hue which I believe has been stated by some authorities to be frequently seen in persons suffering with this disease. Attempting to make an examination of her abdomen in order to ascertain the condition of the abdominal organs I found its walls very tense and hard, the intestines being so filled with gas, and the whole abdomen so tympanitic that it was impossible to outline the abdominal organs. I accordingly prescribed for her a carminative preparation, intending to get rid of the gas before attempting to outline the internal organs or ascertain her exact condition. I also requested a specimen of urine for examination. She was going out of town for a week or more and I expected to lose sight of her for the time being. I was much surprised, therefore, at having a visit from her on the evening of June 2, just four days later, when she told me that she had felt so bad while she was away and her stomach had troubled her so much that she had decided to return home. She complained that evening of extreme sick stomach, and the abdomen was still much distended with gas. I again prescribed for her, giving her some remedies to correct her sick stomach. On the morning of June 4 I was called to see her at her house and found her vomiting continuously and complaining of considerable pain in the abdomen. This continued throughout the day with marked failure of strength and increased rapidity of pulse, and all efforts to settle the stomach were entirely unavailing. Every attempt to give food or medicine resulted in the rejection of each dose as rapidly as taken. I might say here that by this time I suspected that the patient was suffering with Addison's disease, but could not fully convince myself of it because of the great rarity of this affection. On the night of June 4 the lady's husband greatly surprised me by asking me this question, "What is this Addison's disease?" I replied that it was my opinion that she was afflicted with that disease. I inquired how he had heard of this disease and whether any physician had ever told him that his wife was suffering with it. He replied that no physician had ever stated that his wife was suffering with "Addison's disease," but that her skin had been so much discolored that on looking up pigmentation of the skin in an encyclopædia he had found a description of "Addison's disease" and had suspected that this was the trouble with his wife. The following morning, June 5, I called upon my patient early in the morning and found her rapidly sinking. She died some time before noon.

Fortunately the family consented to an autopsy being made, and with the assistance of Drs. Kotz and Dudley the body was examined. I will not now take up space with a detailed description of the post-mortem appearances, but will merely say that the abdominal organs were practically in a normal condition. The stomach was somewhat congested and irritated, as it of course would have been from the patient's repeated attacks of gastric trouble and vomiting. The suprarenal bodies, however, were much wasted (not more than one-third or one-half the size of these organs in health). No marked lesion of the sympathetic nervous system was discoverable. The mesenteric and lymphatic glands were apparently healthy. My own opportunities for studying this patient were so few that it was impossible for me to gain an accurate knowledge of her personal history or the course of the disease. On account of the rarity of the disease it surprised me to have a case occur in my own practice. I had previously seen two cases during my course of study at the Medical Department of the University of Pennsylvania. They were both in men and singularly too, both were hunters from the Allegheny Mountains.

My patient's husband has given me the following outline of her personal and family history. I found that she had rarely been ill during her life except with various forms of gastric trouble. She was born on a farm of about sixty acres and during her early years had to do a great deal of the work of a hired man, such work, at least, as a girl can do, so at that time her life was quite an active one. After she became of age she attended school for several terms. She married at the age of twenty-five and during the first five years her life was an active one, but after that she became more engaged in writing for her husband, who was a professional stenographer, and consequently she led a rather inactive life. For some years after her marriage, especially at a time of mental strain, she was troubled with severe bilious attacks (as the family called them) with vomiting of bile, and at these times would be quite prostrated. After five or six years this passed away and she thought her general health much improved. She always had a dark complexion, and was always inclined to be sallow. Her husband stated that he was particularly impressed with the marked sallowness of her skin during the month of January previous to her death. For a year or more before her death she failed in strength, and, in fact, during this period of time it was noticed that the heat of the summer seemed to oppress her very much more than ordinarily. It was impossible for me to ascertain the exact length of time during which she had a return of the so-called bilious attacks, as these had been so numerous in the years of her married life that it was easy to see that the return of them would not excite any great surprise.

Family History. Her parents are still living. Her paternal grandfather died young from habits of intoxication, the paternal grandmother is said to have been a very strong and vigorous woman (though small in stature), who, almost unaided, raised a large family, none of those, however, developed very robust health. The maternal grandfather was a man of vigorous constitution and apparently lived to a good age. Of his children, however, only one seemed to be possessed of much stamina. Two or three of his children died of consumption. Of the patient's own family, one brother and two sisters are still living, one sister died at the age of twelve, another died three or four years before my own patient, leaving one son who seems to be quite healthy. This sister, I was told, had died of a malady similar to that of my own patient. I was never able to corroborate this statement, although one or two members of her family told me that their ailments were certainly very similar. Her sister died at the age of about thirty.

As before stated, my own opportunities for studying this case were so few that it is impossible for me to give a full and accurate history of the course of the disease. It may not be uninteresting, therefore, for me to quote Addison's own words: "The leading and characteristic features of the morbid state to which I would direct attention are, anæmia, general languor, and debility, remarkable feebleness of the heart's action, irritability of the stomach, and a peculiar change in color in the skin, occurring in connection with a diseased condition of the suprarenal capsules." I think no better definition than this could be given now, though it is many years since Addison wrote these words. The disease is more frequent in males than in females. According to Dr. Greenhow's inquiries, the relative proportion is 119 males to 64 females. The majority of the cases occur between the twentieth and fortieth year. As a good example of how infrequently the disease occurs, and how rare it is in America, it may be stated that Dr. William Osler, writing in 1892, states that but eight cases had come under his personal observation, either clinically or anatomically.

With regard to the pathology of the adrenals, it may be said that their most common affection is: (1) Tuberculosis. There may also be (2) Atrophy of one or both glands due to an interstitial cirrhosis. In the case reported above there was atrophy of both glands, which had also undergone a hyaline degeneration, with almost entire destruction of the stroma; (3) There may be malignant disease of these organs, although this is not a very common condition; (4) The condition of the abdominal sympathetic nervous system may be disturbed. "The nerve cells of the semilunar ganglia have been described as degenerated and deeply pigmented, and the nerves sclerotic. The ganglia are not uncommonly entangled in the cicatricial tissue about the adrenals." As to the causation of this disease, several theories have been advanced: (1) That the disease depends upon the loss of function of the suprarenal capsules. This was the view of Addison himself. It was supposed that the blood became poisoned by the retention in the system of some material, the destruction or alteration of which was the peculiar function of the suprarenal capsules; (2) That it is an affection of the sympathetic nervous system most frequently produced by disease of the suprarenal capsules, but also by other chronic affections, involving the solar plexus and its ganglia. According to this view, the disease is really one of the nervous system, and the pigmentation is caused by changes induced through the trophic nerves. Dr. Osler states, with regard to this last theory, that "opposed to it are the facts that the lesions described in the sympathetic system are indefinite, and identical changes occur without the symptoms of Addison's disease."

With regard to the duration of the disease, no definite course has been observed. Inasmuch as the early symptoms are uncertain, it is usually impossible clearly to define the onset of the disease. It has been stated by some authors that there are acute and chronic varieties of the disorder. Most cases are said to end fatally in the course of a year or eighteen months, others have been known to last for some time.

Malaria Following Abdominal Operations.—I. T. Freeland reports two cases which prove that there are exceptions to the rule that post-operative fever means sepsis. One case was operation for appendicitis, the other a myomectomy. After both, the temperature rose to over 102°, without traceable cause. Finally, recollecting that in malarious districts, laparotomies are apt to be followed by malarial fever, quinine was given, with very rapid fall of temperature as a result, and excellent recovery.—*Indiana Medical Journal.*

Myositis Fibrosa.—Montgomery H. Biggs reports a typical case of this comparatively rare affection. The site of predilection may be said to be the lower extremity, the muscles of the thigh and leg being attacked with equal frequency. There is seldom any febrile reaction and little if any general constitutional disturbance. Spontaneous pain may be intense. Upon palpation one finds an immovable firm tumor of woody hardness, the overlying skin is leathery, cannot be picked up in folds, and is of a deep brown color. The symptomatology of the secondary form is of more widespread distribution, and is ushered in by a process essentially acute. The diagnosis of both primary and secondary forms is difficult, and in many instances can be made only by a histologic examination of the affected tissue. The conditions with which it is liable to be confused are neoplasms, especially osteosarcoma, chronic osteomyelitis, and osteoperiostitis, and other forms of polymyositis, especially the syphilitic. In spite of the long duration of this affection, the prognosis is usually favorable; operative interference is indicated only when the mass causes sufficient pressure on adjacent nerve trunks to account for sensory or motor disturbances. Internal medication is practically of no avail. Massage and electricity, together with the use of variously medicated baths, seem to promote the absorption of a part at least of the fibrous tissue, and to give the best results.—*University of Pennsylvania Medical Bulletin.*

The Difficulties in the Treatment of Infantile Scorbutus.—E. W. Saunders considers the following complications: (1) *The infant has complete anorexia and refuses all food.* Forcible feeding must be resorted to; the food must be given in small quantities with a spoon, or better still, with a dropper. It may have to be introduced to the stomach tube; (2) *The infant vomits incessantly.* Several tablespoonfuls of orange juice in three or four ounces of starch solution or some cereal decoction should be given per rectum high up in the sigmoid twice a day; the irritability of the stomach must be quieted by appropriate means. Egg-albumin water is one of the best foods. When the stomach is improved in condition, meat juice, whey, and cream mixtures, or better still, human milk, is given; (3) *The infant suffers from enterocolitis.* Intestines must be cleansed by rectal irrigation; serous stools controlled by atropine and morphine. Some cereal decoction should be used as the base of foods; to this is added a little white of an egg, whey, human milk, or meat juice, but fruit juice must be added to whatever is used. Water with a little lemon juice should be given. Peach juice and grape juice can be given.—*St. Louis Courier of Medicine.*

What You Can Learn by the Study of the Urine Without a Microscope.—D. N. Kinsman says that the daily amount of urine should be measured many times in important cases. The daily amount in a healthy adult varies from forty to seventy ounces. It may be increased by refrigerative fluids, early stages of contracting kidney, polyuria, hysteria, diabetes mellitus, amyloid kidney, alcoholic drinks, critical discharges, and irritant poisons. Decreased, in cardiac weakness, last stage of contracting kidney, parenchymatous disease of kidney, choleraic diseases, and all diseases in which there are colliquative sweats. Color, odor, specific gravity, all indicate certain conditions. The amount of urea is of importance in certain diseases, and uric acid, creatin, and creatinin possess interest. Ethereal sulphates indicate proteid putrefaction, the other sulphates run parallel with the urea. Hæmaturia is significant, and albuminuria indicates a variety of conditions according to its amount, time, and manner of appearance, etc. Glucose may be temporarily present from the ingestion of certain articles of diet, from whooping-cough, or from some injuries to the brain. It is permanently present in diabetes mellitus.—*The Columbus Medical Journal.*

THE REGULATION OF THE PRACTICE OF HYPNOTISM.

EVER since hypnotism has been studied from a scientific viewpoint and placed in the rank of a rational therapeutic means, the principle, "Hypnotism for none but physicians," has been established by the consensus of authority.

In most European countries, where, as we well know, so much arrant quackery flourishes side by side with the strictest medical laws, it is unlawful for any person who is not a licensed physician to practise hypnotism as a means of treatment, or for any other purpose. In Russia—a country which we have long considered barbaric and semi-Oriental, but which in legislation against charlatanism probably leads the world—the regulations on this subject are most stringent. Not only must the hypnotizer be a physician, but a hypnotic seance cannot be held except in the presence of other physicians—a rule which, by the way, applies in Russia to all operations. In order to surround the patient with further safeguards, the hypnotizer must notify "the local administrative authorities"—in other words, the police—of his intention to hypnotize a patient, giving the date, hour, and the names of the medical witnesses. Public performances of hypnotism are absolutely prohibited, except in clinics or hospitals where only physicians and students of medicine are admitted. Public medical institutions are also exempt from the requirements of notification, simply because their officers are always directly responsible to the government. A careful press censorship is, in addition, exercised in Russia over all works on hypnotism accessible to the lay public.

Of course, the Russian regulations are incompatible with our ideas of personal and professional liberty, but it must be admitted that they express nothing but the legitimate solicitude of the government for the victims of ignorant and unscrupulous hypnotizers. In practice, we fancy that the enforcement of the requirements of notification reacts rather unpleasantly on the physicians themselves. Imagine a patient's thoughts, when he hears that, in order to obtain permission to treat him, the doctor must apply to the police! There is no doubt that the prejudice against hypnotism, which is unfortunately by no means confined to the uncultured classes, is immeasurably increased by such regulations.

We shall not attempt to discuss here the question as to whether hypnotization at the hands of physicians may produce injurious effects upon the patient. In general, it may be said, however, that restrictions placed upon physicians which set difficulties in the way of using any mode of treatment whatever are wrong in principle and hurtful in practice, except, of course, laws that concern acts criminal in intent. Yet in so enlightened a country as France, we are told by Grossmann in the *Zeitschrift für Hypnotismus*, the use of hypnotism as a therapeutic measure is prohibited in the military and naval hospitals. The source of such legislation is probably to be looked for in the prejudice of the authorities at the head of the medical departments of the French army and navy. Speaking of prejudice against hypnotism among physicians, it may be remembered that Virchow himself, on one occasion thundered against the "hypnotic leanings" of a certain class of German physicians. On the other hand, such authorities as Bernheim, Liébault, Forel, Krafft-Ebing, Schrenck-Notzing, Moll, Pierre Janet, and Danilevsky are unanimously in favor of unrestricted practice of hypnotism by physicians.

When it comes to the quack hypnotist and to the amateur mesmerist of the drawing-room, we are entering upon quite a different phase of the subject. In addition to the medical or scientific aspect, there are several questions in connection with this theme that should receive attention from our legislators. The first of these is the opportunity which the hypnotic seance gives for criminal acts, the second the possibility of inducing the "medium" to commit crimes under the influence of post-hypnotic suggestion. The effects of public performances, lectures, and "popular" literature on hypnotism upon the community is accurately expressed in the words of the circular of the Medical Department of the Russian Empire, as quoted in a recent article by Rosenbach in *Vratch*, 1901, 34, 1030: "Public performances of hypnotism may give unscrupulous persons the opportunity of learning the method of hypnotizing, and may enable them to employ this knowledge for immoral or criminal purposes; and, in general, hypnotic performances, without the appropriate scientific explanations, may breed wrong conceptions and create prejudices in the public mind, while post-hypnotic suggestions may be the cause of violations of the public order and peace, or of criminal acts on the part of the hypnotized persons."

In this country, unfortunately, the quack hypnotist, mesmerist, magnetist, or whatever he may call himself, is free to practise his "art" almost everywhere. The truth is, we have not yet, as a people, come to the realization that all freakish, sectarian, and mystic forms of quackery, whether profanely allied to religion or not, should be weeded root and branch out of our national existence. The lay mind is, and ever will be, so blinded by the brazen effrontery, the sleek and suave manner, and the irrational doctrine of the quack that it tolerates him, and alas! in how many instances greets him as the last resort. The result is that "hypnotists" who have been made in a few hours by paying the modest fee of five dollars to one of the numerous "institutes of hypnotism" that advertise broadcast in our best magazines, prey upon the public's credulity, endangering the health and the pocket-books of new victims day by day.

Let us hope that the time may come when physicians will assert their influence in the community in a less timid manner than they do now, and will secure the passage of laws against quackery in all its forms. In the meanwhile, the medical societies should take the regulation of the practice of hypnotism under consideration, and should begin a movement which will arouse the apathy of the public and of the profession to the abatement of the quack hypnotist

FILTH AND DISEASE.

Popular Science Monthly, January, contains an article on the above subject by Dr. Charles V. Chapin, which is a fairly good exposition of the views that largely prevail now, with regard to the connection between filth and disease.

Dr. Chapin takes the ground that the filth theory of disease, which has so long dominated medical thought, and has been accepted with trusting faith by all classes of the community, is absolutely dead, and forever discredited.

The writer claims that the germ theory of disease has shown that the deductions drawn by believers in filth as a cause of disease have been entirely erroneous and misleading, and further asserts that the germs themselves are rarely air-borne.

Cholera, typhoid fever, diphtheria, and bubonic plague are among others instanced as diseases, which knowledge, gained during the past twenty or thirty years, has proved to be due to a germ origin, and not, as was formerly held, to filth.

It has certainly been definitely decided that all these maladies are caused by bacilli; but on the other hand, no conclusive proof has been forthcoming, that in some, at least, filth has not played a conspicuous part.

With regard to typhoid fever and cholera, it is now known that the germicidal poison is excreted from the bowels, and that the focal discharges may infect water, or the germs may be conveyed to food by flies or insects. As to whether the said germs are frequently air-borne, however, is a point which has been by no means settled, some experienced observers holding that such is the case.

Speaking of the plague, Dr. Chapin denies that filth is a *sine qua non* in its production, and advances the statement that we might have a perfectly drained city with modern plumbing, efficient scavenging, and the purest of water; yet, if the inhabitants were careless in their habits and opposed to isolation, the disease would spread as in an undrained and poorly watered city.

This sweeping statement is hardly in accord with facts; it is true that the plague is of germ origin, but the mode of its dissemination is almost as much of a mystery as in the dark ages; nevertheless, proof upon proof has been in evidence, and indeed is at the present time, that the malady spreads most virulently amid unsanitary surroundings, and that where sanitation is good it makes but little headway.

It may be that the rat and flea are the most prominent disseminators, but there are yet numerous authorities who believe that the plague germ is conveyed by clothing and other fomites.

In the light of experience during the past decade it may be said that efficient sanitation is the best safeguard against plague.

Again, it must be something more than a coincidence that a disease like typhus fever has almost wholly disappeared, sanitary reforms surely were mainly responsible for the suppression of this disease.

Sufficient is not known concerning bacteria and parasites and their relation to disease to affirm that various other causes may not influence to a great extent the inception and spread of contagious maladies.

Personal cleanliness and efficient sanitation have in the past bulked largely in abolishing disease, and will do so in the future. The names of Chadwick, Pettenkoffer, and Shattuck will ever stand out conspicuously among those benefactors to mankind who have accomplished much in the fight against disease.

THE PRESYSTOLIC MURMUR OF AORTIC INSUFFICIENCY.

Under ordinary conditions, the vibrations that are necessarily generated by the passage of blood from auricle to ventricle and from ventricle to pulmonary artery and aorta, are lost in the sounds generated by other factors at the same time, and they are thus not separately audible. Did one possess sufficient acuity of hearing, it might be possible to differentiate the elements that go to make up the normal sounds of the heart; and one should be able to appreciate by sound the movement of the blood in its course through this organ. When, however, the blood current is obstructed, or when regurgitation takes place, the vibrations in question are intensified to such a degree as to give rise to readily detectable adventitious sounds. The auditory sense varies so widely in different individuals, and the interpretation of that which is heard is susceptible of such differing explanations, that it is not surprising that not rarely in a given case as many different opinions may be expressed with regard to cardiac murmurs present as there have been observers. Fortunately, the treatment depends rather upon the physical and functional state of the heart-muscle than upon the nature and the situation of the valvular lesion; and the therapeutic indication is usually the maintenance or the restoration of cardiac compensation, of circulatory equilibrium. It must be admitted, however, that this object can be the better and the more intelligently fulfilled if all that can be known concerning the lesion is known.

Nearly forty years ago, Dr. Austin Flint described a murmur—since known by his name—attending aortic insufficiency, occurring just before the systole, and only with difficulty distinguishable from that due to mitral obstruction. His explanation of the phenomenon was that the blood returned to the left ventricle by regurgitation from the aorta during the diastole, together with the blood entering from the auricle, causes approximation of the mitral leaflets through distention of the ventricle, and that the oncoming stream of blood from the auricle sets these leaflets into abnormal vibration. Other observers have attributed the more important influence to the returning current of blood falling especially upon the anterior mitral leaflet. The mechanism of the murmur, like its physical characters, is thus virtually the same, as that of mitral obstruction. The two conditions, however, are each characterized by certain peculiarities that afford a means for their differentiation. The whole matter has recently been subjected to careful analysis by Dr. W. S. Thayer (*Am. Jour. of the Medical Sciences*, November, 1901, p. 538) on the basis of seventy-four cases of aortic insufficiency observed at the Johns Hopkins Hospital, and in which the lesions were determined after death. As a result of this inquiry, the conclusion is reached that in uncomplicated cases of aortic insufficiency a rumbling, echoing presystolic or mid-diastolic murmur, limited to the region of the apex of the heart is a very common occurrence when carefully looked for in fully half of the cases. The characters of this murmur are in no way different from those commonly observed in cases of true mitral stenosis, with the exception that the murmur is usually of moderate intensity. It is, however, rarely associated with a tapping systolic impulse and a snapping first sound, which are the rule in cases of true mitral obstruction, while the pulse is large and characteristic of uncomplicated aortic insufficiency. In the absence of these sounds, and with a large pulse, the functional character of a presystolic murmur at the apex, associated with aortic insufficiency, is to be suspected, especially in cases in which there is no history of acute infectious processes such as are ordinarily associated with endocarditis, and in which there is evidence of well-marked arteriosclerosis. A presystolic murmur due to aortic insufficiency may, however, be associated with many of the clinical features of a true organic mitral obstruction.

HEALTH OF AMERICAN TROOPS IN THE PHILIPPINE ISLANDS.

Colonel Charles R. Greenleaf, late chief surgeon to the American troops in the Philippines, has submitted a report of the work of the medical department under his charge.

The report is a succinct narrative, and deals with the health of the troops, the mortality, sanitation, hospitals, transfer of invalids to the United States, transportation, Board of Health of Manila, health of prisoners of war, medical supplies, medical, personnel, and hospital corps.

The health of the troops continues to be good, the ratio of non-effectives to the whole strength having decreased still further. This improvement, says Colonel Greenleaf, is to a certain extent, no doubt, due to greater care in sanitation; but the greatest factor is that the regiments have been gradually weeded of their weaklings and chronic invalids. Service in the Philippines shows on a grand scale the operation of the law of the survival of the fittest. Seasoned soldiers of proper age, disciplined and intelligent enough to appreciate the primary rules of hygiene, and moderate in their habits, remain. The proportion of sickness among such men as these would be surprisingly small but for two adverse factors.

The first is the inevitable undermining of the strength of the most robust by tropical service; the second, the increase in venereal disease.

Typhoid fever has given little trouble, only a few sporadic cases having occurred from time to time.

Malarial fever has been, as usual, the most prevalent disease. The maximum in August, 1901, 21.55 per cent., and the minimum in April, 10.48 per cent. The percentage of dysentery remained about constant, while diarrhœal and gastric disorders exhibited a slight increase. Wounds and injuries showed little variation, and smallpox was infrequent.

Intestinal parasites, which are common throughout the islands, sometimes caused serious illness; but as a rule, these were responsible for only a small amount of sickness.

Colonel Greenleaf is particularly emphatic as to the grave aspect of the venereal disease question in the Philippines. In the period from September 1900 to April 1901, the increase in these affections rose from 8.97 to 15.42 per cent. of total sickness.

Colonel Greenleaf is of the opinion that lest our forces become seriously crippled, and an irreparable injury be done the people of the Philippines by those whose object is to help and elevate them, the subject must be looked squarely in the face, and dealt with as any other contagious disease.

Venereal disease is spreading from Manila as a focus outward into the provinces, and in time a large number of native women will be affected, and with less prospect of cure than their sisters in Manila.

Colonel Greenleaf thinks that a segregation of this class of women in Manila to a certain part of the town, a supervision of their health and a duly recorded treatment of the diseased should be systematically carried out.

The experience of the American troops in the Philippines differs not at all from that of soldiers of other countries, who have gone to tropical countries thickly populated, and which have been under the dominion of white men for a considerable time. Hong-Kong and the large cities of India are striking instances in support of this statement.

Laws strictly enforced regulating prostitution have been shown in these places to be the only effective means of controlling venereal diseases.

The Contagious Diseases Act in India did much to check venereal disease, its repeal alone proved its merits.

Sentimentality or false modesty should not be allowed to stand in the way when the point at issue is the health and well-being of a large number of American citizens.

Sanitation has progressed in Manila. The chief difficulty with soldiers in the field and even in the city itself is to obtain a supply of absolutely pure water, and when such is obtainable by means of sterilizers to induce the men to take the extra exertion necessary to procure the beverage free from hurtful bacteria and parasites.

The hospitals at the time of the report were in good condition, and a well-earned tribute of praise is paid to the work of the Army Pathological Laboratory.

The transportation of invalids to the United States has been on the whole successfully conducted.

An interesting description is given of the work of the Manila Board of Health, which has been productive of excellent results.

Colonel Greenleaf renews the applications made in former reports for a larger force of medical officers to do duty in the Philippines. He again points out that the number there is altogether inadequate.

The report concludes with a eulogy of the Hospital Corps, the members of which appear to have greatly distinguished themselves by their intelligence, knowledge, and self-reliance.

Colonel Greenleaf's experience in the Philippines invests his statements with much force, and his views, especially with regard to the control of venereal diseases in the islands, are deserving of attention at the hands of the authorities.

THE CARNEGIE INSTITUTION.

MR. CARNEGIE's gift of $10,000,000 is to be transferred in 5-per-cent. bonds to a Board of Trustees elected by the incorporators of the institution.

The purpose of the institution is expressed by Mr. Carnegie as follows:

"It is proposed to found in the city of Washington, in the spirit of Washington, an institution which, with the coöperation of institutions now or hereafter established there or elsewhere, shall, in the broadest and most liberal manner encourage investigation, research, and discovery; encourage the application of knowledge to the improvement of mankind; provide such buildings, laboratories, books, and apparatus as may be needed, and afford instruction of an advanced character to students, whenever and wherever found, inside or outside of schools, properly qualified to profit thereby.

Among its definite aims is to promote original research, paying great attention thereto, as being one of the chief purposes of this institution. To enable such students as may find Washington the best point for their special studies, to avail themselves of such advantages as may be open to them in the museums, libraries, laboratories, observatory, meteorological, piscicultural, and forestry schools, and kindred institutions of the several departments of the Government. To insure the prompt publication and distribution of the results of scientific investigation."

The scope of the whole scheme is conceived on wide and generous lines, and should not fail to advance the cause of education in this country.

The fact is especially gratifying that so much attention should have been paid to scientific research of every description.

The MEDICAL RECORD has always emphasized the need of large endowments for this purpose, and has insisted that, without the necessary facilities for this kind of work, America cannot successfully compete with those European countries which are well provided in these respects.

THE FOOT SOLDIER'S SHOE.

In an article in the MEDICAL RECORD, written at the commencement of the Spanish-American War, much stress was laid on the necessity of providing our soldiers with suitable and comfortable footwear. The requirements of an infantry soldier's ideal shoe were then briefly sketched.

The proper covering and protection of the soldier's foot is the most important item of an infantry soldier's accouterment.

All the most celebrated leaders of armies, including Marshal Saxe, Napoleon, and the Duke of Wellington, were agreed on this point. Notwithstanding this unanimity of opinion among generals that well-fitting shoes are of supreme moment to foot soldiers, and that an army of men footsore are comparatively useless, the footgear of infantry troops in all parts of the world is notoriously very far from perfect.

It is announced in the *Lancet*, December 7, that Surgeon-Major Berthier of the French claims to have invented an almost ideal boot. Surgeon-Major Berthier's "brodequin haut" is eight inches in height, without reckoning the heel, and is closed in front by two flaps, which are laced in a novel manner. Below on either side there are four eyelets, which should be tightly drawn together over the instep, while above there are five pairs of hooks and two eyelets which may be approximated tightly or loosely, according to circumstances.

Meyer of Zurich is regarded in Europe as the chief authority on soldiers' footwear, but Surgeon-Major Berthier disagrees in toto with the principles upon which the Meyer shoe is constructed, claiming that the soles and uppers are not rational.

There is one feature of Surgeon-Major Berthier's shoes which will not meet the universal approbation of experts. The French surgeon is in favor of heels of a considerable height, asserting that this elevation "facilitates marching by diminishing the muscular work demanded at each uprising on the toes. At the same time a certain inclination of the trunk forward is rendered necessary, which is favorable to progress, forcing the legs to bend and lengthening the step."

Heels of moderate height are probably best adapted for use on soldiers' shoes, although many hold that low heels are the best calculated to give comfort and ease, when much walking is to be done. Certainly authoritative opinion is adverse to very high heels, and at any rate, they should be wide.

INFORMATION REQUIRED REGARDING PULMONARY TUBERCULOSIS.

Dr. Daniel Lewis, the New York State Commissioner of Health, is sending to physicians of the State a series of questions for the purpose of obtaining some fundamental facts concerning pulmonary tuberculosis.

The primary object of these inquiries is to learn, with such accuracy as possible, the number of the population of the State thus affected.

A secondary consideration is to learn something of the conditions which surround them, as indicated by the questions, as they may apply to individual localities.

The questions ask for the initials of the sick, age,and sex, residence, occupation, nationality, duration of disease, source of infection, family history of tuberculosis, whether others of the household are affected, sanitary surroundings, tenement houses, and precautions to prevent spread.

It is not proposed to secure a registry of cases of consumption, but to accumulate data. which will make the Health Department better able to cope with the problem before it in the State.

The plan seems to be a good one, and the medical profession will be acting in the interests of the public health if it will afford all the information it can.

THE MILITARY BOARDS OF HEALTH AND OF CHARITIES IN PORTO RICO.

No reading American can fail to be aware of the good results which have followed the establishment in the towns of Cuba of effective sanitary measures. Little, however, has been heard of the equally good results produced by similar methods in Porto Rico.

An epitome of reports of the Superior Board of Health, and the Board of Charities of Porto Rico, has been published recently, and provides some very instructive reading.

Lieutenant-Colonel John Van R. Hoff, U. S. A., was the leader in this sanitary reform movement, and upon his recommendation the Superior Board of Health was established, and of which he was appointed President.

Perhaps the most important work done by this board has been the task of vaccinating the entire population with lymph from its own vaccine station. But the members of the board have been tireless in their endeavors to introduce a system of sanitation complete in all details, and it must be said that their efforts have been crowned with unqualified success.

In addition to this, Colonel Hoff, as President of the Board of Charities of Porto Rico, together with his conciliatory, paternal and humane service in the cause of humanity, by relieving the great destitution consequent on the hurricane of August 8, 1899.

The board received and distributed thirty-two million pounds of food and many thousand garments, built roads, cleaned streets, rebuilt houses, planned the reforestation of a sugar colony, and did much other necessary charitable and social work.

In Cuba and Porto Rico Americans can point with pride to the successful administration of their military and army medical officers. The improvements brought about by their agency should alone suffice to justify the American occupation of these islands.

INOCULATION AND ENTERIC FEVER

Dr. Raymond Crawford, writing in the *Therapeutic Gazette*, December 15, refers to an analysis by Elliot and Washbourne of statistics of 262 cases of enteric fever in South Africa, which they compared with statistics of the Maidstone epidemic in 1897, of the Metropolitan Asylums Board, and of Johns Hopkins Hospital, with a view to showing whether the disease in South Africa was identical with that met with in England and America.

Their general conclusion was that South African enteric fever is identical with that seen in England and America, and that inoculation is of little practical value.

Dr. Crawford is inclined to dissent from this conclusion as somewhat premature. He thinks that a full analysis of the intervals between inoculation and the attacks is necessary before coming to a definite decision on the point, as it has never been claimed that inoculation provides more than a very temporary immunity.

Others who have had a large experience in enteric fever in South Africa, consider that some degree of immunity is almost unquestionable for a period of a few months, and that the severity of the attacks is also diminished by inoculation.

The question of inoculation against enteric fever is still an open one. The evidence for or against has not as yet been decisive enough to warrant a definite conclusion. When the results from its use during the South African war have been collected and tabulated, an authoritative opinion as to its immunizing effects may be expected. Until then views expressed do not carry sufficient weight to uphold or discredit the method.

AMERICAN ARMY DENTAL CORPS

The establishment of a dental corps in the American army is largely a result of the Spanish-American war, and of the campaign in the Philippines. The government has realized the importance of this branch of military hygiene.

The dentist of the present time is a skilled operator, indeed a specialist, and it was not to be expected that the army surgeon could perform delicate dental work, or treat successfully various ailments of the teeth, gums, and jaws.

The Army Dental Corps consists of thirty members, is organized on the contract system, belongs to the regular establishment, serves officers and enlisted men of the regular and volunteer armies. Each has the relative rank of first lieutenant and receives $150 a month, and quarters when serving with the troops.

Of the thirty men appointed, three compose the examining board of the others, some are in Cuba and Porto Rico, but the majority are in the Philippines, where there is the greatest need of their skill.

"The intention is not," says Surgeon-General Sternberg, "to fit up the entire army with complete artificial teeth, or to do fancy crown or bridge work. Men enlist for only three years. Their teeth must appear sound or they will be rejected, but few of them have their teeth in as fine condition as a gentleman of means outside the army would. We do not propose to do any extravagant repairing unless a man sustains injuries in the service necessitating it."

The organization of the Army Dental Corps is in the way of an experiment, but it seems certain that the results will be so satisfactory that the dentist will be regarded as necessary an adjunct to the army as is the surgeon and the veterinarian.

THE FUNCTIONS OF APPETITE

The *Literary Digest*, of a recent date, contains an epitome of the lectures of Prof. J. P. Pawlow of St. Petersburg on "The Work of the Digestive Glands," which have recently been translated from Russian into French and reviewed in the *Revue Scientifique* (September 7). The *Literary Digest* commences its article by remarking that too little account, it is thought, is taken by physiologists of the functions of appetite. As these functions belong in one sense to the domain of psychology, the physiologists are apt to devote themselves wholly to the nutritive value of foods, leaving out matters of the taste entirely. Professor Pawlow deprecates this neglect, and fully recognizes the part played by appetite, not only in ordinary digestive processes, but in bringing on or in curing diseased conditions of the digestive organs.

Dr. Pawlow declares himself convinced that a grave mistake is made in not giving special heed to appetite, and that to regard a poor appetite as a subjective symptom of slight importance is a gross error of judgment.

The Russian professor thinks that it is the duty of the physician not only to regulate the lives of certain individual patients according to the principles of promoting digestion by the means best adapted to the case of the sufferers, but also to endeavor to extend and to explain widely a knowledge of the importance of the act of eating.

"If we consider," says Dr. Pawlow, "the influence of the psychic factor in digestion, the question of condiments appears in a new light. Justification is found for the statement which has long been made on empirical grounds—that it is not sufficient to provide nutritious food at meals; it must also be agreeable to the taste."

TELEPHONES IN LONDON

Unlike New York, or indeed any large American City, the means of inter-communication by telephone in London is limited. This backward condition of things is now about to be remedied, and the work of the British metropolis it is announced will soon be pervaded by the method of transmitting the human voice as necessary to the citizens of this continent as the electric car or breakfast.

The London Hospital, December 14, has an editorial on the matter, the writer of which does not appear to regard the coming universal installation of telephones in the big city as an unmixed blessing. He dreads, or feigns to dread, that such an event may be of no especial service to the medical practitioner, but perhaps the reverse, and warns each and all that the impending invasion of London by a telephone system on so extensive a scale will be attended with many drawbacks.

The idea of the London medical journalist would seem to be that the telephone will render the doctor too get a table, so to speak, and that he will be ofttimes at the mercy of bores and patients who will, by the agency of telephone, endeavor to obtain cheap advice. In short, he fears that the unfortunate physician may be compelled against his will to listen to the hair-brained chattering of irresponsible frivolity.

So far as America is concerned, it can be asserted in perfect good faith that to scarcely any class has the telephone proved a greater boon than to the medical man. He may sit in his office with telephone on desk, and hear reports from his patients, and can decide when such or such a one will require his presence. The merits of the telephone system are in fact so obvious that it is needless to further dilate upon them.

Telephones here are not entirely perfect yet, but the benefits derived from their use greatly counterbalance their defects.

London medical men in time to come will wonder however they managed to get along without such a convenience.

"Tipping the Nurse."

We have heard not a little of late concerning a division of fees between the attending physician and the consultant, especially the surgical consultant in cases in which an operation is performed, and it is to be feared that this practice does exist in some places, though it is hoped in not any considerable degree, and certainly not among reputable men. Despicable as is such a course, it appears that even a worse condition of affairs may exist, as is indicated by a communication to the *Lancet* from a medical practitioner who calls attention to the practice of certain medical men (unfortunately for the profession far too numerous) of paying sums varying from 1s. to half the confinement fee or more to the nurses in attendance. Such a state of affairs can only exist when and where the practice of medicine is looked upon as a business rather than a profession, and it is comparable with the conduct of a certain, and fortunately small, class of lawyers who are responsible for the institution of suits for damages in cases that may charitably be designated as of doubtful character.

The First Award of the Nobel Prizes.

Alfred Nobel, the inventor of dynamite, and who left his immense fortune of over $9,000,000 to found prizes, has an appreciative memoir in the *American Review of Reviews*, January.

According to the terms of his will, the annual interest upon the whole of his fortune was to be divided into five equal portions, which were to be distributed every year as rewards to the persons who had deserved best of mankind in five departments of human activity.

One part to go to the man who shall have made the most important discovery or invention in the domain of physical science; another, to the man who shall have made the most important discovery or introduced the greatest improvement in chemistry; the third, to the author of the most important discovery in the domain of physiology or medicine; the fourth, to the man who shall have produced the most remarkable literary work of an idealistic nature; and, finally, the fifth, to the man who shall have done the most or best work for the fraternity of nations, the suppression or reduction of standing armies, and the formation and propagation of peace congresses.

The first award of these prizes has just been made. The medical prize went to Dr. Emil Behring, professor at Marburg, Germany, and the discoverer of antitoxin for diphtheria. In the department of chemistry, Dr. J. H. Van't Hoff, a native of Holland, who has held a professorship for the past six years in the University of Berlin, received the prize. He was for some years professor of physical chemistry at Amsterdam. While there he contributed largely to the world's knowledge of molecular physics, and is regarded as the founder of a new system of stereochemistry.

William Röntgen was chosen as the recipient of the prize in physics. Röntgen, who is now in his fifty-seventh year, is, like Behring, a professor at Marburg.

Dr. Henry Dunant, the founder of the Red Cross Society, was selected, together with M. Frederick Passy, for the prize for the encouragement of peace and arbitration, which was equally divided between them.

The $20,000 which comes to Dr. Dunant is not only well deserved, but will relieve him from abject poverty, as, when the award was made, he was reported ill and destitute in a Swiss hospital.

Berthelot, the Greatest Living Chemist.

Some three months ago honor was paid by the scientific men of all civilized nations to Virchow, the renowned German pathologist, on the occasion of his eightieth birthday.

At the Sorbonne, in Paris, a like gathering was held, to commemorate the fiftieth anniversary of the publication of M. Berthelot's first memoir. The President of the French Republic presided, assisted by the entire cabinet, by representatives of all departments of the government, and by delegates from the learned societies of France and of other nations.

Pierre Eugene Marcelin Berthelot was born in Paris on October 25, 1827, and has lived in that city throughout his life.

As a student he distinguished himself in history and philosophy, as well as in science, but has since his undergraduate days made natural science his especial study. In 1851 he was appointed assistant in chemistry at the Collège de France.

His chief work has been in chemistry. During fifty years he has written 600 memoirs, and has published treatises on organic chemistry, on chemical mechanics, on agricultural chemistry, besides works on the philosophy of science and on the history of alchemy.

M. Berthelot's name is mainly associated, however, with two remarkable discoveries—the synthesis of organic compounds and thermochemistry.

He disproved Lavoisier's theory that chemistry was purely an analytical science by demonstrating that chemistry could also perform syntheses.

In 1862 Berthelot, by the agency of the electric arc, effected the direct combination of carbon and hydrogen, forming acetylene.

By his creation of thermochemistry the evolution of smokeless powder was rendered possible.

The world of commerce has benefited largely by the discoveries of Berthelot, and medicine is indebted to him for a number of new drugs.

None of his discoveries were patented, so that pecuniarily he has profited nothing from them.

He is a professor of the Collège de France, a member of the Academy of Sciences, of the French Academy, a member for life of the Senate, an ex-minister of Foreign Affairs, and a member of the principal academies and scientific societies of Europe.

The names of Pasteur and Berthelot will go down to posterity, linked together, as those of the greatest French scientists of the latter half of the past century.

News of the Week.

Gifts to Hospitals.—The Norwegian Lutheran Deaconesses' Home and Hospital in Brooklyn has received an endowment of $[illegible] from a resident of Newark, N. J. The gift is intended, it is said, as a memorial to Severin S. Skougaard, the Norwegian pastor. The Norwegian Hospital, which is at Forty-sixth street and Fourth avenue, was established twenty years ago. Plans for a new building to cost over $[illegible], close to, opposite the present building, have been completed, and work on it will be begun as soon as the money in hand warrants the undertaking.

At the annual reception in the babies' wards of the Post Graduate Hospital held one day last week Dr. D. B. St. John Roosa, President of the Post-Graduate Hospital Association, announced that a man, whose name is withheld, has made a gift of $100,000 to be applied to the liquidation of the hospital's debt, on condition that the remaining $300,000 of the hospital's indebtedness be raised by other means.

Tubercular Milk in New York City.—The State Commissioner of Agriculture recently discovered a herd of tuberculous cows in a dairy from which some of the city milk supply is obtained. Fifty cows out of a herd of 108 have died of tuberculosis during the past six months. The herd was at once quarantined, and the animals which were undoubtedly tuberculous were killed, the others being kept under strict observation. One of the members of the Agricultural Committee of the State Senate makes the alarming assertion that the discovery is simply indicative of the conditions which prevail to a certain extent throughout the dairy center of the State.

Fraud Order Against a Diploma Mill.—The Postmaster-General issued an order denying the use of the mails to the "Central University of Medicine and Science," and J. W. Norton Smith, President, of Jersey City. The university represented that it was an incorporated institution in good standing and that it had an extensive medical faculty. To those desiring to practise medicine it sold diplomas, at prices ranging from $5 to $20, according to the ability of the applicant to pay. The scheme is identical with that once operated in Chicago by James Armstrong, under the title of the Metropolitan Medical College. Armstrong was tried in the United States Circuit Court and sentenced to one year in jail. The Department of Justice will probably take action against J. W. Norton Smith, who is named in the fraud order as the promoter of the present scheme, and who has already had trouble with the local authorities.

The Surgeon-General of the New Jersey National Guard.—Governor-elect Murphy of New Jersey, has written a letter to Dr. John D. McGill of Jersey City refusing to accept his resignation as Surgeon-General of the National Guard of the State of New Jersey. He urged Dr. McGill to serve during his administration and Dr. McGill has consented to do so.

The Bacillus of Canities.—It is reported that Metchnikoff has discovered a microorganism which he calls *Bacillus pigmentophagus*, which is the cause of the loss of pigment in gray hair. This bacillus is constantly present in the hairy parts, he says, but is not virulent, and the tissues in health easily keep it under; but when the resisting power of the economy is weakened by age, especially if there is added the action of poverty or of mental or physical strain, the bacilli gain the upper hand and rapidly destroy the capillary pigment.

Bob Veal in this City.—A bill has been introduced into the Legislature forbidding the slaughter for the purpose of selling, or sale within the State, or importation into any town within the State for food of any calf or carcass of the same, or any part thereof, except the body, unless it is in good healthy condition, and at least four weeks of age at the time of killing. Railroads are forbidden to transport any veal of the prescribed youth. It is asserted that a large amount of bob veal is consumed in this city.

The Study of Scarlet Fever.—The Memorial Institute for Infectious Diseases, founded in Chicago by Mr. and Mrs. Harold McCormick, in memory of their son John Rockefeller McCormick, who died a year ago of scarlet fever, was recently incorporated. The institution has been generously endowed, but for the present it will have no building of its own. At the beginning its researches will be devoted to scarlet fever solely, but the work will be carried on in some other medical institution. It is the intention, however, to house the institution later in a building of its own and to broaden the scope of its inquiry, so that it will include all that its name indicates.

A Deserting Russian Naval Surgeon.—The Supreme Court in Washington recently decided that a liberal construction of the treaty between the United States and Russia demanded the delivery to that country of Dr. Leo Alexandroff, a deserter from the Russian warship *Variag*, notwithstanding he had renounced allegiance to that country and signified his intention of becoming an American citizen. He came to the United States a year or so ago, with a detail of men, to act as Assistant Surgeon on the *Variag*, then building at Philadelphia, when she should be completed, but almost immediately deserted, and announced his intention of remaining in this country and becoming a citizen. Three of the justices vigorously dissented from this decision, holding that the case was not covered by the express provisions of the treaty, and in the absence of such express provision there was no power of the executive or the judiciary to surrender a fugitive.

A Centenarian Practitioner.—Dr. John Wood, said be the oldest practising physician in the world, celebrated his one hundred and first birthday at Coffeyville, Kan., on January 4. When Kansas was admitted into Statehood, he was a United States commissioner, and John Brown was twice brought before him, once charged with murder and once with harboring fugitive slaves.

Smallpox in London.—But little headway is being made by the health authorities in London against the present outbreak of smallpox. From May up to January 10, there were 2,273 cases reported to the authorities, and the number of new cases averages from twenty-five to thirty each day. The number of cases under treatment on January 10 was 878. The patients in London are not treated in hospital buildings, but in a number of hospital ships fifteen miles down the Thames, or in shelters erected in unfrequented districts on the banks of the river. Houses are rigorously inspected, and where infection has been found they are thoroughly fumigated, and when the diseased person is removed, the other inmates are quarantined. The death rate during the present epidemic has been 14 per cent. in the cases of persons who had been vaccinated, 65 per cent. in doubtful cases, and 50½ per cent. when the patients had not been vaccinated. The health authorities have decided to erect buildings for the accommodation of 800 additional patients, in order that they may be prepared to cope with the situation, should the present epidemic assume larger proportions.

The Carnegie Institution.—Ex-President Gilman of the Johns Hopkins, one of the trustees of the new institution for the foundation of which Mr. Andrew Carnegie has given $10,000,000, recently outlined its scope in a lecture delivered in Baltimore. The plan as outlined by Dr. Gilman is more universal than the university, and is broad enough to cover the whole field of human effort and achievement. It involves no rivalry with existing institutions, nor yet the establishment of a new one in the sense of a separate college or university with a resident faculty. Its privilege will be extended to anybody, young or old, white or black, man or woman, graduate or undergraduate, native or foreign. If a mechanic, a student, an inventor, or an institution is found to be developing a special line of work toward the welfare or improvement of mankind, such individual, or institution will be considered a proper object for assistance, if such is needed to insure success. It is not intended to build expensive permanent laboratories, when necessary laboratories may be constructed for specific purposes, but they will be of a temporary character. There will be no imposing group of buildings, and such administration buildings as may be necessary will be very modest. There will be no terms of admission or graduation, and no prescribed courses of study. It will be for the encouragement of practical workers, and not an institution for the promotion of higher learning or of learning of any degree. It will be a corporation for the creation of knowledge rather than for its promulgation. Doubtless, medical research, along with other departments of scientific and learned investigation, will profit by this example of Mr. Carnegie's philodory.

Philadelphia County Medical Society.—At a stated meeting held January 8, Dr. Ernest W. Kelsey gave a lantern exhibition illustrating many interesting features of "Arctic Alaska," observed during a service of sixteen months as surgeon to the Alaska Commercial Company.

Camden City Medical Society.—At the annual meeting held January 7, the following officers were elected for the ensuing year: *President*, Dr. Robert Casperson; *Vice-President*, Dr. J. F. Leavitt; *Secretary*, Dr. V. de Grofft; *Treasurer*, Dr. W. H. Pratt; *Historian*, Dr. Daniel Strock; *Librarian*, Dr. Joseph H. Willis.

Membership in Medical Societies.—A writer in the *Journal of the American Medical Association* estimates that there are 77,000 physicians in regular practice in the United States who belong to no medical society whatever. This estimate is based upon the assumption that there are 110,000 regular physicians in the country, about 33,000 of whom are members of one or more local, State, or national societies.

Light Anæsthesia.—The Russian surgeon Professor Minin is using the violet rays of electric light as a substitute for cocaine in surface operations. It is claimed that they are antiseptic as well as anæsthetic.

Prize Essays for Sanatorium Plans.—The following are the conditions of competition for the prizes offered, as was announced last week, for the best essays and plans for the sanatorium about to be established in England, through the donation of £200,000, for the treatment of tuberculosis: 1. Medical men of all nationalities may compete. The papers may either be the work of a medical man, or the joint production of a medical man and an architect. 2. The sanatorium is intended for 100 tuberculous patients—fifty male and fifty female. 3. Of the total number of beds, eighty-eight will be assigned to the more necessitous classes, while twelve will be reserved for the well-to-do. 4. The accommodation for all patients is to be comfortable, a separate room being provided for each. Superior arrangements to be made for the more wealthy patients. 5. It may be taken for granted that the sanatorium will be erected on an levated and sloping site, with a sunny exposure, and well sheltered from cold winds. It will have a farm at a convenient distance, and be surrounded by extensive grounds, well-wooded, and affording ample space for exercises of various kinds. The soil will be dry and permeable, and the water supply abundant. 6. The sanatorium must be fitted with the latest sanitary arrangements, and equipped with all requirements for scientific research. Provision should also be made for the recreation of the patients. 7. Economy in construction will be an important consideration, but it must not interfere with the reasonable comfort of the patients or the efficiency of the institution. 8. The essays must be in English, and typewritten. 9. The essays must not bear the name or names of their authors, but should have a motto, and each essay should be accompanied by a sealed envelope bearing the motto on the outside and containing the full name and address of the author or authors inside. 10. All essays and plans must be sent, postage paid, on or before the 15th of April, 1902, to one of the Secretaries of the Committee: Dr. P. Horton-Smith, 15 Upper Brook Street, W. London; or Dr. J. Broadbent, 35 Seymour Street, W. London. 11. Three money prizes of £500, £200, and £100, respectively, will be awarded in order of merit, on the recommendation of the Advisory Committee, for the three best essays, provided they come up to the requisite standard of excellence. Brevity will be an important consideration, and a summary of the main features of the scheme should be appended to the paper. Unsuccessful papers will be returned to the authors.

A Biological Laboratory at Vassar College.—The New England Building at Vassar College, so named because the funds for its erection came from New England, was formally opened and all the students were invited. Although generally styled the Biological Laboratory, the building is also designed for geology and physiology, and answers a pressing need in each of these directions. In external structure the building is Colonial, built of red brick with marble trimmings. In the basement are three rooms for geology, one for botany, an aquarium room, a dark room for photography, and a dark room for plant physiology, besides storage and coat rooms. On the first floor are a geology lecture and a geology recitation room, a botany and a zoology room; on the second floor are the physiological laboratory, general laboratory, lecture room, preparatory room, office, and museum.

The New York State Charitable Institutions.—In his annual message to the Legislature, Governor Odell had a good deal to say of what he regards as the unbusinesslike and extravagant administration of the various charitable institutions of the State. He gives the figures of the per capita cost of maintenance at the different reformatories, showing a difference between the highest and lowest of $1.43 per week. This margin of difference, he says, cannot be explained in any other way than by more expensive administration, as the cost of supplies does not vary enough to account for it. He adds that it is not alone in the expenditures for maintenance that the waste of public money is exemplified, but also as to the demands for improvements, "which are dictated either by sentiment or ideas that are both unbusinesslike and undesirable." As illustrating this tendency toward extravagant expenditures, he mentions some of the items asked for by various institutions. One asks for a mortuary at a cost of $4,500, another a railroad switch at a cost of $10,000. An idiot asylum wants a propagating house for flowers, at a cost of $3,200; another institution asks for a stable for officials' horses and carriages, to cost $5,000; another asks for an appropriation of $125,000 for the purchase of a [illegible] and civil service, a cottage for the Forest at a cost of $[illegible]. As a remedy for the lack of uniformity in expenditures and a curb on expensive appropriations the Governor recommends that the present State Board of Charities be charged with the care and administration of our charitable institutions and that visiting committees be appointed annually and be empowered to visit and report to the Governor as to the conditions found; that the present Boards of Managers be abolished and the State Board of Charities be permitted to recommend, subject to the approval of the Governor, a superintendent, either from their own number or otherwise, with a salary of $5,000 per annum, who shall have full authority, under such regulations as may be adopted by them, subject to executive approval, over all charitable institutions. He believes that a very great saving will be effected if these recommendations are adopted; but the State Board of Charities dissents from this view, and has protested vigorously against the abolition of the boards of managers of the several charitable institutions.

Increase in Smallpox.—The number of cases of smallpox reported to the Philadelphia Bureau of Health for the week ended January 11 was 131 with fifteen deaths.

A Victory for a Hospital Medical Staff.—The National Hospital for the Paralyzed and Epileptic in London seems to have got over its troubles. The recommendations of the committee have been carried by the governors. The staff has obtained the representation it desired, and the director has been got rid of—with a gratuity of £600 and a pension of £450. He evidently makes a good thing of it, and this raises the query as to the use in this way of money subscribed for the sick.

The staff dined together a night or two ago, and presented their secretary with a piece of plate.

Vaginal Cancer; Corrigendum.—Dr. W. Roger Williams writes: Will you kindly correct a misprint which occurs in my paper on "Vaginal Cancer" in your issue of November 30? I am there represented as saying that "4.3 per cent. of all cancers in women are of vaginal origin."

This is a mistake, the printer's devil having played havoc with the decimal point. I have found that less than a moiety per cent. of all cancers in women are of vaginal origin—viz., .43 per cent.

The Samuel D. Gross Prize of $1,000.00 has been awarded to Dr. R. H. M. Dawbarn of this city for his essay on the "Treatment of Certain Malignant Growths by Excision of the External Carotids."

The Season's Diseases.—The influence of the season is still exhibited in the mortality returns. Of the 488 deaths reported to the Philadelphia Bureau of Health for the week ended January 11, 72 were due to pneumonia and 63 to pulmonary tuberculosis. Four deaths were attributed to influenza and 18 to inanition. Other important causes of death were heart disease (52 cases), nephritis (34), apoplexy (21), smallpox (16), inflammation of the brain (15), convulsions (14), inflammation of the stomach and bowels (14), apoplexy (13), diphtheria (13). The total number of deaths for the week was twelve more than for the preceding week and thirty-five more than for the corresponding week of the previous year. There were reported for the week 90 cases of smallpox, 88 of diphtheria, 66 of scarlet fever, 16 of typhoid fever.

The Health of Havana.—The report of Major Gorgas, Havana's most efficient sanitary officer, on the health conditions of the city for November is of the same tenor as those that have preceded it each month. A comparison of the statistics shows that the sanitary condition of the city is excellent, each month showing a steady improvement over the corresponding months of the preceding year. During the last eleven years the average number of deaths for November has been [illegible]. In November this year there were 443 deaths. The death rate was 19.58, which compares favorably with cities of the same size in the leading civilized countries of the world. During November there were no cases and no deaths from yellow fever. That can be said of no preceding November since 1762. During the last eleven years the average number of deaths from that disease in November has been 48.

Society of Gymnasium Directors.—The fifth annual meeting of this society was held at Columbia University last week, under the presidency of Dr. R. Tait McKenzie of McGill University, Montreal. The object of the organization is declared to be the advancement of physical education in institutions of higher learning, and the theoretical and practical questions pertaining to gymnastics in these institutions. Men who have had three years of professional teaching experience are eligible for membership, provided they are members of the American Association for the Advancement of Physical Education. The following officers were elected: *President*, Dr. Paul C. Phillips of Amherst College; *First Vice-President*, Dr. Edward Hitchcock of Cornell; *Second Vice-President*, Dr. Frederick E. Parker of Brown; *Secretary and Treasurer*, Dr. James A. Babbitt of Haverford; *Members of the Council and Admission Committee*, Dr. William G. Anderson of Yale, Dr. Dudley A. Sargent of Harvard, and Dr. R. Tait McKenzie of McGill. The next meeting will be held at Columbia during the Christmas holidays in 1902.

The American Electro-Therapeutic Association will hold its twelfth annual meeting at the Kaaterskill, Catskill Mountains, N. Y., on Tuesday, Wednesday, and Thursday, September 2, 3, and 4, 1902. The officers of the association are: *President*, Dr. Fred H. Morse, Melrose, Mass.; *Secretary*, Dr. George E. Bill, Harrisburg, Pa.; ***Treasurer***, **Dr. R. J. Nunn**, Savannah, Ga.

Dr. W. D. Lederman of this city has been appointed to the advisory board of the St. Joseph Hospital, Silver City, New Mexico; an institution established for the treatment of pulmonary tuberculosis.

College of Physicians of Philadelphia. Section on General Medicine.—At a stated meeting held January 13, Dr. D. J. Milton Miller showed "A Case of Myxœdema" that had been exhibited to the section five years previously, and in which the more obtrusive phenomena were held in abeyance by intermittent administration of thyroid gland. Dr. Miller also read a paper entitled "A Case of Pneumococcic Arthritis Complicating Acute Croupous Pneumonia," in which bacteriologic investigation disclosed the presence of diplococci in the fluid aspirated from the inflamed joint. Dr. John H. W. Rhein reported two cases of "Insanity of Doubt." Dr. J. M. Anders read a paper entitled "A Case of Aortic Stenosis Ending in Sudden Death; Dilatation of the Aorta at Its Root and Marked Stenosis of the Vessel Beyond." The development of accentuation of the aortic second sound in a case in which previously there had been the physical evidences of aortic stenosis with an enfeebled aortic second sound, together with an increased area of dulness at the base of the heart, suggested during life the dilatation of the aorta that was found after death. Dr. Augustus A. Eshner exhibited "A Case of Aortic Obstruction and Insufficiency" in a man forty years old with a history of previous attacks of scarlet fever, smallpox, and influenza, but none of syphilis or of alcoholic excess. The area of cardiac dulness was considerably increased, a diastolic thrill was palpable over the body of the heart, at its base and to the right of the sternum in the third and fourth interspaces, the first sound of the heart was accompanied by a blowing murmur and was followed by a loud, rough, musical murmur, friction sounds were audible at base of the heart, and systolic retraction was visible upon the front and back of the lower portion of the left half of the chest. Dr. F. A. Packard was elected President of the section and Dr. S. McC. Hamill clerk for the ensuing year.

Obituary Notes.—Dr. JOSEPH S. CARREAU of this city died suddenly on January 7 of disease of the heart. He was born in Canada fifty-three years ago, and was graduated from the New York University Medical College in the class of 1874.

Dr. WILLIAM AUGUSTUS PIERREPONT died of heart disease at his home in Brooklyn on January 6, at the age of forty-six years. He was born in Brooklyn, and after a preparatory education he studied law at Columbia University, receiving a degree in 1876. He did not practise law, but took a course in medicine in the New York University Medical College, being graduated in 1882. The following year he became resident physician and surgeon of the Brooklyn Hospital, where he remained for two years. After that he practised with Dr. Jasper Griswold in Manhattan. Of late years, Dr. Pierrepont had not practised.

Dr. G. H. WILSON of Meriden, Conn., a homœopathic practitioner and ex-mayor of the city, died on January 10 at the age of seventy-eight years. He was a native of Stockbridge, Mass., and was graduated from the Berkshire Medical College, Pittsfield, in 1849.

Dr. ALFRED N. MAHON, son of Dr. J. B. Mahon of Pittston, Pa., died in that city on Saturday night of nervous prostration, following typhoid fever, which he suffered in the Philippines while in the service of the United States as a surgeon on the transport *McClellan*. He was in the service two years, returning home last November broken down in health. He was twenty-nine years old.

Dr. J. J. BUCHANAN, Assistant Surgeon United States Navy, cut his throat with a razor January 10, while in delirium at his ward in the Naval Hospital on Coasters' Harbor Island. Dr. Buchanan was assigned to duty aboard the *Constellation* on January 2. About that date he was taken ill with typhoid fever and was sent to the Naval Hospital. His nurse was out of the ward, when he left his bed to-day and cut his throat several times, dying immediately. Dr. Buchanan recently received his appointment from Texas, coming to this station from the cruiser *Columbia*. He was twenty-four years old.

Dr. WM. C DIXON died at Philadelphia on January 6, as the result of appendicitis, at the age of sixty-two years. He was graduated from the Medical Department of the University of Pennsylvania with the Class of 1860, and at the outbreak of the Civil War he enlisted as a Surgeon in the army, being assigned to the Satterlee Hospital in West Philadelphia. He was a visiting physician to the Pennsylvania Hospital for the Insane and examining physician for the insane department of the Philadelphia Hospital, attending physician to the Industrial Home for Blind Women and visiting physician to the Shelter.

Dr. CHAS. FRANCIS CARPENTER died at West Chester, Pa., on January 5, at the age of seventy-six years. He was graduated from the Medical Department of the University of Pennsylvania in 1849. In 1857 he went to Louisville, Ky., where he was engaged in practice forty years, and where during the Civil War he had charge of the army hospital. He returned to West Chester three years ago. He had been an extensive traveler.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

REORGANIZATION OF THE ARMY MEDICAL SERVICE—DR. GOODHART'S PURVIS ORATION—PRINCE OF WALES' HOSPITAL FUND—SMALLPOX—LIVINGSTONE COLLEGE.

LONDON, December 27, 1901.

ARMY reorganization occupies a considerable share of public attention even in this holiday season. Lord Rosebery's cry for efficiency at the War Office has been reechoed in all directions and is being applied to the Medical Department. Possibly that may derive some benefit from the discussion that has been evoked, for it is clearer than ever that the scheme of reform of the Royal Army Medical Corps, like that for the whole army, was launched in a hasty manner, without any preliminary consultation with those who could have given expert advice. Mr. Brodrick may be clever, alert, and determined, but he is only an amateur, and could not be expected to evolve a scheme of reform of a department whose duties he could not easily grasp. He has managed to increase the distrust of the authorities which his previous conduct had produced. Everywhere one hears only of dissatisfaction, and no wonder. Think of requiring an officer to be examined once more after eighteen years' service; and think of such a requirement affecting the right to retire on a pension. Further, remember that this examination is only the last of a series which is to dog the steps of the officer at every stage through all those eighteen years. These examinations alone are quite enough to deter young men from entering the service. Sir F. Treves ventured to defend them, and evidently thinks any surgeon should be able to pass them. But though he has achieved the position of an authority on some subjects, I venture to say there are questions in the domain of surgery about which he would not care to be examined, and, of course, as a civilian, even with his late experience in South Africa, he can hardly be supposed to be familiar with all the points affecting the work of the R. A. M. C.

The earlier examination stands on a different level, but the committee seem to have so muddled the scheme that we have different interpretations of its effects. One says, junior officers are to be kept at home for four years; another declares that they will go to India on leaving Aldershot, and after three years be examined there. But the scheme gives them six months at a hospital to prepare for the examination. This looks likely to lead to disorganization. How are all these officers, scattered as they must be throughout India, to be gathered for examination? Their stations could not be left unoccupied, and the cost of supplying their places while they are on study leave and being examined would be very great.

The proposed inspection of the military hospitals by the Advisory Board looks well enough on the surface to the mere civilian, but when we come to hear from officers of experience, what it would become, it appears likely to prove impracticable.

Altogether, I doubt if the scheme will, in the long run, improve Mr. Brodrick's reputation as a politician, all because he was so satisfied of his own ability to form it that he declined to consult expert opinion.

The Purvis Oration was founded by the West Kent Medical and Chirurgical Society in memory of its late Treasurer, Dr. Prior Purvis, a practitioner of sixty-six or sixty-seven years' standing, for he took his first qualification in 1834. He added the "M.B." of London in 1839, and the "M.D." in 1842. The oration this year was delivered by Dr. Goodhart, who has always something to say well worth listening to, and generally says it in a way both attractive and instructive. He began by remarking how happy must he be to whom it is given to look back upon the wealth of experience that sixty-seven years of practice must have brought, and what a pity it seems that Prior Purvis cannot deliver his own oration and unload himself for our benefit of his stores of knowledge. If that could be, Dr. Goodhart felt sure, he said, that one thing revealed would be that the practice of medicine all along is an original research; so he took this thought for his subject and dilated upon it in a delightful manner. "Only the other day," he remarked, "the President of the British Medical Association, no doubt with that modesty which so much becomes a great position, delivered practical medicine, bound hand and foot, and cast it into the chamber of death." That was his translation of the President's estimate of the biologist above the practitioner, the former being described as a high priest of the arcana of nature," the latter as not so, although "indispensable." But Dr. Goodhart, for the practical man, claimed no less than equality with the great biologists, and as to the "indispensability" saw no more in that than the privilege shared "in common with, say, the undertaker," and he went on [illegible] of nature. [illegible] that the only scientific worker is the man who spends laborious nights and days in a laboratory [illegible] that the practitioner [illegible] and [illegible] on the [illegible] and pay on the [illegible]."

The practical man [illegible] with the [illegible] of progress. [illegible] like Moses on Mount Pisgah showed that the promised land [illegible] with Willan [illegible] in England [illegible] with George [illegible] and other early pathologists [illegible] and Patrick Stewart, who [illegible] the P M [illegible] between typhus and typhoid.

To find the [illegible] of typhoid was [illegible] unless it [illegible] of the night [illegible] of epidemics also it is true [illegible] the night cometh when no man can work.

Other [illegible] mentioned were [illegible] Addison's [illegible] without the great [illegible] by the [illegible] Pasteur [illegible] the idea and Lister showed how it could be carried out safely.

From this Dr. Goodhart passed on to relate some of his own experiences in clinical work, and very suggestive all of them were.

The annual meeting of the Prince of Wales Hospital Fund, which on the first of the New Year will be named King Edward's Hospital Fund, was held on the 21st.

The Prince presided and made a speech expressing his own interest in the work. The financial statement was approved, which recommended a distribution of £50,000 among the hospitals, being £1,000 more than last year.

Considerable sums have already been subscribed in connection with the fund to form a coronation gift to the King.

Smallpox is still on the increase. The week opened with the largest number of notifications yet attained, viz., forty-one on Monday. Some cases have also occurred at other provincial localities—said to be generally taken by tramps. At midnight on Wednesday there were 590 cases under treatment, and yesterday twenty-seven fresh notifications were added.

Livingstone College was founded in memory of the great medical missionary. It was opened in 1899 for the training of medical missionaries. During the last term there were nineteen students in residence and nine others non-resident.

The Poplar and West Ham Hospitals have afforded facilities for clinical instruction to the students.

THE PRIVILEGES OF THE ACADEMY OF MEDICINE AND THE DUES QUESTION.

To the Editor of the Medical Record.

Dear Sir: In your issue of January 4, a "mortified listener" ventilates his grief at what occurred in a stated meeting of the New York Academy of Medicine a few weeks ago. Being anonymous the letter deserves no reply. But for the benefit of those who may have read it and are no better acquainted with the Academy than your correspondent, I copy from its by-laws as follows:

"VIII. The Treasurer shall report to the Council in February the names of all Fellows who are one year or more in arrears of dues.

"X. Sec. 12. The council shall . . . notify said delinquents by mail of their arrearages.

"Sec. 13. It shall within eight months thereafter report to the Academy the names of all Fellows so notified, whose dues remain unpaid."

That settles the question of the propriety of the reading of certain names before the stated meeting. No. XXIII of the by-laws militates directly against the gratuitous advice furnished by your correspondent, who wants special "executive sessions" of the Academy of Medicine for the reading of names. If he were a member of the Academy and saw fit to do so, he could use his "best" efforts—but not anonymously—to change all that.

To my anonymous "mortified moralist" "it seems not unduly [illegible]" (why [illegible] mercenary, Mr. Editor?) "for the members to [illegible] that a substantial distinction should be made between the privileges of members and non-members." The New York Academy of Medicine, however, has seen fit to follow a different policy. According to its constitution, "each candidate for resident fellowship must have been a graduate and licentiate in medicine in active practice, or have been engaged in scientific [illegible] for the three years preceding the application, and must be a resident of the State of New York."

Thus the [illegible] many of the younger members of the profession [illegible] on account of their age. That is why the spirit of [illegible] becoming a liberal profession has induced the Academy to admit them, and those whose [illegible] to the object of the Academy—"the promotion of the science and art of medicine, including the maintenance of a public library" (Constitution, Art. II)—to almost all the privileges of Fellows, and why national medical societies are given the free use of our halls without cost. This liberality [illegible] by your correspondent is widely appreciated and has largely contributed to the high esteem the Academy is held in all over the country, and even in New York City. The best proof is found in the large number of non-members who crowd the reading room. In connection with these facts I may be permitted to divulge an observation made during my forty-five years' membership and my seventeen years' [illegible]ship, viz., that those who pay up regularly as soon as the annual bill is presented in large majority express their delight at the [illegible] of [illegible] and at the general good our institution does, while [illegible] is [illegible] by [illegible] and [illegible].

To be a Fellow of the Academy is a high honor, both on account of the good it does and of the difficulty encountered before admission. That is why we cordially invite meritorious and ambitious young men to join. The careful sifting practised by the Committee on Admission makes it a select society and the acknowledged head center of the body politic of New York. This honor is appreciated by its Fellows, and I trust there will be no change in that sentiment. The majority of the Fellows do not want a "substantial distribution." They will always open their doors to their young colleagues and to such as are not yet prepared to pay for the facilities offered. The large number of persons utilizing them proves the policy of the Academy a glorious success.

Now, sir, when a man who can afford to pay twenty dollars a year for benefits offered to him and to his brethren refuses to contribute to the maintenance of the Academy and its library, and has the nerve of getting up in public and telling the Academy that he refuses his contribution on the ground that he prefers to take its services gratis—permitted to do so by the unwritten law of the Academy—I shall always believe him almost as bad as an anonymous aggressor, and shall always, as I did lately and in a similar instance a year ago, stand up and expose—not anonymously—the callousness of parasites. These men are welcome to retire from an institution to which they should never have belonged. With their lack of public spirit they do not fit into a liberal profession, but into some money-making or money-shaving trade.

A. Jacobi, M.D.

19 East Forty-seventh Street, New York.

To the Editor of the Medical Record.

Sir: If the Academy of Medicine needed a champion there would be forthcoming far abler pens than mine to engage the lists in her behalf; my object in addressing you is to reach and reason with your humiliated correspondent of January 4th, and others, "not a few who ask themselves in the privacy of their homes, whether the honor of being a member of the Academy is a satisfactory equivalent for the twenty dollars a year paid in dues."

It is the height of hospitality for a host to make the guest in his household his equal, and where, as in the case of the New York Academy of Medicine, the profession has a common meeting ground, it would become a great folly to permit of restrictions changing this great institution into a mere club-house. Members who fall short of understanding this policy of altruism of the Academy toward the general profession certainly have the right to resign, but be they few or great in numbers, the Academy cannot recede from its position as a public benefactor.

Frederic Griffith, M.D.

New York, January [illegible], 1902.

To the Editor of the Medical Record.

In the issue of the Medical Record of December 28th, last, there appeared a letter from a correspondent opening a subject which must have been food for thought for many who have not written about it, but who have felt none the less keenly that there was room for reform in the management of the Academy of Medicine. The members of that organization go on paying their dues and assisting in keeping up an expensive plant in the enjoyment of which they have no privileges not enjoyed by any one, lay or professional, except that of using the library in the evenings and of taking part in the debates. The former of these is hardly worth mentioning because practically any person can get a card for an evening in the library, and participation in an occasional debate seems hardly worth twenty dollars a year. The most self-satisfied trustee or other officer of the Academy would probably not have the hardihood to claim that under the present system, membership in the Academy carries with it any important honor or proves the possession of any great professional ability, since it is well-known that any graduate in medicine, in good standing within the meaning of the law, can easily get himself elected, provided he is willing to invest twenty dollars annually in the "honor," the material privileges of which can be enjoyed by any outsider. Many members will, no doubt, agree with me that they are not getting a fair return for their money, and most of us probably do not care to assist in supporting an expensive institution merely that large numbers of outsiders shall enjoy the use of an extensive library for which they contribute no support, and that a certain number of men shall enjoy the advantages which may accrue from being known as officers of the New York Academy of Medicine. Perhaps some sort of library subscription fee could be charged to those who wish to use the library, or who may be ineligible for election as regular members. Many members, especially the younger men, would undoubtedly welcome some sort of a restrictive rule by which the use of the Academy library and building should not be so freely extended to non-members, and by which the exclusiveness of a club should, to some extent, be enforced.

Apparently the only alternative to this which is fair is to reduce the dues and increase the membership to a great extent. Under the present régime there is a feeling of dissatisfaction which will break out from time to time.

A Dissatisfied Member.

TREATMENT OF DELIRIUM TREMENS.

To the Editor of the Medical Record:

Sir: Dr. Crother's most excellent article in a recent issue of the Medical Record, on the treatment of delirium tremens, contains many grains of truth and practical suggestions gained through years of experience. As one who has also had experience in the management of these cases, I must protest against the emphatic manner in which he excludes the use of nourishment in the initial stage of delirium. To withdraw the alcohol, thus lessening one source of toxæmia, is wise, but absolutely to prohibit food in one who is already physically weakened is taking away the only staff the system has to lean upon.

Many of these alcoholics have taken little or no food for days, frequently weeks, before the delirium manifests itself; further, to exhaust the physical condition only tends to prolong the convalescent period, and increases the difficulty in toning the patient. To say, "beef tea, milk, and all liquid foods are actually culture mediums for the production of toxins and the perpetuation of old ones," may be a witty solecism, but it is not borne out by fact. Eliminative processes should be pushed quickly to restore normal metabolism, but constructive metabolism must be a factor while excretion of toxins goes on, and "cell metabolism" is maintained rather than "deranged." Again, "restraint depends largely on the patient;" and that cerebral sedatives, to quiet and induce sleep, are "dangerous both in theory and practice." To this statement I also take exception. The writer has never yet observed a case but which derived benefit from sleep.

When the delirium borders on suicidal mania to escape hallucinatory persecution, sleep is the first essential. Far better to quiet, far better to sleep, than permit physical injury in a strong room (with the added danger of pneumonia by exposure) or at the hands of strong nurses. It has been said, "One who endeavors to quiet a delirium-tremens ward fattens a graveyard." Even at such a risk it is preferable to endeavor to restore an already shattered and disorganized brain by hypnotics, judiciously used, than assist in further debilitating the patient.

F. R. Searles, M.D.

Hampton Hall Sanatorium,
Springfield, Mass.

Exhibition at Glasgow.—Glasgow, says the *Sanitary Record*, is to be congratulated on the success of its International Exhibition, which closed its doors on November 9th. On that day, the attendance was a record one of 173,266, bringing the grand total for the six months up to 11,496,220. Financially, it is said, that the venture will benefit the city to the extent of £100,000 ($500,000)—a most welcome sum, considering the exceptional expenditure Glasgow has had to bear lately fighting both plague and smallpox.

Progress of Medical Science.

The Boston Medical and Surgical Journal, January 9, 1902.

A Case of Probable Dislocation of the Cervical Vertebra, with Spontaneous Replacement and Recovery.—J. E. Goldthwaite reports the case of a child of seven years who had received some injury while turning somersaults, which displaced the head to one side. Very little motion was possible, but the obstruction was evidently not muscular. A diagnosis was made of a partial dislocation of the cervical vertebra. The second day after admission to the hospital, just previous to the time appointed for taking an *x*-ray, in some movement of the head with a distinct slip, the normal condition was restored. After that the head could be moved almost normally in every direction with but little discomfort. It seemed probable that there had been a partial dislocation. Simple muscular strain or any other condition would hardly have been relieved with the suddenness that occurred in this case.

Unnoticed Fractures in Children.—F. J. Cotton states that the systematic use of the *x*-ray has confirmed the suspicion that fractures not infrequently exist with but slight symptoms, that mere cracks may readily be overlooked, that incomplete fractures or complete fractures without displacement are commoner than was formerly supposed, and may exist without being suspected by the patient. Eighteen cases are reported, ten of fracture of the clavicle, three of the bones of the forearm, two of the tibia, and three of a metatarsal bone, which illustrate the author's point, that we all tend to underestimate the tolerance of children to fractures. In small children, where there is a history of a fall or other trauma, and especially where the arm or shoulder girdle may be involved, the only safe way seems to be to assume a fracture as probable, till every inch of bone has been gone over carefully. Only in this way can we be safe from occasional oversights and from ignominious explanations later on.

Remarks on the Diagnosis Between Acute Appendicitis and Some Atypical Cases of Typhoid Fever.—Maurice H. Richardson says that when during an attack of typhoid fever a normal appendix is removed under the mistaken diagnosis of appendicitis, both patient and surgeon are indeed to be congratulated if recovery follows. Various cases are cited to show the frequent difficulty of diagnosis. The main point to be emphasized is that when local signs, especially tenderness and rigidity, are absent, fever strongly suggests typhoid. Without pain at some time during the course of the disease, there can be no acute surgical lesion of the abdomen; high temperature with pain, but without rigidity or tenderness, means typhoid fever, or simple continued fever; very high temperature should excite suspicion if pain and tenderness are present, but not marked, for acute appendicitis has usually a moderate temperature; a soft abdomen with a high temperature is a suspicious combination, even if there is pain and tenderness; when typhoid is suspected, the pain and tenderness must be distinctly localized in the appendix and confirmed by rigidity, resistance, or tumor, before operation for appendicitis is justifiable. When the abdominal symptoms call loudly for operation, the abdomen must be opened in spite of the possibilities of typhoid; but cases suggesting typhoid as strongly as appendicitis should, until the diagnosis is perfectly clear, be carefully observed.

Journal of the American Medical Association, Jan. 11, 1902.

The Influence of Some of the Commoner Drugs Upon the Gastric Functions.—Boardman Reed presents the following conclusions: (1) Perfectly normal stomachs are probably in the minority in large cities, especially among persons employed indoors. (2) In stomachs which are normal, or approximately so, the digestion may be injured by a simple bitter tonic, taken even for a short time. (3) Quite moderate doses of HCl, administered as a medicine, may prove effective in hypochlorhydria, but are likely to do harm to normal stomachs, and certain to aggravate hyperchlorhydria. (4) Pepsin rarely produces any good result when given alone, even to persons with weak digestive power, and often then retards the digestion of albuminoids. (5) Pepsin and HCl, given together, much more frequently do good than either administered singly.

Gastric Hyperæsthesia and Its Management.—C. G. Stockton defines this condition as one presenting painful sensations, not so intense as gastralgia, but causing more or less discomfort. The HCl is not above the normal—indeed, often below—yet it is apparently the HCl and the activity of the gastric digestion that cause the trouble. As a diet, it is best to select, in the beginning, one that is very bland; for instance, milk or some milk preparation. To this should be added, first, the digestible farinaceous foods, then eggs; finally, meat juice at certain meals, and later scraped meat, meat powder; and next, tender steak

[illegible]

Treatment of Chronic Myocarditis.—J. H. M[illegible] says that as regards the medicinal treatment, if we can settle upon a cause for the myocarditis or coronary artery disease, such as syphilis, this will indicate the course to be followed. Otherwise the arterial conditions must decide the question. With a low arterial tension, we should give digitalis, [illegible], strychnine, and other direct stimulants. If the tension is high, it is the custom to give remedies which lower blood pressure, and those who give such remedies see delightful results from nitroglycerin, [illegible] and other agents which lower blood pressure. The fact is too often overlooked that some general measures also reduce blood pressure, such as purgatives. Many of these cases are benefited by salines given early in the morning every day or two. There are cases of chronic myocarditis secondary to coronary artery disease where we cannot satisfy ourselves or determine by ordinary physical signs the exact state of the heart muscle, cases in which the condition may only be inferred from reduplication of the second sound of the heart and the state of the veins, where there is no dilatation of the heart walls. Nor, on the other hand, can we determine the existence of any hypertrophy, particularly that occurring with high arterial tension. There are cases of this kind in which the dyspnœa is marked with considerable arhythmia, in which we cannot obtain any special evidence from the condition of the vessels that would indicate high arterial tension. These form a class of cases in which digitalis will be of benefit. Other concomitant states requiring attention are angina pectoris, calling for the customary remedies, and dyspnœa. The latter occurs in two forms. In one case it is almost constant, increasing into paroxysms in times of special excitement or exercise. The second form is that which occurs only in paroxysms, in attacks which take the form of sudden œdema of the lungs, with chest oppression, and all the appearances of shock—pallor of surface, cold extremities, more or less anxiety, the expectoration of frothy material. Upon auscultation of the chest, the bronchial tubes are found filled with râles, and on auscultation of the heart the most interesting conditions are found—arhythmia and asystole. It is often impossible to recognize any murmur on account of the râles in the chest. These cases are frequently mistaken for pulmonary conditions. Such a case must be treated first as a case of shock. We must relieve the pulmonary œdema that has taken place, we must actively stimulate the heart and improve the circulation. Dry cupping of the chest and external hot applications bring the most speedy relief. There is no better remedy than morphine, administered hypodermically, in small doses for the relief of the patient. Together with strychnine and nitroglycerin, where there is apparently a condition of high arterial tension, where this is not present, morphine and strychnine alone will tide over the difficulty until the danger is past. Where there is venous stasis and lowered blood pressure the use of digitalis and ordinary stimulants will be sufficient to overcome the condition.

New York Medical Journal, January 11, 1902.

The Operative Treatment of Traumatic Intracranial Lesions.—Charles Phelps expresses the view that even a rational suspicion of the existence of a simple fracture, and in cases of hebetation with a history of considerable violence inflicted upon the head, with or without concurrent symptoms of intracranial lesion demands exploratory operation. He has frequently done this and when nothing beyond incision has proved necessary, has never failed of primary union. He presupposes recovery from immediate shock, a fair constitutional condition, aseptic precautions, and restriction of the wound to the limits required for its purpose.

The Plastic Use of the Uterus in Cystocele Operations.—Joseph Brettauer reports three cases in which the ideas of Freund and Wertheim were followed, the object being to fasten the uterus to the denuded anterior vaginal wall [illegible] bladder. It also serves as a support for the [illegible]. Brettauer thus describes the plan followed in his three cases. After the usual preparatory [illegible] through it. [illegible] The [illegible] surface of the uterus is now fastened with three interrupted [illegible] to the flaps of the anterior wall of the vagina about one-half inch from the edges. In the first case the flaps were not [illegible] with a [illegible] suture, and a [illegible] added in the usual way; in the second and third cases, the flaps were [illegible] after removing a strip of about one-quarter of an inch in width. The vagina was then packed with gauze and the patient put to bed.

Inflammation and Sclerosis.—C. L. K[illegible] calls attention to prevalent carelessness in the use of medical terms, stating that the ending "itis," as referring to inflammation, is applied to many conditions which are of noninflammatory. Inflammation, in the true surgical sense, refers to a condition following infection. Perhaps the word sclerosis is the right one for most of the instances of incorrect expression. Sclerosis is often confounded with inflammation, and while it is true that a long-continued infection or repeated infection leads to hypertrophy and subsequent atrophy, sclerosis [illegible] is the result of a long period of overwork. The viscera are particularly prone to the condition. Overeating is followed by sclerosis of the stomach wall; high tension of the circulatory and nervous systems gives rise to sclerosis of the heart, kidneys, and arteries. There is no infective process connected with these instances, yet we have in our nomenclature such names as "chronic interstitial nephritis" and "chronic myocarditis." The kidney is subject to acute disturbances of an infective or toxic nature, as in scarlet fever, and the condition is correctly named "acute nephritis." In the small, contracted kidney, however, is an atrophic change due to overwork or strain caused by high arterial tension and perhaps by extreme nervous tension. It is called "chronic interstitial nephritis," but there are no evidences of inflammatory action, and it is really a sclerosis of the kidney."

Medical News, January 11, 1902.

Bacteriological Diagnosis of Typhoid Fever.—Henry A. Higley speaks of the methods available in the bacteriological laboratory for the establishment of the existence of any disease produced by a given microorganism, as the following: (1) The isolation and identification of the microorganism producing the disease; (2) The application of certain staining reactions to the microorganisms, which reactions are peculiar to these microorganisms and differentiate them from all others; (3) The effect or reaction produced by certain body fluids of persons suffering from bacterial diseases when these fluids in certain dilution are brought into contact with microorganisms of the same species with which the person is infected, which microorganisms have been artificially cultivated in the laboratory—for example, the Widal reaction. This reaction will naturally be either absent or present. Its absence does not prove anything against a positive diagnosis. It may be present in cases which are clinically typical or atypical of typhoid. As to the staining method, no stain has as yet been discovered which is able to differentiate the typhoid bacillus from other organisms. The first method mentioned above is by far the most positive and absolute. The chances of an error in the isolation and cultivation of the microorganisms are reduced to a minimum. The author concludes by saying that there is no one method by means of which a man can sit down at the laboratory and with ease and positiveness make a diagnosis for or against typhoid fever in all cases. The resources of the laboratory must be combined with a careful clinical examination of the case.

Heart Strain; Its Result and Treatment.—J. M. G. [illegible] states that the study of heart strain is of comparatively recent date. The effect of heart strain is shown in two ways: (1) By overwhelming disturbance, causing immediate faintness, possible paralysis, and death. (2) A more gradual dilatation from lighter and daily strain. When the shock does not terminate in the death of the individual at once, the normal irritability of the heart is in a great measure lost. The heart muscles are in the condition of any other muscles which are unduly strained; the rhythmic action becomes feeble, tremulous, and imperfect. In the case of the heart the condition is one of profound asthenia. There are two periods of greatest danger—one is at night, during the hours when the periodic distress returns and when respiratory movements are most sluggish; the other is when, upon arising from a recumbent position, the column of blood in the upper part of the body is suddenly thrown back upon the enfeebled ventricles, thus diminishing brain pressure. Persons leading sedentary lives are more liable to heart strain than those in more active life. The treatment should be prophylactic, hygienic, dietetic, and medicinal. The first two classes include a well-ordered life free from all excesses. There should be freedom from all pressure over the heart from dress. All forms of food which have a tendency to form gas should be avoided. Complete digestion should be accomplished before taking a second meal into the stomach. Where the work of the heart is extreme, liquids should be limited. If blood-pressure is low, liquids should be administered. In cardiac asthenia with dilatation, a dry diet is indicated. Supper should be the lightest meal of the day. Before medicinal treatment is instituted, the cause should be removed if possible. In asthenia, digitalis and strychnine are the most important remedies. For hypertrophic over-action, aconite is useful; but caution should be observed. Valuable remedies for distress at night are belladonna, hyoscyamus, and cannabis indica.

American Medicine, January 11, 1902.

Dystocia Following Ventrofixation.—Fred. H. Bloomhardt reports three of these cases. In the first, just when operation—that of cæsarian section—had been deemed necessary, as the cervix could be felt only under anæsthesia, the breech was found to be presenting. The only explanation seemed to be that in the period between the two examinations, there had been a rupture of some of the adhesions, allowing the uterus to sink down in the pelvis. In the second case a Porro operation was performed. In the third case a Porro operation was also performed, but the mother died from exhaustion and shock.

A Plea for the More General Use of the Active Principles of Vegetable Drugs.—George E. Blackhan sums up the advantages of the active principles of drugs or their salts as follows: (1) Precision; being definite chemic compounds, their composition must always be the same and their action uniform. (2) Portability; being active principles, stripped of gum, coloring matter, and other extraneous matters, the dose is necessarily comparatively small, and a larger number of doses can be carried in the same space. (3) Safety; this is a result of their definite composition and uniform strength. (4) Effectiveness; the smaller dose is more readily absorbed, and therefore more quickly and certainly effective. (5) Palatability; this is perhaps a matter of minor importance, yet not to be disregarded. On account of the smallness of the dose it can be effectually concealed in a tiny granule which can be readily swallowed by the most fastidious.

Silver Wire Smoothly Brazed to the Butt of a Steel Needle a Convenient Suture for Certain Plastic Operations.—J. Rilus Eastman mentions some of the well-known difficulties in the use of the needle threaded with silver wire and describes his method of overcoming them as follows: In hare-lip and such operations, he uses a No. 24 standard-gauge silver-wire suture, eighteen inches in length, to one end of which is attached with silver solder, after annealing of both metals, a full or half-curved steel needle. In this way a perfectly smooth joint is formed, which will not unnecessarily injure delicate tissues. It has often been proved that metallic silver has an inhibitory effect on the growth of bacteria; silver wire is unirritating and strong, and it may be easily shotted. Silver wire is, however, perhaps not the most suitable material for buried sutures, for it is non-absorbable and may lead to sinus formation. However, the tolerance of tissues for this wire is greater than is generally supposed.

The Effects of Ventrofixation and of Ventral Suspension on Subsequent Pregnancy and Labor, with Report of a Case.—Arthur C. Jacobson reports a case in point in which labor was terminated by a medium forceps operation, as nature was incompetent to deliver. The writer states that the status of these operations has not yet been definitely determined. He gives some conclusions from his consideration of the subject. Apparently these operations reduce fertility. There is no special tendency to produce abortion. The greatest obstetric difficulty consists in the obstructing mass of tissue formed by the anterior uterine wall. Serious or insuperable obstruction to labor may be produced if the fundus and anterior wall of the uterus are imprisoned below the point of attachment between the uterus and the abdominal wall. According to Noble, the most serious difficulties could be obviated if labor were induced at the eighth month, if the anterior uterine wall constitutes a tumor at the brim. From an obstetric standpoint, ventrofixation may be considered as occupying an intermediate plane between vaginal fixation and ventral suspension. The writer concludes that pregnancy and labor are, as a rule, uncomplicated. Erroneous ideas should not be derived from the gravity of some of the reported cases. Excluding ventrofixation, the results of labor after suspensio uteri compare favorably with those under ordinary conditions. And although, when including ventrofixation, the results compare fairly well, still there are certainly some good obstetric reasons for distrusting the operation of ventrofixation in child-bearing women.

Philadelphia Medical Journal, January 11, 1902.

Duration of Immunity by Diphtheria Antitoxin.—Henry D. Jump concludes that: (1) As diphtheria antitoxin is practically harmless, all exposed persons should receive an immunizing dose in proportion to age; (2) Two hundred and fifty units should be given to children under two years and five hundred to all others; (3) The immunity will last for at least three weeks, provided a reliable antitoxin is used; (4) All exposed persons should be removed from infected surroundings, either by thorough disinfection of their own quarters or by removal to other places. If this is impossible, the immunizing doses must be repeated every third week.

Acquired Pulmonary Lues.—Otto Lerch reports this case. The patient was a man of forty-eight years, giving a definite history of syphilis twenty years before. His occupation was that of cotton sampler. The present trouble commenced with a tickling sensation in the throat. Dyspnœa became severe, the face wearing an expression of air-hunger. The arteries were pulsating. It was decided that there was no aneurysm from the absence of thrill and bruit over the dull areas in the chest, absence of characteristic pain in chest and back, absence of a downward displacement of the heart and of murmurs which would be probably found in a case in which aneurysm had long existed. There was no tracheal tugging. There were no symptoms of tuberculosis. The patient was a cigarette smoker. He was put on iodide of potassium and inunctions of mercury, and his improvement has continued from the beginning of the treatment, although it is not now so rapid as it was at first. The determining cause of this attack was probably the inhalation of dust and fibers which set up an inflammatory condition of the lungs. The prognosis, as in all cases of this disease, is grave as to recovery.

The Treatment of Inoperable Tumors.—Conrad George, Jr., considers the results of the use of pyoktanin, or methylene blue, and Coley's mixture in the case of certain inoperable tumors which have come under his observation. In the two cases treated by the first method, there was a marked diminution in the size of the tumor, with some relief from pressure symptoms, but there was an excessive stimulation to the growth of tumor cells in the neighborhood. It is extremely doubtful, says the writer, whether a cure could have been effected if the cases could have been placed under this treatment earlier in the course of the disease. He then describes two cases treated with Coley's mixture. The first was a case of granuloma of the right upper jaw, and although the tumor disappeared until there was only a very small amount of soft granulation tissue left on the outer side of the jaw, the tumor returned later and the upper jaw was removed. The second case was one of large spindle-cell sarcoma of the right fore-arm. The tumor continued to increase under the treatment. Two other cases which were treated by the same method showed no benefit. He concludes that his experience with Coley's mixture has been very unfavorable to its use in inoperable tumors.

The Lancet, December 28, 1901.

Tuberculosis of the Heart.—H. N. Heineman says that tuberculosis may affect the endocardium alone, the myocardium may be generalized in both or may involve the pericardium. The paper is largely a review of the literature of the general subject, and also contains the clinical histories of two cases of tuberculous pericardium. Directions are given for the staining of sections for microscopic examination. Concerning the general involvement of the muscle and endocardium, Heineman says that while the favorite seat in acute general miliary tuberculosis is the conus arteriosus of the right side, the great papillary muscle, and less frequently the endocardium of the ventricles, it is different in the small nodular form, which is not general, in which the ventricles are the favorite seat, and different again in the larger masses (caseous form), in which the auricles or the junction of auricles and ventricles and the ventricles (often near the septum) are the seat of predilection. As to the mode of infection, it is believed to be most commonly through the blood vessels. The large percentage of cases in which tuberculous nodules are found in the myocardium in connection with acute general miliary tuberculosis, and in which the blood vessels [illegible] the systems of digestion, [illegible] suggests [illegible] to refer the [illegible] in the less frequent cases. Again, the fact that the two cases occurred in different [illegible] or because in the one case we deal with [illegible], almost invisible, [illegible] is no argument against the probable identical nature of infection in all.

The Differential Diagnosis of Smallpox.—J. MacCombie says that in the diagnosis of this disease the following rules should be observed: (1) It should never be forgotten that the initial symptoms of smallpox are most constant both in vaccinated and unvaccinated subjects. (2) When called to a case the practitioner should never take for granted that the eruption on the trunk is like the eruption on the face and extremities, but in every case he should examine the whole eruption. Disregard of this precaution leads to many mistakes. (3) It should not be assumed that because a case of smallpox has occurred in a house therefore a vesicular eruption appearing on another inmate of the same house about the same time is smallpox. He has known cases of chickenpox and smallpox occurring simultaneously in the same house, and smallpox and enteric-fever cases in the same family at the same time. (4) It should be remembered that in a very large number of vaccinated subjects, smallpox is so mild that as soon as the eruption—consisting sometimes of not more than half a dozen spots—has appeared, the patient feels well. (5) Care should be taken to avoid ascribing the spots on the face in a mild case to digestive disturbances, and sending the patient to the seaside for a little change of air. The author passes in review the diagnostic points between the disease and erythema multiforme, typhus, influenza, ptomain poisoning, roetheln, drug rashes, varicella, measles, syphilis eruptions, herpes, impetigo, eczema, urticaria papulosa, acne, rheumatic sudamina, glanders, and pyæmic skin eruptions.

Some Points in the Prognosis of Mental Disturbance.—W. J. Haslett calls special attention to acute delirious mania, puerperal mania, insanity of adolescence, and melancholia. He says that the principal pros and cons of prognosis are the following. As the disease is not so acute, hallucinations are more serious, especially those of hearing. Imperfect bodily nutrition, such as loss of weight and trophic changes in hair and skin, the latter becoming earthy and greasy in appearance, are of ill omen. Degeneration of habits and inattention to the calls of nature, a constant desire to pick and rub the skin and pull out the hair are also of unfavorable augury. Certain delusions seem more liable to become fixed and permanent than others. For instance, visceral misinterpretations, such as the belief that the bowels never move properly, that the food does not enter the stomach, or that foreign substances are fixed in the body and require a surgical operation for removal, also delusions of persecution, plots, or unseen agency do not readily pass away. Again, sexual delusions, such as those respecting impotence, are of grave significance, and masturbation or fits are serious complications. The prognosis in climacteric melancholia is rendered very unfavorable by secret indulgence in alcohol or drugs, and he has noticed that the growth of facial hair in women has always been an indication that recovery will not take place. Prolonged suicidal promptings are of unfavorable import, and we must be on our guard in this respect, because the tendency often remains dormant for months, only to reappear when least expected. Adipose tissue and melancholia seem to be almost incompatibles, and an extra layer of fat is a very effective armor against a return of depression. Hence in treatment we do all that we can to encourage increased weight. An interest in her personal appearance is one of the primitive instincts of woman, and when we see her natural vanity re-awakening we begin to feel very hopeful.

The Lancet, January 4, 1902.

A Note on Three Cases Illustrating the Value of Suprarenal Extract.—The cases reported by W. H. Brown are (1) Profuse sweating following an attack of nephritis and cured by the remedy; (2) Bleeding in hemorrhoids; (3) Uterine hemorrhage from a myoma.

Beef-Worm in the Orbital Cavity.—T. W. F. Gann reports a case of this nature and gives an illustrated description of the worm. It is found especially in Central and South America. The native plan of treatment is to apply wet tobacco over the site of implantation and then to express the worm by pressure.

The Disappearance of the Addiment from Antimicrobic Sera.—E. W. Ainley Walker directs attention to the fact that the bacteriolytic power of a fresh serum rapidly diminishes both in the immune and in normal sera, and ceases to be recognizable within a few days from the time of bleeding. Hence it appears that as regards experiments in bacteriolysis the age of the serum which supplies the addiment is a factor of the first importance, and that observations on [illegible] addiment-containing serum cannot be properly compared unless they are performed at the same time, since the bacteriolytic action depends upon the variable factor above mentioned.

Etiology and Pathology of Scurvy.—G. Lamb gives the details of an outbreak of the disease occurring in one of the India prisons. He could not accept the theory that the disease was entirely due to dietetic errors, that is, to acid intoxication resulting from a deficiency in alkaline foodstuffs, for the following reasons: (1) There was no marked deficiency in the alkaline foodstuffs of the dietary before the onset of the symptoms. The diet was common to about 1,095 prisoners, and of these only six men developed scorbutic symptoms. (2) There was no diminution of the alkalinity of the blood serum observed when the symptoms were well marked. (3) There was no improvement in the symptoms either as a result of the giving of a diet consisting of abundant alkaline foodstuffs or on the administration of large doses of lactate of soda. Nor could the ptomain theory of causation be accepted because the patients had been receiving meat only once a week, and besides in India the animals are eaten the same day they are killed. Lamb therefore comes to the opinion that scorbutic symptoms, although associated in some cases with a condition of acid intoxication, in other cases develop quite independently of this condition. There would seem, in fact, more than one etiological factor and pathological condition underlying the symptoms which are clinically known as scurvy. He also suggests that scurvy symptoms may merely be an expression of ankylostomiasis.

Causes and Significance of Phantom Tumors.—Sir W. H. Bennett divides phantom tumors into three classes according to causation as follows: (1) Irritation: (a) Irritation of the skin or of other superficial parts either immediately over the muscle or muscles concerned or over the course of the nerves which supply them, (b) the existence of underlying disease or abnormality—for an example, supposing the tumor to be in the abdominal wall, some disease in the abdominal cavity which, by reason of its situation or relation, causes nerve irritation leading to contraction of a corresponding muscular area (such tumors, when occurring immediately over the underlying disease, are usually "protective"). (2) Occupation.—In a certain number of cases in which the occupation of the individual entails the use of a particular muscle or group of muscles for a long period continuously, the muscles concerned come, as it were, into permanent action, and remain hard and enlarged, although the occupation has been temporarily discontinued. These are "occupation" phantoms; (3) Imitation.—In a certain type of neurotic people the tendency to imitate the diseases or deformities of others is very strong. "Nervous mimicry of disease" was the admirable term applied to these cases by Sir James Paget. The nervous mimicry of hip-disease is, perhaps, one of the commonest examples with which we meet of this curious tendency. Tumors are sometimes imitated in the same way, although the scope for the deception is necessarily very limited. These are "imitative phantoms." Illustrative cases are described under each class. As to treatment the obvious indication is the removal of the cause.

British Medical Journal, December 28, 1901.

Direct Introduction of Purgatives into the Large Intestine in Cases of Operation for Septic Peritonitis.—A. Marmaduke Sheild describes this method. The nozzle of a small syringe is introduced into the "stump" of the appendix and the solution directly thrown into the cæcum. Three drachms of magnesium sulphate with 10 drops of tincture of nux vomica, and 1 drachm of glycerin in an ounce of water is the formula generally used by the writer. Two hours afterward a turpentine enema is given, and the result has been excellent.

Suicide by Incision of the Neck Posteriorly.—Henry Alston describes this case. The patient was dead when the writer examined him. There was an incised wound in the front of the neck opening into the pharynx, but the air passage was not touched, and the large vessels were intact. The wound in the back of the neck was 6½ inches long, almost on a level with the lowest edges of the lobes of the ears. It passed slightly into the spinal cord itself. Death was due to hemorrhage. Chronic ill-health was supposed to be the cause of the crime. The instrument used was a razor.

Theories of Inheritance.—G. Archdall Reid says that the main object of his paper is an endeavor to place heredity on a scientific basis. Heredity ought to be a science. The fact that offspring take origin not from the whole of the parent's body, but only from the microscopic germs, renders the transmission of acquirements exceedingly improbable. In no case has the transmission of an acquirement been proved. This line of argument is simple and conclusive, but it has been quite ignored. The writer believes that while inborn traits are transmissible, acquirements are not transmissible.

An Address on Localization in the Motor Cerebral Cortex.—C. S. Sherrington and A. S. F. Grünbaum have recently had the opportunity of making experiments on all the known species of anthropoid apes. In the chimpanzee the so-called motor area occupies unbrokenly the whole length of the precentral convolution, and in most places the greater part or the whole of its width. It extends into the depth of the Rolandic fissure. As to localization in the cortex, the sequence, broadly speaking, runs—tongue, mouth, nose, ear, eyelids, neck, hand, wrist, elbow, shoulder, chest, abdomen, hip, knee, ankle, toes, perineal muscles, anus, and vagina. As to the extent of the motor area, the writers think it probable that perhaps as much of that area lies hidden from the surface in the sulci as actually lies at the free surface on the convolutions. In the majority of the individuals upon which the writers have experimented, cortical epilepsy has been easily provoked.

British Medical Journal, January 4, 1902.

Carcinoma and Malaria.—John H. Spitzly believes from his experience in Dutch Guiana that there can be very little antagonism between malaria and carcinoma. He cites various instances in which patients who were thoroughly inoculated with malaria were afflicted with carcinoma or epithelioma.

Retrogression in Mammary Carcinoma.—James Pearse reports the case of recurrent cancer in a woman of forty-four years. The condition was so bad that the writer thought that she had only about three months to live. But then came a change. The first nodules have completely disappeared; the enlargement of glands is less marked; the aphonia has improved. Menstruation, which, before, had been regular, has ceased for several months. The writer adds that it would be hazardous to say that the abatement of the disease is to be associated with this fact.

Accidental Removal of Auricle by Midwifery Forceps, and Successful Application of Artificial Auricle.—James Erskine notes this case. The patient was a little boy whose ear at birth had been severed by forceps. No attempt had been made to suture the member in place. An artificial ear was made of Vela rubber vulcanized. It is kept in place mainly by the insertion of the process into the external meatus of which it is a cast. For the admission of air it is perforated right through. The application of seccotine is sufficient for the adhesion of the internal surface of the artificial auricle to the corresponding parts remaining.

A Clinical Lecture on Oophorectomy in the Treatment of Cancer of the Breast.—H. T. Butlin states that he does not know of a single case of cancer of the breast in which a patient can be claimed to have been cured by oophorectomy. When the disease comes back again, as it generally does within six months to a year, and sometimes more quickly, it does so exactly in the same form and with all the same troubles which were present at the time of the operation, and the patient grows slowly worse and dies. The manner of death and distress of it are not changed by the operation. A large number of women upon whom it has been performed, and who have been soaked in thyroid extract, have not received the smallest benefit in the world. It is true that this method has for the most part been used in very bad cases of cancer. The writer adds, however, that he has not the courage or the faith to use this method in cases where the cancer is very limited in extent, and where the lymphatic glands are not obviously affected. This would be the only way to prove the status of this method.

Berliner klinische Woehenschrift, December 23, 1901.

Symptomatology and Therapy of Cervical Ribs.—M. Borchardt says that the symptomatology of cervical ribs may be divided into (1) Local deformities; (2) Circulatory disturbances, and (3) Characteristic nervous appearances. The local signs consist in a marked fulness in the supraclavicular fossa and a visible pulsation of the subclavian artery; the latter, however, is not present when the abnormal rib is but slightly developed. The circulatory disturbances are dependent upon aneurysm or thrombosis of the subclavian artery or its branches, and consist principally of cyanosis of the affected extremity and a reduction in the force or absence (in extreme cases) of the radial pulse. The nervous disturbances are limited to the territory supplied by the brachial plexus, and consist of hyper- or hypo-æsthesias and paralyses. In the vast majority of cases, however, the presence of cervical ribs gives rise to no symptoms. This is because in most cases such ribs are not sufficiently developed to produce pressure upon the structures above mentioned. When subclavian aneurysms are present, operations for rectification of the deformity should be resorted to only when serious symptoms arise and life is endangered thereby. If nervous symptoms are present and electrical treatment is not followed by good results, operative procedures should be instituted before atrophy has taken place. In this class of cases uniformly good results are obtained thereby. This statement applies only to those instances in which the nervous disturbances are directly resultant from pressure upon the brachial plexus, and careful examination should always be made to ascertain whether or not such is the case. Four cases are reported which illustrate the application of the principles above laid down.

What Cases of So-called Surgical Tuberculosis Are Suitable for Climatic Treatment?—Dr. Sprengel reviews the statistics of the climatic treatment of surgical tuberculosis, and shows that so far as Germany is concerned all forms of surgical tuberculosis without discrimination and without regard for fundamental surgical principles have been treated in climatic sanatoria with extraordinarily poor results. When we consider the excellent results obtained by many, especially Cazin and Scheimpflug, in the exclusive utilization of operative procedures in the treatment of the surgical tuberculosis of children, it is very evident that on the whole surgical treatment is of much greater value than climatic. It seems probable, however, that the best results are to be obtained by a proper combination of both of these methods. To this end surgical tuberculous diseases should be classified as follows: (1) Those without deformities and which in all stages are surgically curable. Such include gland tuberculosis, the open and closed tuberculosis of the long bones, metacarpus, and phalanges, the open and closed tuberculosis of the knee joint in children and young adults, the open and closed tuberculosis of the ribs and sternum, and tuberculosis of the cranial bones. (2) Cases in which surgical treatment is followed by unsatisfactory results and marked deformity. Here we have closed spondylitis, closed tuberculosis of the hip joint in children, and closed tuberculosis of the joints of the upper extremity. (3) Cases which are only curable by operations which involve the removal of a large amount of tissue. Such are bone and joint tuberculosis of adults, the open forms of bone and joint tuberculosis in young adults, and genital tuberculosis. (4) Incurable cases, as hip-joint tuberculosis in persons over 25 years of age, open spondylitis, and the majority of the cases of multiple tuberculosis. According to this classification, in groups one and three the preference is to be given to surgical treatment. As soon as possible, however, after the operation the patient is to be placed under the proper climatic conditions, and should so remain until complete healing has taken place. In groups two and four, climatic measures are preferable, although ultimately a few cases may become suitable for operative interference. It is of course apparent that these rules cannot be indiscriminately followed, and that certain variations will be necessary in individual cases; but it is thought that their general application will be followed by much better results than have hitherto been obtained.

Symptomatology and Therapy of Chronic Pulmonary Distention or Inflation (Vagus Neurosis).—G. Zuelzer says that peripheral irritation of the vagus not only gives rise to true asthma, but in certain instances to a condition of which he treats under the above title. He describes two clinical forms. In both, the lungs are unduly distended and periodical attacks of moderate dyspnœa are present. In the first form, the heart is weakened and the pulse rate increased, while in the second form the pulse is markedly reduced in frequency, often as low as 42 to 64 beats per minute. It is the second form to which Zuelzer draws special attention. The patients are generally males from eighteen to forty-five years of age. They complain of vague uneasy sensations in the chest which are often burning in character. Slight dyspnœa is present, especially on exercise, but cough and expectoration are not observed. The general condition is fair. Various nervous symptoms may be present and there is usually great apprehension of tuberculosis or organic heart disease. Physical examination shows that the lungs are distended, the lower border being considerably depressed, and the area of cardiac dulness encroached upon. The power of pulmonary expansion is markedly reduced, as shown by the slight variation in the position of the lower border of the lungs in inspiration and expiration. Auscultation in simple cases gives normal vesicular breathing. The respiratory frequency during rest is normal or only slightly accelerated. No cardiac valvular lesions are present. Many facts go to show that peripheral vagus irritation is the fundamental factor in the causation of both of these classes of cases. Experimentation has shown that in animals whose vagi are irritated, the fibers of this nerve which supply the lung become exhausted before those which supply the heart.

[illegible] respond to the pressure and we get paroxysmal [illegible] of the heart as described in the second class of cases. The diagnosis of this disease rests upon the establishment of three facts: (1) The absence of [illegible]; (2) The establishment of the direct relation between the pulmonary and cardiac symptoms; (3) the demonstration that irritation of the vagus is responsible for the condition. This may be ascertained by direct pressure upon the vagus as it lies behind the posterior border of the sterno-cleidomastoid muscle. The treatment is the internal or subcutaneous administration of atropine. This drug here possesses a specific action. It should be given in daily doses of 1 to 1½ mgm. (gr. [illegible]), preferably by the mouth, as subcutaneous administration is not always well borne. Eight to ten days of this treatment generally suffice to bring about a complete cure.

French Journals.

Uterine Fibroma and Cancer.—Jacobs reports the case of a woman aged forty-eight years. Her family history was negative. She had suffered from metrorrhagia for several months. She had not menstruated for two or three years. She suffered intense and continuous suprapubic pain, vesical tenesmus, difficult and painful defecation. There was a continuous bloody discharge. She was emaciated. Abdominal palpation revealed a pelvic tumor, round and slightly movable. By vaginal touch the cervix was found to be enormous, greatly dilated, and bleeding at the slightest touch. The diagnosis lay between a polypoid fibroma and a cancer of the body. Laparotomy was performed, and disclosed a fibroma of the size of a child's head which had developed in the posterior uterine wall. The body mucosa was normal, but beginning with the internal orifice, the uterine tissue was in a state of carcinomatous degeneration. Here, then, is an example of the existence in the same organ of two neoplasms of different nature, fibroma and carcinoma, a benign and a malignant growth.—*Le Progrès Médical Belge*, January 1, 1902.

The Early Diagnosis of a Relapse in the Course of Typhoid Fever.—G. Lemoine speaks of the symptoms indicative of relapse in typhoid. During the course of the primary attack, there is to be noted constipation, anomalies of the rose spots, either an excess or want of them, the irregularities of the temperature curve and the predominance of adynamic symptoms. Signs during the period of defervescence are irregularities of temperature and the persistence of the intensity of the diazo-reaction. Signs in the period preceding the relapse are numerous, the leaden color of the face, an appetite greatly exaggerated in comparison with the temperature and the appearance of the tongue, the persistence of the enlargement of the spleen, the persistence or reappearance of the diazo-reaction of Ehrlich, the feebleness of the agglutinating power, and the absence of diuresis. The negative signs, first noted by Hanot, are hypothermia, slowing of the pulse, and polyuria. These mark the beginning of convalescence. The writer concludes by saying that if at the beginning of convalescence the persistence or reappearance of tachycardia, the disassociation of pulse and temperature, the persistence of enlarged spleen, and the absence of diuresis and hyperhidrosis are observed, he believes that there is sufficient ground for making the early diagnosis of relapse.—*Le Bulletin Médical*, January 4, 1902.

American Journal of the Medical Sciences, January, 1902.

Report of a Case of Dementia Præcox.—William Rush Huston, Jr., states that the majority of authors agree that this disease is a degenerative psychosis. He describes the case of a Norwegian woman thirty-one years of age, and sums up the symptoms of the case which he reports as follows: Mental depression, exaggerated tendon reflexes, a weakening of the heart's action, cyanosis, and a decrease of weight while taking nourishment well. Simple perception of external ideas was not interfered with, but there was fallacious sense perception. Negativism was present, but not very marked. Deterioration of the emotional life was shown by periods of depression and attacks of boisterousness. Stereotypy and verbigeration were shown on several occasions. Katatonic rigidity was present. This case seems to illustrate the katatonic form of dementia præcox.

Recent Views of the Origin and Nature of Herpes Zoster.—Albert Von Hartungen concludes that, under the term herpes zoster, is to be understood a specific infectious and possibly contagious [illegible] and pains of [illegible]. After this there are usually neuralgic pains along certain nerve paths, together with the development of enlarged lymphatic glands. After a few days the eruption appears. Rarely [illegible] complications develop. The infection attacks chiefly the posterior (sensory) ganglia of the cord and the Gasserian ganglion. The nature of the disease is not yet known. Zosteroid eruptions are often observed in cases of poisoning from coal gas, after the injection of arsenic, after injuries of the nerves or a spinal shock, and in many other conditions. These must be distinguished from the true herpes zoster.

Some Experiments on the Intermediary Circulation of the Bile Acids; A Contribution to Our Knowledge of Icterus.—[illegible], after careful study of this subject, believes that we are justified in assuming that aside from their extra-intestinal functions the bile acids are concerned in the normal destruction of worn-out red blood corpuscles, that they exercise an influence on the flow of bile, that they aid coagulation and play a rôle in vaso-dilatation; in pathological states, when large quantities of the bile acids enter the blood, their other powers are developed and become clinically manifest. All arguments that are based on their "presence" or "absence" from the blood are essentially fictitious and invalid. From the bile acid findings in any given case we are no longer justified in categorically asserting or denying the existence of pure hæmatogenous icterus, nor are we aided by these findings in formulating any definite diagnostic conclusions in regard to the participation of the liver or its ducts in any disease process complicated by icterus.

Cause of Death in Aneurysms of the Thoracic Aorta Which Do Not Rupture; Report of Five Cases.—H. D. Arnold divides these cases into three classes: (1) Cases in which an aneurysm of the arch of the aorta exists, but in which it is not the important factor in the fatal result. (2) Cases in which death ensued from disease or disturbance of the circulatory system not caused by direct pressure of the aneurysmal tumor. (3) Cases in which death was due, directly or indirectly, to pressure of the aneurysmal tumor upon organs of vital importance. In the first class are those cases which die from some intercurrent disease whose origin cannot properly be ascribed to the aneurysm. Class two includes those cases of death from circulatory disturbance not caused by direct pressure on the blood vessels. In these cases the chief doubt will arise in deciding what part arteriosclerosis, when it is associated, played in the fatal termination. Arteriosclerosis may cause death by the changes which it works in the nutrition of the vital organs, by rupture of the arteries affected, by thrombosis or embolism. As to the third class, pressure on the trachea or the primary bronchi frequently causes death in aneurysm of the arch. Sometimes pressure is exerted on the pulmonary tissue. The œsophagus may receive the brunt of the pressure, so that there is insufficient ingestion of food. A very rare cause of death results from pressure on the thoracic duct. This interferes with nutrition.

A Case of Chronic Lymphatic Leukæmia in an Infant.—J. Allison Scott reports this case of an Italian boy aged [illegible] months. When the child was one month old he was noticed to be unnaturally pale. Ever since that time he was subject to attacks of intestinal catarrh, with green stools containing much mucus. There was no evidence of rickets. When first examined the spleen was found to extend four inches below the costal margin. There was no marked enlargement of either the liver or the external lymphatic glands. The urine contained no albumin, but there was an excess of urates. Blood smears showed a marked poikilocytosis, with many microcytes and macrocytes, and a decided leucocytosis in which the lymphocytes were proportionally high. There was a considerable number of nucleated red cells (normoblasts). After the early winter months, the child grew worse. He had a [illegible] pallor, there was little emaciation, the abdomen was protuberant, the spleen hard and much enlarged. The edge of the liver was just palpable, but the superficial lymphatics were not enlarged. The child died a few days after the examination from asthenia. This case showed a typical picture of chronic splenomegaly, with a leucocytosis of a slowly increasing lymphatic type; there were [illegible] reds of all sizes and some degenerated cells, a few myelocytes, and death from asthenia. The writer cites two cases that came to autopsy in which there was no leukæmic infiltration of tissues. He is inclined to the view that splenic anæmia and pseudoleukæmia anæmia infantum have their proper place in the secondary anæmias.

Society Reports.

THE PRACTITIONERS' SOCIETY.

Regular Meeting, Held on Friday, December 6, 1901.

Joseph B. Bryant, M.D., President, in the Chair.

A Case of Splenic Anæmia.—Presented by Dr. Beverley Robinson. This case was shown to illustrate the brilliant results of a surgical operation for splenic anæmia. The patient was a schoolboy, of Russian birth, whose spleen was removed by Dr. Francis H. Markoe, at St. Luke's Hospital, on December 1, 1893, that is, over eight years ago. He was then fourteen years old. The cause of the enlarged spleen in this case was first thought to be malarial poisoning, but this was never proven, in spite of repeated blood examinations. Prior to the operation, all rational medication was tried without avail. Immediately preceding the operation, a blood examination made by Dr. T. T. Southworth gave the following results: Red cells, 4,604,000 per c.mm.; white cells, 3,125 per c.mm.; hæmoglobin, 77 per cent.; lymphocytes, 22 per cent.; large mononuclear leucocytes and transition forms, 6 per cent.; polynuclear leucocytes, 70 per cent.; eosinophile cells, 2 per cent. Summary: White cells reduced in number, with normal relations in the proportion of the different forms of white cells. Red cells fairly normal in number and structure, and some reduction in the percentage of hæmoglobin. Thirty days later (that is, one month after the operation), Dr. Southworth reported that the red cells had improved somewhat in number, color, and resistance. The white cells, which were below the normal count previous to the operation, had increased to 17,180 per c.mm., showing a leucocytosis. The eosinophiles had also increased to slightly beyond the normal limit.

On March 3, 1898, fifty-one months after the performance of splenectomy, a blood examination showed 4,560,000 red corpuscles, 9,000 leucocytes, and 90 per cent. of hæmoglobin. At the time of the operation, the boy's weight was ninety-five pounds. The operation itself was without accident, but on the day following it, and for several days subsequently, the patient had threatening attacks of œdema of the lungs, and during this period his life was apparently saved by frequently repeated doses of nitroglycerin. The patient is now a young man of twenty-three years, and is enjoying excellent health. His spleen is in the museum of the College of Physicians and Surgeons.

Dr. Robinson said the case illustrated the fact that, whatever the function of the spleen may be, it is not essential to life, health, and, he presumed, happiness.

A Case of Splenic Anæmia, Showing Marked Improvement Under Treatment was presented by Dr. J. W. Brannan as follows: "This case is presented partly because there has been some doubt as to the diagnosis, but mainly because of the improvement which has followed the use of remedies which often prove useless in cases of similar nature. Samuel West, in Allbutt's 'System of Medicine,' defines splenic anæmia as 'a form of profound anæmia, progressive in character, ending fatally, generally of no long duration, associated with great enlargement of the spleen, but without leucocytosis or enlarged glands.' This description fits our case, except that, up to the present time, progress has been steadily toward recovery, though the spleen remains of about the same size as when first observed.

"The patient is a schoolgirl, thirteen years of age. The family history is negative. The mother has given birth to eight healthy children, with one miscarriage. This child has shown no symptoms of syphilis, nor any tendency to hæmophilia. She has had the usual diseases of children, and at the age of four years had 'yellow jaundice,' with gastric disturbance and clay stools, and was said by a physician to have an enlarged liver. She recovered completely from this attack. She has had no other ailments, but has always been a pale and delicate child. During the past year the mother has noticed a moderate fulness in the epigastric region, and the patient has complained of pain and tenderness in the region of the liver. For several years she has had a tendency to epistaxis.

"The present illness began in June last, when she had a slight hemorrhage from the stomach. The blood was dark, clotted, and mixed with gastric contents. There were no other symptoms, and the patient was up and about the same day. In the latter part of July she vomited a large quantity of clotted blood, fully one quart in amount. Since then she has been very weak and ailing, and has remained in the house most of the time. In August her abdomen began to swell, and the face looked 'bloated,' and on September 3 she was brought to Bellevue Hospital.

"On admission, the patient appeared fairly well nourished, but was extremely pale, with a somewhat yellowish tinge to the skin. The features had a puffy, bloated look. The temperature was 101°; pulse, 128; respirations, 22. On physical examination, the lungs and heart were normal, except for a soft systolic murmur, heard most loudly in the pulmonary area. The abdomen was symmetrically distended, the umbilicus protuberant, and the veins prominent. There was some tenderness on palpation over the hepatic and splenic regions. The liver dulness began at the upper border of the fifth rib, and ended at the costal margin. The splenic dulness extended from the eighth to the eleventh rib. The lower border of the spleen could not be made out because of the abdominal distention, but there was marked resistance in the left hypochondriac and umbilical regions. A fluid wave was obtained, with movable flatness in both flanks. There was no enlargement of the glands anywhere in the body. The urine had a specific gravity of 1,013, was free from albumin, sugar, and casts, but contained only .7 per cent. of urea. Throughout the stay of the patient in the hospital, the urine has been very moderate in quantity, with low specific gravity, and a very small percentage of urea.

"Examination of the blood gave the following results: Hæmoglobin, 18 per cent.; red corpuscles, 1,640,000, and white cells, 4,000 to the cubic millimeter. There was no poikilocytosis. There were no hæmatoblasts, nor nucleated red cells. The differential count of the leucocytes was normal, except for a slight increase of the eosinophiles.

"The patient was at once put upon full doses of the syrup of the iodine of iron, Fowler's solution of arsenic, whiskey, and acetate of potassium. Saline rectal irrigations were also given daily. Under these measures, she soon began to improve. At the end of a week, the distention of the abdomen had decreased sufficiently to permit palpation of the abdominal organs. The borders of the spleen could be felt extending downward to about an inch below the level of the umbilicus and anteriorly to within two inches of the median line. Its surface was hard and smooth, and not tender to the touch. The edge of the liver was felt one-half inch below the costal margin. The ascites continued to diminish, and in two or three weeks more had disappeared. The child's condition steadily improved, and for the past two months she has been up and about the ward. The most marked gain has been shown by the blood count. On October 17, the hæmoglobin had increased to 45 per cent., and the red cells to 3,600,000. At this time bone-marrow was added to the medication. The last examination, made to-day, gives, hæmoglobin, 75 per cent.; and red cells, 4,350,000. It will be seen by the chart that the number of the red cells fell from 4,350,000 on November 4 to 3,600,000 on November 16. This was apparently due to a moderately severe epistaxis on the 13th. The hæmoglobin was unaffected by the hemorrhage. The temperature, which was elevated on admission, has remained constantly above normal, and [illegible] was [illegible] as high as 105.° At present the daily range is [illegible].

"In spite of the great improvement in the [illegible] condition, there has been no reduction in the size of the spleen. [illegible] With the disappearance of the [illegible] and the return of the [illegible] to its normal [illegible], this hypothesis was abandoned, and the diagnosis of [illegible] seemed to be warranted by all the features of the case."

Dr. [illegible] said that while we must recognize the existence of such a disease as splenic anæmia, the conditions present in many of these cases are probably due to some particular cause, although we may not be able to discover it. We do not know why they exist at all. We may have a large spleen and hemorrhages from the stomach and bowels, but the true cause of the condition can only be disclosed by a careful autopsy.

Dr. Robert Abbe said the surgical statistics of splenectomy in leukæmia showed a mortality of about 90 per cent., but in cases of enlarged spleen from other causes, even with leukæmia, the mortality was only about 20 per cent., and, according to a recent review of the subject, the normal leucocytosis is usually recovered within five months after operation.

Dr. Robinson said that in the case he had shown the primary effect of the operation was to produce an increased leucocytosis, but ultimately the constituents of the blood resumed their normal proportion.

The President, Dr. Bryant, said that in pseudoleukæmia the rate of recovery was not far from 23 or 24 per cent., so far as the operative outcome was concerned, and the restoration to health has been so very uniform and complete that an operation is regarded as the proper method of treatment. Of the leukæmia cases, however, scarcely 12 per cent. have recovered.

Operation for Old Posterior Dislocation of the Forearm.—Presented by Dr. Chas. McBurney: "This patient, who is seventeen years old, fell downstairs nine weeks before she came under my observation and injured her left elbow. The injury was regarded by those who had charge of the case as a fracture, and was treated as such, the arm being placed in the extended position with long anterior splints. When the patient was brought to me, it was quite evident that a posterior dislocation of the forearm existed, and the *x*-ray photograph confirmed this diagnosis, and proved the non-existence of fracture at any point. Very slight motion could be made at the elbow.

"On January 19, 1901, the patient was etherized, and vigorous efforts made to reduce the dislocation. This attempt failed completely, and I therefore did the following operation. An incision five inches long, parallel with the long axis of the arm, was made, the center of the incision crossing the internal condyle. All the soft parts down to the bones were divided, and all of the tissues posterior to the internal condyle, including the ulnar nerve, were pulled backward. The internal lateral ligament was separated from the condyle, the joint opened, the tissues in front of and behind the lower end of the humerus were loosened, and the greater sigmoid cavity of the olecranon was freed from new tissue. It was still found impossible to produce reduction. A similar, though shorter, incision was then made on the outer side of the elbow, and the soft parts and lateral ligament were freely separated. Complete reduction could now be made. The wounds were sutured, the arm was flexed to considerably less than a right angle, and immobilized with plaster-of-Paris.

"The dressing was changed for the first time on the seventh day. Complete healing of the wounds had occurred. Passive motion was made at first every other day, then every day, and finally several times daily. At the present time voluntary flexion, pronation, and supination are entirely complete and normal. Voluntary extension does not quite reach the straight line. The circumference of the upper arm and of the forearm is less than a quarter of an inch below that of the opposite limb.

"The dangers to be anticipated in old posterior dislocations at the elbow have been clearly pointed out by Dr. L. A. Stimson. They consist chiefly in the displacement of the [illegible] ligaments, which form firm and powerful attachments, in the filling of the greater sigmoid cavity with new tissue, and the formation of new tissue and bands at various points about the joint."

Dr. Abbe said that in the one or two instances where he had had to resort to operative interference in elbow dislocations, he found the cases very difficult to manipulate. He did not find it necessary, however, to make both an inner and an outer incision. Reduction was successfully accomplished through an outer incision.

A Case of Aneurysmal Dilatation of the Aorta.—Reported by Dr. Edward G. Janeway. The patient was a man, forty-six years old, who gave no positive history of specific trouble. In March last, while at an elevation of 4,[illegible] feet above the sea level, he had a severe fit of coughing. After an ascent of 2,[illegible] feet more he had repeated attacks of coughing; they were explosive in character, and so severe that at times they produced unconsciousness. He was obliged to return to a lower level, and his health remained comparatively good until August 12, when he began to complain of shortness of breath on exertion, the breathing was stridulous in character, and gradually increasing in difficulty. When Dr. Janeway first saw the patient this symptom was very pronounced. The right radial and brachial pulses could not be detected. There was no swelling of the veins of the neck. There was no pulsation, either visible or palpable, on the anterior chest wall, but there was a well-defined line of dulness extending from the base of the heart up to a little below the manubrium sterni, and both to right and left of sternum. When the patient was in the recumbent position, air entered the left upper lung with considerable difficulty. Upon one occasion a very faint murmur was heard at the right of the sternum, from the second rib to the sterno-clavicular junction. There was no tracheal tug. The fluoroscope showed a body of large size in the region outlined by the area of dulness. The diagnosis rested between aneurysm and tumor. In favor of the former was the absence of pulsation in the radial and brachial arteries on the right side, also the age of the patient and the faint pulsation of the tumor that could be detected with the fluoroscope. Against that diagnosis was the absence of a murmur and of any visible or palpable pulsation on the anterior chest wall.

The patient gradually died of exhaustion, and the autopsy showed an aneurysmal dilatation of the aorta, involving both the ascending and transverse arch, and pressing upon the trachea.

Prognosis; Its Therapeutic Value.—Dr. Henry F. Walker read a paper with this title (see page [illegible]).

Aneurysm of the Aorta Perforating Into the Superior Vena Cava.—Reported by Dr. Walter B. James. The patient was a man, fifty years of age, a mason. He had always enjoyed absolutely good health until three months ago. At that time he began to suffer from slight shortness of breath on exertion, a moderate dry cough, and a little pain beneath the sternum. These symptoms have gradually increased somewhat in severity.

Two weeks ago, on waking in the morning, these symptoms were more marked, and there was moderate cyanosis of the face. Four days later the pain in the face became worse, and the face and neck and arms rapidly became enormously swollen. The dyspnœa was worse, and he was unable to lie down.

When he first came under observation, there was well-marked dyspnœa. The face, neck, and upper extremities were enormously swollen and deeply cyanosed, being of a purple color; this was especially marked in the ears. There was slight œdema of the lower part of the body, the legs, and the genitals.

The apex impulse of the heart was displaced one and three-quarter inches to the left of its normal position; the left limit of dulness corresponds to this point. The pulse was rapid, regular, feeble. In the first and second intercostal spaces at the right border of the sternum, there was a heaving impulse and a systolic thrill. Over this area was heard a peculiar and very unusual murmur. It was loud, high-pitched, of rather musical quality, suggesting that of a venous hum. It is absolutely continuous, there being no intermission at any time. The intensity varies markedly, however, being greatest during systole, and least during diastole. The murmur is not transmitted in any direction more than two inches from the point of its maximum intensity. There were physical signs of double hydrothorax.

The above symptoms and physical signs continued, the cyanosis and œdema of the upper extremities gradually becoming more and more marked. The patient's condition grew worse, and nineteen days after he was first seen he died of exhaustion.

Dr. James said that he believed that in spite of the fact that no autopsy was obtained, that it was possible in this case to make an absolute diagnosis of an aneurysm of the artery of the aorta perforating into the superior cava, the striking symptoms that have been detailed allowing of no other conclusion.

A number of similar cases have been reported by Stengl, Pepper, and others.

The physical signs pointed positively to aneurysm of the arch of the aorta, the cyanosis and continuous murmur pointed to an obstruction of the superior cava. This could only have been brought about by pressure of a distended aneurysmal sac or a thrombosis of the vessel, or a perforation of the aneurysm into the vessel. The suddenness of the onset of the symptoms, the great intensity of the murmur, and the fact that the patient lived nineteen days, all make it seem certain that it was a case of perforation.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, December 11, 1901.

EDWARD K. DUNHAM, M.D., PRESIDENT.

Primary Carcinoma of the Liver.—Dr. L. T. LEWALD presented this specimen which had been taken from an alcoholic subject. Since July, 1900, the man had had attacks of jaundice at intervals of two or three months, and lasting two weeks at a time. The attack of jaundice which had come on in July had persisted. On admission to hospital in September he was still markedly jaundiced and was suffering from diarrhœa and vomiting. The abdomen was distended and tympanitic, and there was a marked prominence in the right hypochondriac region. The area of liver dulness on the right side extended from the fourth interspace to three fingers' breadth below the free border of the ribs. The surface of the liver was very hard. The man died about three weeks after coming to hospital. At the autopsy, there were marked jaundice and emaciation. The liver was enormously enlarged, and practically the whole of its right lobe was occupied by a whitish mass, dense near the periphery and soft and necrotic near the center. The gall-bladder was not distended, and was involved in the growth. The excessive weight and size of the liver had apparently caused an excessive growth of the duodenum. It was thought the jaundice had been largely due to the pressure of the liver on the bile ducts as they entered the duodenum. The kidney showed parenchymatous degeneration and very marked bile staining. There were some old scars noticed at the autopsy over the anterior surface of the tibia. The gross appearance of the growth in the liver was that of a carcinoma, but microscopical examination showed it to be made up of fibrous tissue and compressed liver tissue. The diagnosis was somewhat in doubt, for the microscopical appearance was not typical of carcinoma. If the growth were smaller, it might be taken for a gumma Sections were exhibited under the microscope.

Thrombosis of the Pulmonary Artery.—Dr. LEWALD presented a specimen of thrombosis of the pulmonary artery. This artery, as well as the aorta, showed well-marked patches of endarteritis. The thrombosis was a large one, and formed in a branch leading to the lower lobe, thus shutting off the blood supply to nearly all of this lobe. At the time of the autopsy this lobe was the seat of extensive hemorrhagic infarctions. There was also a thrombus in the left ventricle of the heart. The case was interesting because of the occurrence of thrombosis in the two blood systems.

Dr. F. C. WOOD said that in three cases of primary carcinoma of the liver that he had seen, the growth in both instances had been very soft and friable, and the edges hardly distinguishable from the rest of the liver substance. Under the microscope the tumor cells contained irregular mitotic figures, and giant cells were very abundant. The cells quite closely resembled those of the liver.

Dr. WARREN COLEMAN asked if there was any evidence of dilatation of the right heart in the last case.

Dr. LeWald replied that the right side of the heart showed no marked change, although there was some hypertrophy of the wall of the right ventricle, and moderate mitral stenosis was present.

A Case of Phlegmonous Gastritis.—Dr. GEORGE P. BIGGS presented the following report of this case:

History on Admission to New York Hospital.—C. E., forty-two years old, German, female, tailoress. Always in good health. Menstruation ceased five months ago, but for the past three weeks the patient has been flowing most of the time. No history pointing to an abortion.

She was taken sick eight days before admission, and has been in bed ever since. The chief symptom was vomiting, which, however, was not very frequent the last few days before admission. The sickness began with a chill, followed by fever and pains all over the body, which later became limited to the epigastric region. From a physician who saw her twice prior to admission it was learned that her temperature had been 100° F., respirations 20, and pulse 90; that she was slightly jaundiced, vomited frequently, and that her bowels were loose. Abdominal pain has been cramp-like and intermittent.

The following notes were made at time of entrance into the hospital: Anxious expression; respirations rapid; thighs flexed; tongue dry, coated and fissured; breath fœtid; abdomen markedly distended and tympanitic; tenderness in epigastric, umbilical, and right hypochondriac regions; temperature 100 2-5° F., respirations 44, pulse 144; urine, 1,013, acid, reddish yellow, turbid, fair amount albumen, no sugar, uric acid, crystals, granular casts. High enemata ineffectual. Condition too critical to warrant operation. She died the following morning, temperature in the meantime having risen to 102 3-5°.

Autopsy.—Body well nourished. Rigor mortis marked. Abdomen distended and tense. Peritoneal cavity contained 1,000 c.c. of moderately thick yellow pus, without distinct fibrinous element. The pus was very generally distributed, though rather more abundant in the upper portion of the abdominal cavity. There was no offensive odor to the pus and no gas was present. The stomach measured 25x11 cm., and contained a small amount of bile-stained fluid. It was of yellowish color, covered with pus, and showed a few distinct foci of pus 1 to 2 mm. in diameter, just beneath the peritoneum. Purulent infiltration had caused great thickening of the wall every-

[illegible], except in a narrow strip 4 cm. in width, along the greater curvature at its cardiac [illegible].

In the infiltrated parts the wall measured ¾ to 1½ cm. in thickness, the greatest thickening being in the pyloric portion, where the submucous coat alone was ¾ cm. in thickness. The mucous membrane was slightly thickened, congested, and in many parts hemorrhagic. Over the anterior wall of the pylorus it was completely destroyed over an area measuring 1 by ½ cm., the base of the ulcer being formed by thickened submucosa. A larger ulcer, also in the anterior wall of the stomach about 2½ cm. from the pylorus, was of similar appearance, but irregular in outline. Its main part measured 3 cm. vertically and ¾ cm. transversely, and a branch extending from it at a right angle toward the pylorus measured ¾ x ½ cm. The mucous membrane near the ulcers and forming their borders was purulent, suggesting that the ulceration was secondary to the purulent infiltration of the submucosa. The pus from the peritoneal cavity contained myriads of streptococci, and the same organisms were obtained in pure growth from it.

Spleen was twice its normal size, congested, and soft.

Kidneys showed a moderate degree of acute diffuse nephritis and slight chronic interstitial nephritis. Lungs were much congested and œdematous. Uterus was moderately enlarged, wall thick and firm, endometrium roughened and cavity contained a small amount of clotted blood. Microscopical examination showed a chronic endometritis. All other organs were normal except for parenchymatous changes incidental to any infectious process. So far as could be determined the infection of the stomach was primary.

Syphilitic Stenosis of Bronchi.—Dr. Biggs also reported this case, and presented the specimen. The latter had been taken from a woman, thirty-five years of age, who, according to the history, had been well up to the night preceding her admission. At that time she had been seized with what was said to have been an attack of asthma. When admitted to the hospital the dyspnœa was of a peculiar type, being entirely inspiratory and suggesting laryngeal stenosis. The larynx was normal, and it was assumed that the dyspnœa was due to the pressure of a thoracic aneurysm. Because of the high temperature pneumonia had been suspected, but the physical examination was inconclusive. The patient died the following day. At autopsy, the trachea was found thickened and slightly flattened laterally. The bronchi generally on the right side were thickened to a marked degree, and there was such stenosis of the main branch going to the lower lobe that it would admit a probe only 2½ mm. in diameter in its first centimeter. Beyond this region it was dilated again to a diameter of 1 cm. The left primary bronchus also was thickened and in its first centimeter was so stenosed as to admit a probe only 1½ mm. in diameter. The balance of this primary bronchus was dilated to a diameter of 1½ cm. The smaller bronchi of the left side were not materially altered. These marked stenoses explained the dyspnœa and the absence of the usual signs of consolidation. There was lobar pneumonia of the whole right middle lobe, the anterior half of the left lower lobe, and a small portion of the left upper lobe. The liver was moderately enlarged and contained much amyloid material. Though not greatly enlarged, the spleen presented the typical "sago" type of amyloid deposit. There was marked chronic diffuse nephritis, but no distinct amyloid reaction was obtained. The aorta showed extreme chronic arteritis with slight calcification.

In addition to the peculiar appearances of the lesion itself, the syphilitic character of the bronchial stenosis was thought to be clearly indicated by the amyloid deposits and chronic arteritis.

Request was made for expression of opinion as to the explanation of the marked dilatation of the bronchi beyond the seat of obstruction.

Dr. T. C. Janeway asked if there had been a very large accumulation of secretion back of the stenosis, as he had seen such a condition in connection with dilatation of the bronchi.

Dr. Biggs said that there had been no accumulation of secretion back of the stenosis.

Dr. James Ewing thought that the dilatation back of the constriction could be explained on mechanical principles. As the air gradually made its way through the constriction, the pressure under which it entered the cavity would be limited by the suction force of inspiration. In reality the pressure of the air in the bronchi during expiration would be greater than during inspiration, and this might lead to dilatation of the bronchus beyond the point of constriction. The blocking of the constriction by mucus would tend to still further increase the pressure by obstructing the outflow of air.

A Case of Biliary and Pancreatic Stasis Due to Atresia of the Papilla.—Dr. A. E. Thayer reported this case. The patient was a man who several years ago had been taken ill with loss of flesh and strength and vomiting of blood. At that time he had been treated at Bellevue Hospital by some surgical procedure, the nature of which could not be determined. He had lived in apparent health for three or four years, and had then re-entered the hospital three months ago with jaundice. He was emaciating rapidly. The stools were typically acholic. There was a temperature of from 100° to 101° F. in the afternoon, with occasional higher degrees. The blood count showed leucocytosis of 18,000. Under the free border of the ribs was a large, fluctuating gall-bladder. This was aspirated, and about one pint of thin, clear fluid withdrawn. A suspicion of malignant disease of the liver or bile ducts had arisen, and an exploratory incision had been made, but the patient had died shortly afterward. The anterior thin margin of the liver showed some recent extravasation of blood and lymph. The liver showed a marked increase of fibrous tissue confined almost wholly to the distribution of the biliary passages. There was, however, no disseminated cirrhosis. The common bile duct and its main branches, and the pancreatic duct were enormously dilated, and the cystic duct was moderately dilated. On gross examination there was also a well-marked interstitial pancreatitis and interstitial fibrosis in the heart and kidneys. Microscopically the pancreas showed marked dilatation of its ducts, some bile staining, and a very well developed interstitial pancreatitis with atrophy of the parenchyma, the islands of Langerhans having been almost entirely spared. In the middle portions of some hepatic acini there were deeply pigmented cells. Many of the small biliary radicles were plugged with polynuclear leucocytes, a fact which agreed with the clinical symptoms of fever and leucocytosis. The papilla of the duodenum had been converted into a tough mass without any lumen. The gall-bladder had been found at autopsy filled with a recent clot, probably the result of the puncture of the aspirating needle. The case was of interest because of its bearing on the etiology of biliary cirrhosis. If biliary cirrhosis (Charcot-Hanot) arises from irritants conveyed through the biliary passages, why was it not present in this case? A most marked proliferation had occurred about the bile passages, but in the tissue between there was no "unilobular" or "unicellular" cirrhosis. Another aspect of the case was bile staining in some of the pancreatic cells adjacent to the dilated ducts, which is of interest in relation to interstitial pancreatitis, experimental injection of bile into the duct of Wirsung being a cause of this lesion in animals. There was no evidence of duodenal ulcer or of duodenal hemorrhage.

Specimen Showing Result of a Gastro-Enterostomy for Carcinoma of the Pylorus.—Dr. Thayer exhibited this specimen. The operation of gastro-enterostomy had been performed one year ago with the aid of a Murphy button. Since then the man had been able to eat freely, and had done well. At the post mortem the pylorus was found absolutely without lumen, while just back of it was the artificial opening formed at the operation, leading into the jejunum about half a meter from its upper end.

Sections from a Case of Dermatitis Exfoliativa.—Dr. Thayer presented sections from this case. He said that no clinical history had been obtainable; only a diagnosis of pulmonary tuberculosis and of dermatitis exfoliativa in a woman of thirty. Most cases have been observed in adult males. At the autopsy, there were some scattered submucous hemorrhages in the stomach. The colon showed tubercular ulcers, and the mesenteric nodes were enlarged and caseous. There was also atresia of the vagina. On microscopical examination, the kidney showed some chronic parenchymatous degeneration without much interstitial change. The spleen showed marked interstitial increase and proliferation of the endothelia in the small vessels. The liver showed fatty infiltration of the peripheries of the acini and young connective tissue about the vessels. The mucosa of the stomach was œdematous and the outer epithelia degenerated. In the mesenteric nodes many giant cells were found. The lungs were the seat of chronic tubercular and recent lobar pneumonia. In the adrenals the nuclei of the cortex showed hyperchromatosis, and the epithelia of the medulla were deeply pigmented. There was a well-marked corneous desquamation of the upper layers of the skin. The supra-papillary layers were very thin in some places and absent in others. The lymph spaces were dilated, and there was a proliferation of the epithelia in the sweat glands. There was a recent round-cell infiltration about the cutaneous blood vessels. In the outer portion of nearly every papilla there were from one to half-a-dozen large chromatophores containing yellow-brown pigment in coarse granules. The sciatic nerve and the breasts were the seat of fibrous hyperplasia. In other words, there was connective-tissue increase in kidneys, spleen, liver, lungs, breast, sciatic, and skin. This skin lesion might be a part of a general fibrosis, the result of the circulation in the blood of the toxins of tuberculosis. The coincidence of dermatitis exfoliativa and tuberculosis of the viscera had been noted in many cases.

Dr. C. A. Herter said that he had seen the patient from whom this liver had been taken along with Dr. Draper, in whose hospital service the case had occurred. According to his recollection, the man stated that he had not been jaundiced at the first attack. He had suffered from gastric symptoms, which had finally culminated in hemorrhages from the stomach. These had been the only striking symptoms. The patient stated that after an operation done at Bellevue Hospital he had been greatly relieved. He had gained in weight and strength rapidly, and the pain had left him. He had remained well up to three months before admission, when he had begun to suffer from sharp lancinating pains in the right hypochondriac region, and had become jaundiced. During the last month of his illness the jaundice had become very deep. It had been very difficult to say whether there was any relation between the first seizure and the final illness, but his own feeling had been that it could hardly be a malignant disease if the process had extended over all this time. There was a history of syphilitic infection eight years before. It had been thought not unlikely that there had been gallstones, and that the operation had been done for the relief of this condition. The condition seemed to him one of unusual interest, because the changes in the liver and pancreas seemed to be due to the atresic condition of the papilla. He regretted that the urine had not been examined for sugar, for injury of the pancreas was apt to be associated with glycosuria. Where there was slight jaundice and slight temporary glycosuria, it was probable that the pancreas had been injured.

Dr. T. C. Janeway said that he had seen several cases bearing on this point. In one case of catarrhal jaundice, after four weeks, sugar had appeared, and had persisted until sugar, but not starch, had been eliminated from the diet. Since the disappearance of the jaundice the glycosuria had not returned, no matter what the diet. In another case, that of a man who had been troubled with gallstones ten years previously, and who had more recently had frequent attacks of chills, fever, and sweating with emaciation, examination of the blood had failed to show the malarial plasmodium, but had revealed a leucocytosis. There was slight jaundice, and the urine contained 4½ per cent. sugar. In two months the sugar had disappeared from the urine, except after errors in diet, and the jaundice and fever had also disappeared. These cases, he thought, pointed strongly to some subinfection of the pancreas associated with stoppage of the bile duct. The case reported by Dr. Thayer suggested to him the possibility of there having been a duodenal ulcer, with a profuse duodenal hemorrhage, at the time of the man's earlier illness.

A New Animal Holder.—Dr. Robert J. Wilson demonstrated an animal holder he had been using for the last five years that can be used without the aid of an assistant, and which is so easily constructed that it can be made by any good laboratory attendant. It consists of a box with a sliding lid. The lid having a slit in the anterior end that engages the head of the animal, and on its under side a dam, which represents the posterior wall of the box and prevents the animal from backing out. The lid has on its posterior end two small slits just large enough to accommodate single links of small dog chains, which are used for holding the animals' legs in abdominal operations.

For operations about the head or ear-vein inoculations, the lid having been previously removed, the animal is placed in the box, the lid is slipped in, the slit in its forward end catching the animal's neck while at the same time the buttock dam on the under side of the lid pushes the animal's chest up against the anterior wall of the box, where it is held firmly and practically immovable in place without being tied in any way or made to suffer by restricting strings.

In securing the animal for abdominal operations, it is allowed to stand on the table or the floor, the lid of the box is held above its neck with the buttock dam pointing in the same direction as the animal's head. The lid is then lowered so that the slit in its anterior end embraces the animal's neck. The animal is then grasped firmly by its hind legs and drawn up so that it lies with its back on the board, with its hind legs completely extended.

These are secured in place by two small dog chains which are fastened about the legs just above the knees by slipping loops, and secured to the lid by having the links of the chains held in the slits at the posterior end of the lid provided for that purpose. The lid is then slipped into place with the animal's head in the box, and body lying exposed on the top. The small dog chains are particularly desirable, because they do not constrict and hurt the animal, and they do not require knots of any kind.

The following dimensions are for rabbits of 1,500 grams weight, but the holders can be made suitable for almost any sized animal.

Box.—Inside dimensions, length 14½ inches, heights of side walls, 4¼ inches; height of front wall, 3¼ inches. The front wall is also 2 inches thick. The posterior wall is represented by the buttock dam on the lid. *The Dimensions of Lid.*—Length 28 inches, width 4 inches, thickness ½ inch. Slit in anterior end of lid is 4¼ inches long, 1½ inches wide at its anterior end, and ¾ inch wide at posterior end. The buttock dam is fastened to the under side of the lid 10½ inches from its anterior end, and is 3½ inches long, 2¾ inches wide, and ¾ inch thick. The dog chain links should not be more than ⅜ inch long, and of the open-link variety.

Observations on the Iso-Agglutinating Action of Human Blood Serum.—Dr. C. A. Herter briefly described this reaction. He defined iso-agglutination as the close clumping or agglutination of human red cells by serum from another human being. Two [illegible] of the person to be tested are mixed with [illegible] cells separated by means of a centrifuge. When the serum of a normal or of a pathological individual is mixed with the cells of the same individual in the proportions named, or other proportions, this will show no agglutination and no [illegible] of [illegible] cells. When an agglutinating serum is brought in contact with cells of another human individual, this reaction takes [illegible] from five to [illegible] minutes. The [illegible] red cells [illegible] blood with [illegible] of the [illegible] of the [illegible] phenomenon, when the [illegible] from side to side of a watch glass. Instead of remaining homogeneous, the mixture [illegible] small [illegible] in which [illegible] [illegible] is [illegible] and [illegible] it is seen that the cells are separated from the serum in the form of a comparatively coarse, mottled mixture. The red cells are found to be closely packed together in large masses, and to have lost their rouleaux form. The red cells appear to have undergone a change in consistence, rendering them more plastic than normal, as shown by the distortion of cells which have been subjected to the pressure of the cover glass. The reaction can be observed with the unaided eye, when the test is made on a watch glass or cover glass. Dr. Herter said that this gross phenomenon was new to him, and he had been unable to find any description of it. The reaction had been obtained in nearly one-third of all the cases in the hospital in which the blood had been subjected to this test. Notes of twelve cases were read. Most of these patients were alcoholic. It had been found possible to expose the serum to a temperature of 56° F., for one hour, without affecting the reaction in the least. In two instances he had exposed the serum to a temperature of 60° F., in one case for half an hour, and in the other for one hour; and while the serum did not give the reaction so strongly as before, it was still very distinct. Ordinarily human serum is capable of agglutinating normally the red blood cells of the dog and rabbit. There is no relation between this reaction and the hæmolytic action of serum. It had not yet been determined whether or not an intermediary body is necessary for the production of this reaction. He was not yet prepared to say anything concerning the clinical significance of this phenomenon.

Dr. T. C. Janeway asked whether the serum from these cases agglutinates the red cells of the other patients, giving the same reaction with the normal red cells, also, whether the serum from a normal person not giving the reaction would agglutinate red cells from these patients—in other words, was there a mutual reaction?

Dr. Herter replied in the affirmative.

Dr. Ewing said that this contribution reminded him of some remarks made by Richardson of Boston on the interaction of specimens of normal human blood on one another and on the typhoid bacillus. Richardson had found that in some cases of typhoid fever not giving the Widal reaction, if some normal blood were added, the Widal reaction would be at once obtained. Richardson had found that when the typhoid serum and the normal serum were mixed in a certain order a complete reaction was obtained; but that the reaction was not obtained at all when a different order was observed. The subject was entirely new to him, and deserved careful study. He would personally be interested in studying the morphology of the red cells in connection with this reaction. It seemed possible that the [illegible] the so-called fatty envelope.

Blood Slides from Two Cases of Pernicious Malarial Fever.—Dr. Charles Bolduan presented these slides with a brief clinical history. One case was of the algid type, and the other of the comatose variety. The first patient was twenty-two years of age, had come from Cuba, and had not been ill previously. Five days before coming under observation he had felt chilly, had had muscular pains, and had vomited some black material. There had been no chills, and the stools were negative. Physical examination showed an enlargement of the spleen and no [illegible] symptoms. The temperature showed the [illegible] type, [illegible]. Examination of the blood showed a large number of signet rings. On the fourth day the patient had [illegible] and [illegible] to go home. A few hours later the pulse had suddenly become weak, and he had died the same evening. The other case was that of a Spanish steward on a [illegible]. He had been admitted to the hospital with a temperature of [illegible]° F. Several days previously he had been taken ill with fever and chills, and on the day before admission had been found in his berth [illegible]. The blood count gave [illegible] leucocytes, and the Widal and other reactions were negative. There was some albuminuria. Examination of the blood showed severe infection with malaria. Quinine was given hypodermically, but he died on the third day. No autopsy was permitted. As the leucocyte count had been taken immediately after a cold bath, it was probable that this explained the high count. Reference was made by the speaker to the case of a domestic who had been living in Mamaroneck since last June. She had had chills, fever, and sweating at intervals of about one week. The spleen was palpable. Quite a number of crescents were found in the blood. As far as could be ascertained, the woman had not been away from the place where she had been taken sick.

Dr. F. C. Wood presented card specimens of blood sera illustrating the hæmolytic action of serum from one animal upon the blood corpuscles of another species. The specimens also demonstrated that the hæmolysis could be prevented by heating the serum to 56° C. for half an hour, and then the hæmolytic action could be revived in this heated serum by the addition of fresh serum from another animal.

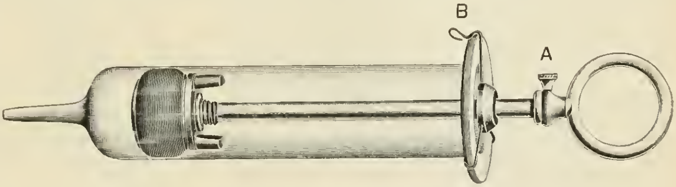
Dissecting Aneurysm of the Arch of the Aorta.—Dr. L. L. Dow presented a specimen of an acute dissecting aneurysm of the thoracic aorta produced by a severe muscular strain. It occurred in a man of forty who had previously felt perfectly well. He denied syphilis and alcoholism, and the previous occurrence of attacks of dyspnœa. He said that while subjecting himself to a severe strain in repairing an engine he suddenly felt that he was losing consciousness, but experienced no pain and afterward remembered no other accompanying sensation. He fell to the floor. The ambulance surgeon found the man unconscious and suffering from extreme dyspnœa. The heart's action was irregular and rapid, and there was a long, loud, medium-pitched blowing systolic murmur heard over the entire præcordium. Its maximum intensity was at the apex, and it was transmitted to the left. The right radial pulse was much smaller than the left. On reaching the hospital the pulse was imperceptible and the skin cold and clammy, the heart's action was extremely irregular, the lungs were filled with the râles of pulmonary œdema. He rallied somewhat under the use of oxygen inhalations and stimulants, and in six hours had sufficiently recovered to give the foregoing history. He rested comfortably through the day, but in the evening complained of inability to use his right arm. Early the next morning, or thirty hours after the onset of the rupture, he was suddenly seized with severe dyspnœa and became unconscious. Examination showed an acutely dilated heart and marked pulmonary œdema. He died in a few minutes. The autopsy was performed eight hours after death. Between the aorta and the pulmonary artery an extravasation of blood could be seen. The heart muscle was flabby, and the cavities moderately dilated and filled with a large amount of post-mortem clot, and a small amount of white blood clot. The mitral orifice admitted the tips of two fingers and its cusps were normal. The aortic orifice was large, but its cusps approximated perfectly. A rent was discovered in the floor of the aorta about four inches from the aortic valve. This rent was transverse, measured three-quarters of an inch in length, and was situated in the floor of a small patch of fatty degeneration of the intima and media, through which it extended. The adventitia was not involved From this rupture the coats of the aorta had been dissected up to within half an inch of the aortic valves. The aneurysm completely encircled the aorta for a distance of one and one-half inches near the heart, and also extended up the inner half of the right common carotid for an undetermined distance, and completely encircled the innominate and left subclavian. At one and one-half inches from the aortic valve was another completely encircling transverse tear of the inner aortic coats. The cavity produced by the dissection contained about three ounces of dark blood clot. In other respects the aorta was normal, except for a few patches of fatty degeneration of the intima. The liver. spleen, and kidneys showed nothing but acute congestion. The adrenals were unusually fatty. The stomach and intestines were filled with gas, and the contents of the ileum and colon were soft and green. The brain and its coverings were apparently normal. There was no atheroma of the cerebral arteries, and no thrombosis or embolism could be made out. and the aneurysm did not enter the skull. There was no evidence of syphilis.

New Instruments.

A NEW ASEPTIC SYRINGE.

By GEORGE L. BRODHEAD. M.D.,
NEW YORK.

SOME months ago, in the attempt to find a syringe which could be made sterile, for use in injecting the bags of Champetier de Ribes, I found that there was practically but one instrument which seemed to meet the requirements, this being the Frank modification of Janet's syringe. There are, however, several serious objections to this instrument, aside from the question of the original cost, which is considerable, and, in fact, almost prohibitive to many would-be purchasers.



The glas barrel upon which the metal extremities are cemented is often broken in the process of boiling, and the cement in some instances softened, thus rendering the instrument useless.

With the kind assistance of the Kny-Scheerer Company, of this city, I have devised a syringe which has many advantages, among which are the following:

First, it can be thoroughly sterilized by boiling; second, the barrel is of glass, and one can readily observe whether the instrument is working properly or not; third, the instrument is simple in construction, and the various parts can be easily replaced; fourth, its field of usefulness is wide, and, fifth, the cost is less than half that of the imported syringe.

The barrel of the syringe is made of heavy glass, is five inches in length, one and one-fourth inches in diameter, with a tip, one and one-fourth inches in length. The upper end of the barrel is flange-shaped, which enables one to seize it firmly with the first two fingers. The plunger consists of a rubber disk (especially prepared to withstand boiling), which is so placed between the broad, flat lower end of the solid steel piston rod and the nut just above it, that, by turning the nut, the disk may be flattened, its diameter thereby increased, and its circumference thus made to fit the barrel perfectly. The piston is held in position in the center of the barrel by a simple device, consisting of three arms of metal which grasp the flanged end of the tube. By releasing one of these arms, the piston can be readily removed from the barrel.

The piston is surmounted by a ring of steel, one and one-fourth inches in diameter, for the introduction of the thumb in operating the syringe. This ring can readily be removed, as it is screwed on the end of the piston and held in place with a small bolt. When it is desired to replace the rubber plunger the bolt is removed, the ring unscrewed, and the nut with the disk taken off. A washer is placed between the rubber disk and the nut, in order that the ring and piston rod may be moved in any direction without in the least altering the shape of the disk. The latter can be flattened by turning the piston to the right, while the nut is fixed within the arms of the device above mentioned, thus enabling one to adjust the plunger without removing it from the glass barrel.

The syringes are of two sizes—the smaller with a capacity of two and one-half ounces, the larger holding about four and a half ounces.

60 WEST FIFTY-EIGHTH STREET.

Medical Items.

Diet in Bright's Disease.—Dr. William Hale White says: "Much has been written about the diet in chronic Bright's disease, and frequently the importance of it has been much exaggerated. The dietary for Bright's disease has even been fastidiously determined by the color of the meat ordered. If any method at all underlies many of the dietetic directions given to patients with Bright's disease, it is that those who order the diets try by means of dieting to diminish the risk of uræmia. But we have no certain knowledge what is the poison which leads to uræmia, and therefore, we can hardly hope to influence it by diet, and indeed, there is no series of cases published showing that any particular diet is more likely than others to lead to uræmia. The great guiding principle in dieting patients suffering from chronic Bright's disease is that, as we do not know what is the cause of uræmia, the best way to avoid it is to give such diet as will keep the patient in the best general health.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending January 11, 1902.

	Cases.	Deaths
Measles	872	28
Diphtheria and croup	310	49
Scarlet fever	277	26
Smallpox	30	3
Chickenpox	96	1
Tuberculosis	239	140
Typhoid fever	27	16
Cerebrospinal meningitis	..	3

Epidemic of Diphtheria at the Boston Navy Yard.—Referring in the report of the Surgeon-General of the Navy to the above epidemic, Passed Assistant-Surgeon Dudley N. Carpenter says the treatment depended almost entirely on antitoxin. Three kinds were tried and all [illegible] apparatus. A glass antitoxin syringe with asbestos packing was used, and the antitoxin injected with antiseptic precautions into the lumbar region. No abscess occurred in any case from the injection. The dose of antitoxin necessary for the individual case varied. The degree of toxemia as shown by the clinical symptoms, the amount of membrane, the time elapsed since the onset, and the age of the patient—all were considered in gauging the number of units to be given.

In cases of moderate severity, among male adults with a natural immunity relatively, only from [illegible] to [illegible] units were given during the course of an individual case. From [illegible] to [illegible] units was the average amount.

A Manila Military Hospital.—In the Journal of the Association of Military Surgeons of the United States, November, Captain John S. Kulp contributes a memoir of one of these institutions.

The bed capacity of the hospital in question was 297, with 57.5 square feet of floor space, and 1,035 cubic feet of air space per bed.

The personnel consisted of 6 officers, 10 non-commissioned officers, 6[illegible] privates, 11 native laborers—a total of 8[illegible].

The work of the hospital was done by soldiers of the hospital corps, no male or female civilians being employed in the buildings.

The administration of the hospital seems to have been very successful throughout, and to have reflected much credit upon its organizers.

Captain Kulp reaches the following conclusions with regard to such establishments:

That the military hospital differs from the civil in almost every particular of patient, administration, and personnel. Its commanding officer possesses greater authority and graver responsibilities than those of a mere medical superintendent. The technical knowledge of decisions, regulations and papers, which is required to protect the interests of the government on the one hand, and to prevent injustice to the soldier patient on the other, can be learned from neither book nor school. In no country can there be obtained a higher class of purely professional talent than in our own, but those trained in the specialty of military medicine must be provided in time of peace. This is the work which the gentlemen composing the association of Military Surgeons are doing, and the reward will come not only in the saving of life and the prevention of suffering, but by assistance of no mean value when the time comes for the final object for which all armies exist—the test of battle.

Restoring Effects of Paraffin.—*The Revue* (Paris, November [illegible]) gives an account transcribed by the *Literary Digest* of a remedy for the correction of disfigurements caused by burns, wounds, or of even those of a congenital nature. The method was introduced by M. de Gersuny. If it is a collapsed nose which it is desired to raise, beneath this organ two or three cubic centimeters of melted paraffin are introduced. The injected mass raises and stretches the skin of the nose, and as paraffin becomes solid at a temperature of 37 degrees C. (98 F.)—that is, at the temperature of the body—it is only necessary to mould it into the desired shape before it cools. The results are said to be very satisfactory. Experiments made upon animals tend to prove that paraffin is not absorbed, but that it remains in place, and that in every direction, around and across it, is developed a web of conjunctive tissue. When the animal experimented upon is killed or dies, there is thus found at the place where the injection was made a sort of conjunctive network, the interstices of which are filled with paraffin. The formation of this characteristic tissue, remarks *The Revue*, permits the hope that the results of the Gersuny method may be durable, and, as a matter of fact, in cases where operations were performed as long ago as two years, there has been no reappearance of the disfigurement.

Casualties During the China Expedition.—Gunshot wounds furnished the largest number of admissions to hospitals for any one cause among the United States soldiers and marines engaged in the Chinese expedition. The total number was ninety-seven, slightly exceeding the combined number of admissions for diarrhea and dysentery, the two most common diseases in the force during hostilities.

During the Spanish-American war there was a total of eighty-four gunshot wounds, with sixteen deaths. Injuries of this class during that period were not only fewer in number, but also decidedly less fatal, the percentage of deaths having been nineteen in the former instance as compared with a mortality of nearly 25 per cent. during the recent hostilities.—*Report of Surgeon-General U. S. Navy.*

Koplik's Sign in Measles.—Koplik's sign in measles does not seem to be always a sure symptom of this disease. This sign consists in red spots on the mucous membrane of the mouth, the center of which is slightly prominent. Widowitz, a physician at Gratz, has found it in 140 cases out of 158—that is to say, in 88.6 per cent. of the cases. He has, however, seen it ten times in German measles, once in a case of follicular tonsillitis, and once in a case of stridulous laryngitis. Rolly has found it in twenty-four cases out of seventy-eight, and has never seen it in other diseases.—Paris letter, *Therapeutic Gazette.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended January 11, 1902:

THE FOOD FACTOR AS A CAUSE OF HEALTH AND DISEASE DURING CHILDHOOD, OR THE ADAPTATION OF FOOD TO THE NECESSITIES OF THE GROWING ORGANISM.*

By JOSEPH E. WINTERS, M.D.,
NEW YORK.
PROFESSOR OF THE DISEASES OF CHILDREN, CORNELL UNIVERSITY MEDICAL COLLEGE

At what age should a child be given food other than milk? Milk contains from seven to fourteen times less iron than the other articles of food. Although the other mineral constituents of the milk are present in the same proportion in which they are contained in the tissues of the child at birth, iron is present in mere traces only. The infant enters the world with a supply of iron in the liver and to a smaller extent elsewhere, which has been stored during intra-uterine life. The child gradually draws upon such store for the manufacture of the blood-coloring matter, which lasts until its digestive organs are prepared to digest food other than milk. The small amount of iron in milk is insufficient for the growth of the child, hence the high percentage of iron in the organism at birth. Late weaning, or the too prolonged use of milk as the exclusive food of a child artificially fed, causes anæmia. This is the first pathological condition which we mark as arising from failure to modify the diet of a child at the proper time. The chemistry of milk, the physiological chemistry of the child, and the physiology of the digestive organs denote that such change should be made at a fairly definite time.

From the seventh to the tenth month, according to the degree of development of the child and the advancement of dentition, the ferments which digest farinaceous substances are present in sufficient quantity to indicate that a change of food should be made. The rapid development and the functional activity at this time of the glands which secrete the diastasic ferments make it wholly manifest that nature intended that milk should be supplemented first by farinaceous food. The chemical composition of the various farinaceous foods determines at once which one of these has the highest physiological value. Oatmeal is rich in all the constituents which are essential for the growth and development of the child at this age, and is peculiarly rich in proteid, fat, and mineral matters. Oatmeal is amongst the richest in iron of the vegetable foods, and contains more iron per 100 dried parts than beef. Proteid is present to the extent of about 14½ per cent.; fat 10 per cent.; mineral matters 2 per cent.; starch 30 per cent. Of the total nitrogenous matter, 94 per cent. is in the form of proteid, and therefore available for tissue-building. Owing to the large amount of cellulose or woody fiber in oatmeal it is indigestible unless this is removed by straining. By careful cooking and straining it is one of the most digestible foods there is. A tablespoonful of oatmeal jelly may be added to every second bottle at first, then every bottle, and later the amount may be gradually increased to two ounces in every bottle. In the summer months it is sometimes necessary to use barley gruel (from the whole or pearl barley) instead of oatmeal. Barley is poor in fat, proteid, and iron, as compared with oats. It is seldom wise to *begin* the use of farinaceous food with a child during the warm months, as it is prone to cause fermentation and diarrhœa.

Milk, supplemented by cereal gruels, should, with exceptional instances, constitute the child's food until the end of the first year. Soft boiled or poached egg mixed with bread crumbs from stale bread may be added to the diet at the beginning of the second year. Egg contains much proteid, fat, and mineral matter, especially salts of lime, phosphoric acid, and iron. The nuclein of the yolk of egg contains phosphorus and iron in organic combination. As mineral matters are most easily absorbed where they form part of an organic compound, the iron and phosphorus in the yolk of egg easily enter the blood. The fats in the yolk of egg are the same as in butter, and have the same nutritive value as these. Their presence in the form of an emulsion in the yolk makes them very easily digested. The great richness of yolk of egg in fat, in lime salts, and in organic compounds of phosphorus and iron makes it a peculiarly valuable food for a young child. The nutritive value of egg is due almost entirely to proteid and fat. Of these there are of proteid 14.8 per cent., and fat 10.5 per cent. To begin with, only a small portion of one egg should be given twice a week, gradually increasing the amount until the entire egg, soft boiled, is taken at a feeding. Later this may be given two or even three times a week.

During this period the child may be allowed a dry crust of stale bread twice a day. A hard crust is highly digestible, and is a good thing for a child as soon as it has the teeth with which to chew it. The labor of the jaws which is involved in eating a piece of hard crust develops the masticatory organs, and especially the jaw bone. If the jaw is imperfectly developed, the teeth are crowded and imperfectly developed, and dental caries is inevitable. Decayed first teeth cause septic conditions of the mouth, and frequently lead to enlargement of the cervical lymphatics, which may become tubercular, and the whole system may thus become infected. Much digestive disturbance is unquestionably due to the same cause.

Disuse of the jaws starves the areas supplied by the maxillary arteries, as these vessels are not fully developed. The mechanical stimulation of chewing leads to the outpouring of a salivary secretion richer in amylolytic power than the secretion coming without stimulation. These several matters should not be overlooked, it seems to me, in the feeding of children, particularly in these days, when it is customary for the medical profession to direct that all food should be scraped, minced, chopped, strained, etc.

The child may also be given stale bread broken in milk, by way of furnishing variety to its food. Bread is one of the most nutritious of foods. Three-fifths of it consists of solid nutriment, and but two-fifths of is water. There are but few foods of which the same can be said, and it is not true of any animal food.

---

*Read at meeting of New York Academy of Medicine, January 16, 1902.

At the end of fifteen months, a child (when normally developed) is getting whole milk, oatmeal or barley, a soft-boiled or poached egg twice or three times a week, a dry crust of stale bread twice a day, and perhaps a little bread and milk.

For the best results and the least disturbance of digestion, cereals should be given without sugar. Sugar has a strong affinity for water, and a large amount of water is required to hold it in solution. Water for this purpose is extracted from the capillaries of the mucous membrane of the stomach, thus interfering with the blood supply for the gastric secretions, causing a retardation of the digestive functions. This is the reason why digestion is delayed and deranged by sugar and all sweet desserts. The large amount of water that is required to hold sugar in solution is the explanation of its causing constipation, and of its interfering with all the secretions; just as in diabetes there are unrelievable constipation, dry eczematous skin and more or less diminution of the secretory functions, so in children in whom sugar is a large factor in their diet are all these perversions of the vital functions met.

Fruit may be given now, and sometimes much earlier. Orange juice and prune pulp are the first fruits for a child. When there is constipation these are allowable very early in infancy. Every means, however, should first be tried to overcome this by adjustment of the diet, before resorting to fruit juices. Fruit juice should be independent of and about an hour before a meal.

You must have become impressed with the fact that I have been directing foods rich in proteids, fat, carbohydrates, and mineral matters. It is on physiological grounds solely that such foods are recommended. Feeding of children comprises the nursing period (breast or bottle), a transition stage, just spoken of, and a third or final period, which we are about to consider. It is this final stage which is found most perplexing. Just here the physician finds himself utterly rudderless in the feeding of a child. What has been written about it is diametrically opposed to the teachings of chemical physiology. Experience proves it to be erroneous.

Choice of food adapted to the wants of the growing organism necessitates a clear understanding of metabolism.

Many look upon metabolism in a child and an adult as identical, whereas they are quite diverse. Metabolism in an adult is using up and renewing the materials of which the body is composed, and covers but a minor and comparatively unimportant part of that process in a child. In a child materials are being stored for fresh growth. Storing for future needs is the paramount desideratum in the diet of a child.

For this reason, certain constituents are required in relatively much larger proportions in a child than in an adult.

The bony framework requires little or no repair in an adult, hence earthy salts are unimportant in an adult as compared with their grave necessity in a growing child.

Fat is essential for cell growth in a child, and as we shall see later on, may be properly classed as a tissue-former during the period of rapid growth of the nervous system and of the skeleton.

Carbohydrates may be largely dispensed with or substituted for in an adult. In a child they are necessary in order to meet the large demand for heat and energy, and thus to protect and shield from oxidation the proteids and fats that these may be stored for future needs. Muscular deposit and growth are not possible without an abundance of the shielding carbohydrates in the diet of a child.

At this age, too, food must be selected with reference to its influence on the development and functions of the digestive organs.

The excessive use of highly digestible food which prevails so extensively often leads to actual debility of the intestinal muscular walls. The muscular wall of the intestines becomes atrophied like every other muscle if it has not work to do. We must see, therefore, that the diet of a child does not lack bulk for the mechanical stimulation its presence gives to the intestinal movements. The intestinal secretions exert no chemical action on the proteid constituents of the food, but play a great part in the digestion of the carbohydrates. During the period when the intestinal functions are developing and increasing in functional activity, these functions should be stimulated that they may attain their full development. For the complete development of this function and of the muscular walls of the intestine, carbohydrates and vegetable food should enter largely into the diet during growth and development.

In an adult, food serves two great purposes in the body, the supply of materials for the repair of the tissues, and, secondly, as a source of energy which can be converted into heat and nervous and muscular work. In a child there is necessity for materials for another supreme purpose, viz., the structure and development of new parts.

If we are to proceed in complete accord and follow out readily and clearly what we have before us for consideration, we must start with the proper groundwork. I beg to remind you, therefore, that the essential elements of food are of five chief classes, viz.:

(1) The nitrogenous, the chief of which are the proteids found in animal food, cereals, and certain vegetables. (2) The fats. (3) The carbohydrates. (4) Mineral elements, of which the salts of lime, potash, soda, and iron are the chief. (5) Water. The repairing of the structures in an adult can be performed by the proteids and the mineral constituents, and by these alone; all the classes can and do supply energy and heat.

For the perfect development of the growing structures in a child, proteids, mineral elements, fat, and carbohydrates are required in relatively larger proportions than in an adult. These will be considered seriatim.

Nitrogenous Matter.—No formation of tissue can occur without proteid. An animal fed only on non-nitrogenous food, such as fats and carbohydrates, will inevitably starve to death in time. Protoplasm, the vital constituent of every individual cell, contains nitrogen; fats and carbohydrates contain no nitrogen, therefore none of the tissues of the body can be made from these non-nitrogenous foods. Nitrogenous matter is essential to every vital process, no cell growth can occur without it.

The voluntary muscles in man constitute about 42 per cent. of the total body-weight, in the new-born child, 23.5 per cent. Proteids are the material from which muscles are built up, and proteid in large amount must be supplied to a child for the development and growth of muscular tissue alone. It is equally necessary for the proper development of the other structures of the growing organism. The importance of a sufficiency of proteid can hardly be exaggerated. Much of the feebleness, flabbiness, and pallor, and the stunted, ill-developed bodies one so often sees in children, are no doubt due to a lack of it.

We have thus conclusively demonstrated the essential necessity of an abundance of proteid in the diet of a child.

Mineral Ingredients.—Food must contain certain mineral or inorganic as well as organic principles. Mineral constituents are necessary for the building up of the child's body, and a lack of them will produce the same evidences of malnutrition and of imperfect development as deficiency of proteids. *The mineral portions of bone are permanent*, and require little or no repair in an adult, hence the great importance of a relatively larger supply of these elements in the body of a child.

Nitrogenous materials or albumins form the groundwork of every living cell. The phenomena of life are dependent upon and center in their presence. The nuclei of these cells are rich in phosphorus, iron, and variable amounts of mineral salts. No formation of cells for fresh growth can occur without phosphates and other mineral salts; they are necessary to every tissue: salts of lime and magnesia for the bones; phosphate of potash for the muscles; phosphates and potash salts for the corpuscles of the blood; and chlorides and soda salts for the plasma.

As physiological physicians, however, we must not regard these constituents as simple mineral elements. The mineral matters of the food, to be properly assimilated, must be in their natural condition, which is that of organic combination with the proteid substances. Animals in which milk alone is a sufficient food die of inanition if the mineral substances are extracted, and the result is the same if these elements are added to the caseine, fat, and milk-sugar, the organic combination being broken up. In the breaking up of the organic combination or destruction of the chemical union between proteids and mineral substances is to be found the sole etiological factor of scurvy in the artificial preservation of foods by heat.

In raw milk, egg, cereals, and certain fresh vegetables, mineral salts are all found in organic combination, ready to enter the blood and to be assimilated by the various constituent parts of the organism.

The inorganic tissue-builders, like the proteids, are concerned in building up the child's body, and any deficiency of them will produce much the same symptoms as deficiency of proteids. The symptoms produced by a lack of these are often mistaken for a deficiency of proteids, and meat juice, scraped beef, etc., given, with the result that disease of the nervous mechanism, and of the blood, is super-added to the existing morbid phenomena.

Fat.—Fat commands an immeasurably more exalted place in the diet of a child than in an adult. Fat serves as fuel to maintain the temperature of the body at the necessary standard, the heat being converted into force and energy for every action and function of the organism.

77.5 per cent. of the heat lost to the body is by conduction and radiation and evaporation from the cutaneous surface. The surface of a child is relatively three times as great as that of an adult. The larger the cutaneous surface relative to the size of the body, the greater is the amount of heat lost by conduction, radiation, and evaporation. This relatively large and rapid heat loss in the child makes an ample supply of the chief body fuel, fat, an absolutely indispensable condition.

Bone marrow, brain, and nerves are the tissues which are richest of all in fat.

Brain tissue contains	8 per cent. fat.
Nerves contain	22 per cent. fat.
Marrow of bone contains	96 per cent. fat.

These tissues are all increasing in weight and functional activity with marvelous rapidity, the brain doubling its weight during the first two years of life. In these structures the child is laying down a large amount of tissue rich in fat, and a child whose diet is deficient in fat rapidly loses vigor, and is extremely prone to suffer from anæmia, laryngismus stridulus, convulsions, and later, bronchitis, and a tendency to catarrhal affections of all mucous surfaces. In this connection it should be remembered that the chief seat of the formation of the red blood corpuscles is the red marrow of the bones, especially of the bones of the skull and trunk, and of the ends of the long bones of the extremities.

If a child's food is deficient in fat, the bony structures develop slowly and imperfectly, dentition is delayed, and a later manifestation is rickets with anæmia. In the diet of a child, fat plays some part in the formation of young tissue which cannot be performed by any other food constituent. Abundance of fat should be the main characteristic of the diet of infancy and early childhood. A child of five requires half as much fat as a man doing moderate work.

To provide materials for repair, for the secretions, for the generation of heat and energy, and in addition for making the new tissues of the growing structures, a child requires proteids, mineral matters, fat, and carbohydrates, in larger proportions than an adult. The mineral ingredients must be in organic combination with the proteids. Milk, farinaceous substances, especially oatmeal, bread, and egg, not only contain these food elements in eminent proportions, but they exist in organic combination. These are pre-eminently the physiological foods of early childhood.

The peculiar value of carbohydrates to a child will receive due consideration when treating of flesh foods.

Flesh Food.—At what age should a child be given animal food other than milk and egg? The time when meat should be given to a child turns on its influence upon metabolism. Meat and meat preparations are characterized by the large amount of nitrogenous matter which they contain. Nitrogenous matter markedly increases the metabolism of the body; and it increases the metabolism not only of the nitrogenous, but also of the non-nitrogenous constituents as well.

Beef contains from 20 to 21 per cent. of nitrogenous matter, therefore four times the amount that is present in milk, and about double the amount contained in the principal farinaceous substances. Of the total nitrogenous matter in meat, 15 per cent. is present in the form of extractives. Meat extractives have no nutritive value. They are not tissue-builders; they are not oxidized in the body, and therefore are useless as sources of heat and energy. These extractives excite the nervous system, and may act injuriously on the young child by over-stimulating the nervous system, by taxing the organs of excretion, and by stimulating unduly metabolism.

Of the total nitrogenous matter in beef, only 5 to 6 per cent. is in the form of proteid, and therefore available for the two main purposes of food—tissue building and the production of heat and energy and work.

The proteids may be divided into those of animal and those of vegetable origin. There does not appear to be any essential difference between these two classes. Vegetable proteid is equal in nutritive value to animal proteid. Somewhat less of the proteid of vegetable food is digested and absorbed than that of animal origin. This is largely due to the envelope of indigestible cellulose, to woody fiber, and other indigestible materials, rather than to any peculiarity of the proteids themselves. This may be overcome by soaking in water overnight, careful cooking, and straining. With such care in preparation, the proteids of cereals are absorbed as perfectly as those of animal origin.

The body possesses the power of converting any vegetable or animal proteid into the proteids which are contained in its serum and liquids. Vegetable proteid is not as valuable as animal proteid for the construction and repair of the body, and for the supply of nitrogenous material as the active principle of its secretions, and is free from the crystalline extractive bodies, which exist in meat in the proportion of 1 to 2 per cent.

The excess of proteid and extractives contained in flesh foods acts as a stimulus to some reflex nervous mechanism through which metabolism of all tissues is hurried on. In a child combustion is relatively greater than in an adult for two reasons—first, the smaller organism having the relatively larger surface carries on a more rapid metabolism per unit of body weight; second, the metabolism of the growing parts in the body is from 2½ to 6½ greater than that of the parts already formed.

The proteids and extractives from flesh foods stimulate the naturally active metabolism of a child and prevent storage of the tissue builders. Over-stimulation of metabolism by an excess of animal food interferes with laying on flesh—fat or muscular flesh. Carbohydrates are easily oxidized, and their oxidation serves to protect the proteids and fats from consumption. The shielding from oxidation of these requisites for the growth and development of new structures is a matter of profound value and consequence to a growing child. Carbohydrates and fats by their sparing action increase the store of proteids. A child increasing its capital of flesh tissue should have proteid-sparing food in abundance, and food which stimulates metabolism should only be given in such quantity as is necessary for the actual requirements of the system's daily needs.

The brain appears to require nitrogen, which can only be obtained in a concentrated form from animal sources. Highly nitrogenized food is a nervous food valuable where bodily energy and intellectual capacity must be assured without taxing the digestive organs.

Muscles do their work upon carbohydrates, a child with its unceasing, acrobatic, muscular feats, should have an abundance of that food which is regarded as the most valuable source of muscle-energy, and the sensitive nervous system should not be stimulated by a nervous food.

One of the most unfortunate, wholly unconsidered consequences of an early and liberal meat diet is the disrelish it creates for the physiological foods of childhood—cereals, vegetables, milk.

A child that is allowed a generous meat diet is certain to refuse cereals and vegetables. Meat, by its stimulating effect, produces a habit as surely as does alcohol, tea or coffee, and a distaste for less satisfying foods.

The foods which the meat-eating child eschews contain in large proportions certain mineral constituents which are essential to bodily nutrition and health, and without which the processes of fresh growth and development are stunted. This brings us to the kernel of our subject.

The chemical processes in the organism are dependent upon alkaline-reacting tissue-fluids.

In the combustion of flesh foods (proteids) in the organism sulphuric acid is formed, and death may be caused by a lack of alkaline bases necessary to neutralize this acid product.

The function of every individual cell, the nutrition of every tissue, the perfect consummation of every chemical process in the organism is dependent upon alkaline-reacting tissue-fluids, which alkaline reaction is due to alkali-carbonates.

These alkaline bases are also of great importance as constituents of certain secretions, such as the saliva, the pancreatic and intestinal secretions, and for the transportation of carbonic acid in the blood that it may be removed from the system.

For the processes of fresh growth, for the construction of bone, muscle, etc., mineral constituents are likewise required in large proportions.

For the supply of alkali-carbonates for the tissue-fluids, for the alkalinity of the blood and the numerous secretions which are poured forth in almost incalculable quantities during every twenty-four hours, for the transportation and elimination of carbonic acid from the system, to neutralize the sulphuric acid formed in the combustion of the proteids, for the passage of the proteids from a soluble to a coagulable state, and for the organization of the proteids, for the supply of the large amount of minerals needed for the growth of the bony framework, and for the tissues of the growing child, alkaline bases must be introduced into the system in large amount. The nutritive value of food substances is generally estimated by their proportions of proteids, fats and carbohydrates. In a child the mineral constituents are equally important with any of these.

These mineral constituents cannot be introduced into the system in an assimilable form except in organic combination with an albuminous molecule, and are only found in organic combination in sufficient proportions to meet the large demands in a child in certain vegetables and cereals which obtain them direct from the soil as provided by nature.

A lack of these mineral constituents will not only cause all vigor and vitality to dwindle and die out, but indeterminate disease processes supervene in consequence thereof.

I have met with cases in which every tissue of the body was in a state of suffering; the capillary circulation of every organ deranged; every secretion disturbed and altered, a general disease of every part, all arising from a deficiency of the normal food constituents, chiefly the mineral elements.

In numerous cases in which all the means that our art could devise had been employed, not only with lamentable failures, but with deplorable effects, I have had the happiness of seeing this universal morbid state remedied promptly and permanently by adjustment of the diet to the necessities of the growing organism, supplying the starving tissue-cells with proper food constituents in an assimilable form.

We should, moreover, acknowledge the value of vegetable food in the construction of the coloring matter of the blood. There exists an interesting relationship between the blood-coloring matter and the vegetable-coloring matter, and vegetable food is probably the chief factor in the production of blood-coloring matter. Long ago Bunge affirmed that plants constitute the normal supply of iron to the body. Oatmeal is among the richest in iron of the vegetable foods, and, according to Boussingault, contains more iron per 100 dried parts than beef. Spinach and apples likewise contain a great deal of iron.

The urine in children is considerably richer in uric acid and ammonia than the urine of adults. The elimination of uric acid and ammonia diminishes promptly with the use of vegetable food.

Salts of the vegetable acids which are so abundant in vegetable food become oxidized in the body to carbonates, and the bases thus derived tend to alkalize the urine. From this follows the familiar fact that urine of herbivorous animals is alkaline, and that the human urine may become alkaline when a vegetarian diet is maintained.

The present drift of teaching is to direct beef or beef-juice as food in fulsome quantities to very young children. An infant of ten months is ordered half an ounce of beef-juice daily, and this is increased to three ounces a day by the twelfth month. Scraped raw beef is given with equal lavishness to a child of eighteen months. Medical writings have propagated and popularized this unfortunate error.

The evil fruit, the pathological consequence of this unphysiological and abnormal feeding, is to over-stimulate the delicate nervous organization, with undeveloped controlling centers and almost completely developed sympathetic nerves; to tax the system with incompletely burned, merely charred, excretory products; to render the urine, which in the young child is normally highly acid, abnormally so; and in its train, incontinence of urine, rheumatism, chorea, rheumatic tonsillitis and torticollis, night terrors, urticaria, angio-neurotic œdema, and finally, from poisonous excrementitious products, anæmia, acute convulsions, and petit mal.

There are more so-called nervousness, anæmia, rheumatism, valvular disease of the heart, and chorea at the present time in children from an excess of meat and its preparations in the diet than from all other causes combined.

Physiology and physiological chemistry make it unquestionably clear that meat should not be given in early childhood. Experience demonstrates and proves the accuracy and the value of physiological teaching.

The ever-active, muscle-laboring, growing child, with its rapid heat loss, should have an abundance of cereals, vegetables, and milk in its diet, to meet physiological requirements.

Children in whom meat is a large factor in their diet have not the robustness and vigor, the freedom from attacks of ill-health, witnessed in those who have meat but sparingly. A disproportion of animal food in the diet of a child, by overstimulation of metabolism, leads to imperfect tissue-nutrition, delicacy of constitution, and irritability and peevishness of disposition; the resisting powers of the organism are impaired; the susceptibility to disease heightened. Meat juice should not be given to a healthy child before two years old, and then in quantities not to exceed half an ounce to one ounce three times a week. The healthiest children are those who have meat every second day only, up to the age of five and six years.

Suitable adaptation of the different food constituents to cover the large demand for heat and energy, and for the storing of proteids, minerals, and fat for *future needs*, is the paramount consideration in the diet of a child.

An abundance of carbohydrates is essential to the growing child, as the stored energy which is thus supplied protects the circulating albumins from undue destruction. There must be sufficient fat and carbohyhrates in the food to cover the large demand for heat energy, and nervous and muscular work, that the proteids may be protected and stored. Muscular flesh deposited during growth is permanent, and lasts as long as life itself; whereas muscular flesh built up by forced exercise in an adult is lost as soon as the exercise is discontinued.

Foods rich in carbohydrates and fat, along with a moderate proportion of meat, will be the ones on which the most abundant and most lasting deposition of flesh—fat and muscular flesh—is to be assured for future and far-distant needs. Such foods are to be found in oatmeal, cornmeal, cream of wheat, hominy, rice, potato, bread, and other farinaceous substances, egg, vegetables, and milk, with a minimum of flesh food. These foodstuffs are at the same time rich in potassium and other salts, which latter resemble those of the blood, muscles, and bone, and which are essential to health; and to the normal reaction of the secretions, while flesh food contains only mere traces of potassium.

Conclusions.—Nature, or, to be specific, chemistry, physiology, and chemical physiology, have furnished unerring guides for the feeding of children.

The time when and what farinaceous substances should be given is wholly evident.

Meat juice is contraindicated in very young children, owing to its exciting effect on the nervous centers, and the loading of the system with extractives which tax the excretory organs.

During all the years of early childhood, meat and its preparations should be given only sparingly on account of their overstimulating metabolism, but chiefly for the reason that they create a distaste for cereals, fats, and fresh vegetables, thus depriving the system of materials needed to shield the proteids from oxidation that they may be stored for future needs, and of the necessary mineral salts which vegetables obtain direct from the soil.

In a child, with its relatively large cutaneous surface and correspondingly rapid heat loss, the large demand for calories must not be covered by proteid to any considerable extent, otherwise there is a lack of deposition of proteid—or of muscle growth. Increasing quantities of carbohydrates and fats in the food decrease proteid metabolism; a more lasting deposition of proteids for future needs is thus brought about.

To provide the mineral constituents necessary to maintain the normal reaction of the fluids of the body when these elements are being appropriated in large proportions for the growth of bone, muscle, etc., vegetables which obtain these elements direct from the soil must be consumed in fairly liberal proportions.

25 West Thirty-seventh Street.

THE NATURE OF CUTANEOUS EPITHELIOMA, WITH REMARKS ON TREATMENT BY THE X-RAYS.

By CHARLES WARRENNE ALLEN, M.D.,

PROFESSOR OF DERMATOLOGY IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL, CONSULTING DERMATOLOGIST TO THE RANDALL'S ISLAND HOSPITALS, CONSULTING GENITO-URINARY SURGEON TO THE CITY HOSPITAL, ETC.

THE cause of cancer is a subject of such great importance that for many years scientists, laboratory investigators, and clinicians have put forth unusual effort in its attempted solution.

The nature of cancer is to-day being investigated by thousands of workers, and still little more is accomplished than for one investigator to show that another is wrong in his surmise that he is approaching the goal.

It is, however, highly proper for us to discuss these unsettled questions, for it is not an unknown thing in the history of medicine that problems in whose solutions the laboratory has failed have been fairly well settled by physicians among themselves from clinical and other considerations.

Ruskin said: "Hundreds of people can talk for one who can think; but thousands can think for one who can see." We might go a step further than this in thinking of those who discover the germs of cancer from year to year, and add that there are thousands who think they see the germ for one who proves definitely that he has made a correct observation.

While we cannot quite agree with Roswell Park's jocose remark that we are "living in the tropic of cancer," we may still claim this as an epoch in which the topic of cancer is receiving almost a full share of attention.

Among recent discoverers of microbes is Doyen of Paris, who, according to dispatches published on Christmas Day, has found one which he calls the *Micrococcus neoformans*. Dr. Doyen long ago noticed in cancerous juices certain diplococci and small chains with difficulty distinguished from cellular granulatumor. When examined at the end of two or three months he found them as active as when in the tumor.

Experimenting with the new microbe he was able to reproduce cancer. Later, by subcutaneous injections of a sterilized solution of toxins derived from the new microbe, he succeeded in producing in cancerous patients a reaction resembling the effects produced in tuberculous subjects by tuberculin, and tending to prevent a return of the cancerous growth. He does not assert that his experiments are conclusive, but says that the result of trials carried on for six months has been most satisfactory.

Another recent discovery is that of Max Schüller of Berlin, who found colonies of a new parasite, having the appearance of small grayish white points in cancerous tissue. Here, too, inoculation experiments were thought to be successful. These observations have been controverted by Hauser of Erlangen, who believes that what Schüller saw were not microbes at all but so-called "stone-cells," such as are found in cork, and that the inoculation experiments had produced masses of granulation tissue only, and not cancer.

Fortunately from the patient's side, and unfortunately from the side of science, physicians treat successfully many affections long before their exact nature has been determined. On the other hand, the discovery of the precise etiology does not always lead to any improvement in therapy. It is chiefly in the direction of prophylaxis that our hope lies as a result of the nature of cancer being determined.

Skin cancer, from its location and relative frequency, offers a favorable field for study in both etiological and therapeutical directions. There are three clinical forms of skin cancer, which is now for convenience designated "epithelioma," although we all recognize the fact that all carcinoma is of epithelial structure.

We have first the rodent ulcer type, which is the common, or perhaps the commonest, form familiar to us clinically as the rather rounded ulcer upon the eyelid, side of the nose or cheek, as almost always occurring in the upper portion of the face, rarely on other portions of the body, and going on to deep and widespread destruction of tissue.

Second, epithelioma proper, or carcinoma of the rete Malpighii, typified in cancer of the lip.

Third, epithelioma springing from sebaceous-gland structure. This form must be considered rare, while that arising from sweat-gland structure is still more so.

Morphologically we have the three clinical varieties:

1. Flat or superficial (nodular stage of rodent-ulcer type—epidermoid).

2. Infiltrated or nodular (imbedded or elevated).

3. Papillomatous or berry-like growths (the vegetating or fungoid cancer being an exuberant form of the deep-seated variety).

In the rodent-ulcer type, which may at times also begin as a soft-brown tubercle, the changes keep pace with one another, so to speak, the ulceration of the center being proportionate to the infiltration of new territory. The term rodent ulcer should be dropped, as tending to confusion by the impression conveyed that it differs from epithelioma. Furthermore, the ophthalmologists have used the term for an entirely distinct affection (*ulcus rodens corneæ*). We are justified, however, in speaking of a rodent-ulcer *type* of epithelioma. We have here a very slow growth, with an ulcer of rounded form tending to crust over, and presenting a raised, rimmed border of pearly tissue, which breaks down readily under mechanical pressure or the curette.

The starting point is usually a warty growth, *verruca seborrhoica*, often wrongly called senile warts because more common in the aged, an irritated mole, pressure of glasses, small skin lesions of benign nature which have been persistently picked, etc. Under the microscope a particular type of structure is disclosed. This does not, of course, mean that the origin has been in gland tissue. It is essentially a proliferation from the lowest layer of Malpighian cells. That which gives it its chief character is the downward growth in parallel layers of cells. The dense connective tissue encountered in the form of bands about the cells tends to prevent the latter from branching out widely, or being thrown off to form metastases in neighboring lymph-nodes or eventually in distant organs. Histologically this type, which may assume several clinical forms and show great irregularity of development, never produces cell-nests, and this particularly distinguishes it from the second type, of which cancer of the lip is, as I have said, a good example.

The second variety, which is rarely found associated with the first as a mixed type, shows a tendency to form horny epithelium and nests, in both of which respects it differs from the rodent-ulcer type.

There is here, too, a greater tendency to invade nearby nodes, though, excepting in lip cancer, this is not marked. The third type, which springs from sebaceous-gland structure, may produce tumors of fair size, but does not seem to possess great tendency to metastatic action. Here, too, at the edge of the necrotic or ulcerating central portion is a pearly margin.

The rodent-ulcer type is seen in advanced middle age, while other forms of cutaneous cancer attack those somewhat older, fifty-five years being, according to Roger Williams, the average. As I have pointed out elsewhere, it may occur in quite early life. The nodular form, it must be remembered, can exist for a long time as a firm bean- or pea-sized elevated lesion of skin color, yellowish, grayish brown, or pinkish, with perhaps some telangiectatic vessels coursing over its summit. The date of onset is not to be set down at the time this becomes scratched, denuded of its thin epiderm, or changes rapidly into an ulcer.

There is another clinical form known as the atrophic, in which the change into an ulcerating process is slight, or does not occur at all, or quickly cicatrizes, and the lesion may even shrink into insignificant proportions, at least for a time. Contrasted with this is the form called by the French *térébrant*, with rapid destructive effect upon all adjacent structures, through cartilage and bone, destroying the eye and penetrating the skull to lay bare the brain.

The chief theories of causation are briefly:

1. Infectivity of epithelial cells (toxic cause of overgrowth).

2. Proliferative overgrowth of misplaced cells (Cohnheim's theory, predisposing).

3. Effects of microorganisms (parasitic or specific-germ theory).

Considering the first theory, we have in the infective granulomata some toxic agent actively employed to determine the overgrowth. Here, however, if the toxic agent be destroyed, the cell proliferation ceases, while in epithelioma which goes on for years with continued cell multiplication we can hardly conceive of a similar toxic agent persisting.

We may, however, fall back upon what Adami has called the "habit of growth," which persists in cell-formation and purposeless proliferation long after the originating influence has been withdrawn.

The theory of infectivity is but little strengthened by the fact that a previously healthy skin-surface, brought constantly in apposition to an ulcerating cancer, may—though rarely to be sure—become affected, just as is occasionally seen in those later lesions of lues which are supposed no longer to contain specific germs or to be heteroinoculable. The cancer patient is, however, by the fact itself a susceptible subject, while the individual with lues is presumably immune to further infection of the same nature.

Accidental inoculations upon the subject himself, as of the upper lip following cancer of the lower, or upon another—man and wife—as in Cases II and XII of the series of fifty cases on which this paper is based, and a few experiments in transmission to animals, are to be explained by the parasitic theory quite as well as by that of infectivity.

There appears to be great difficulty in voluntary transmission to animals—success following attempts with sarcomatous oftener than with epitheliomatous tissue; and reports of the latter have usually not been credited.

In a review of recent work bearing upon the infectious theory of malignant neoplasms, George Blumer* maintains that successful inoculation cannot be considered proof of an infectious theory, and in this he is upheld by Hanau and Loeb. He claims that an attempt to find a parasitic origin has failed entirely, and that work done under proper precautions has almost always led to the conclusion that new growths are sterile.

The second, which is practically Cohnheim's embryonal theory, need not detain us. It undoubtedly suffices to explain some forms of new growth, but not such as we are now considering.

The embryonic origin of certain epitheliomata springing from moles is strengthened by Unna's observation that nævi are made up of cells which have separated during fœtal life, or shortly after birth, forming "rests" which later in life, through trauma or infection, result in tumor formation. The theory applies, therefore, to predisposition rather than to the actual disease.

That epithelioma frequently develops after an injury to the part does not help us much, because we know how injury of a part produces the requisite conditions making possible the actual onset of affections of undoubted germ origin.

The theory of local irritation might therefore be defended, since all are familiar with the extreme frequency with which skin cancer develops upon surfaces previously inflamed, irritated, and altered by disease, scar-formation, etc.

Old patches of lupus, horny seborrhœa, cutaneous horns, senile, arsenical, and other warts, moles, nævi, and cicatrices from burns, are common forms of pathological change in skin tissue favoring epithelioma. Prolonged irritation elsewhere, as in stricture, fissures, fistulous passages, leucoplakia, adherent prepuce, pressure of pessaries, etc., leads often to the same unfortunate ending. Irritation is also operative in the chimney-sweeper's cancer of the scrotum, formerly so common in England. In case XXXVI of epithelioma of the tip of the nose and upper lip, referred to me by the kindness of Dr. Lyle, there was a history of occupation in which the nostrils were constantly filled with black soot.

Other instances are afforded in those cancers beginning in bronchial nodes among those who work in cobalt and arsenic ore and who inhale the dust. It would seem that, as Adami claims, when cells are over-stimulated beyond their functional activity, they tend to use up their excessive force in overgrowth.

Coming now to the parasitic theory, we find much to make the latter seem probable, aside from what has been accomplished in laboratory investigations.

New territory is invaded and involved much in the same manner as in diseases of known parasitic origin, lupus, tuberculosis, ringworm, erysipelas.

The new growth of epithelium takes place in such a manner as to suggest an irritant such as rapidly multiplying parasites in the tissues might produce. The vast majority of epitheliomata occur on exposed parts open to infection and follow injury, often of a nature to open the surface and invite infection. In a clinical study of erysipelas which I published in December, 1898, I found that 50 per cent. of the 100 cases originated in some preceding skin lesion or solution of continuity of tissue. I cite this simply as an instance of a recognized infectious process bearing by analogy upon the question in hand. In the fifty cases of epithelioma, upon which this paper is based, about the same percentage holds good. Epithelioma, I might say in passing, has been seen to disappear after an intercurrent attack of erysipelas, just as has been observed a number of times in lupus and lupus erythematosus, and might be explained by an antagonism of germs fighting for supremacy. In localized cutaneous tuberculosis we have a somewhat similar condition, and one in which secondary effects of a general nature may occur if the local affection be not radically destroyed at a sufficiently early period. Before passing from analogy which should be of some assistance, I would call your attention to molluscum contagiosum, which is so similar in growth and cellular proliferation to epithelioma and worthy of its other name. benign epithelioma; this is an auto- and heteroinoculable affection, now generally believed to depend upon parasitism. Just as in the case of epithelioma. observers are not in accord as to the identity of the parasite, still practically all agree such must be the cause. We shall not here enter upon the merits of the question as to whether epithelioma is caused by blastomycetes, protozoa, coccidiæ, bacilli, yeasts, rhizopods, or other animal or vegetable microorganism. Most observers of late have concentrated their attention upon large bodies similar to round cells, surrounded by protoplasm and encapsulated. They are formed chiefly at the extending margin of the patch, or at the waxy rolled ring which constitutes the chief clinical feature of the affection. This margin is so uniformly present and characteristic with its cartilage-like rolled border, no matter what the appearances of the entire area involved may be, that, to my mind, it points strongly to a common cause of definite nature, and not to a haphazard effect. Epithelioma differs materially from other cancer in a clinical sense only up to a certain point. There is less malignancy in all the early stages and little tendency to involve lymph nodes; but once the confines of the skin have been passed, it rapidly and malignantly invades contiguous structures, not stopping at bony barriers.

It is interesting to note that Borrel of *Annales de l'Institut Pasteur*, Vol. XV, 1901, comes practically to the conclusion that recent laboratory work has been of a non-convincing or negative character. The parasitic theory is attractive, he says, but at present there is no evidence before us to support it. As we approach the question of *x*-ray treatment, it is interesting to note that Williams of Boston in his excellent work on "The Röntgen Ray in Medicine and Surgery," just published, makes a rather strong point in support of the parasitic theory, which theory, as my preceding remarks indicate, I favor. He says, "A therapeutic measure cannot, of course, point out the cause of a disease, but it may throw suggestive light upon it. For example, in the radiation from a vacuum tube good results are produced in a disease where the cause is known to be due to a microscopic organism, tuberculosis of the skin, or

---

New York State Journal of Medicine, p. 273, 1901.

[illegible] These facts, taken together with the [illegible] [illegible] after treatment, suggest that cancer is produced by some living parasite, and also that the radiation from [illegible]—probably the x-rays—interferes with its life." It would be strange, indeed, if after all these years of groping in the dark the x-ray should come in to help illuminate the darkness in this roundabout way. And still it has happened in the history of medicine that the nature of an ailment has been agreed upon long before the laboratory has proven adequate to unravelling its mysteries.

While it is not essential that the nature of cancer more than any other disease should be known in order to treat it successfully, still it is here, as always, highly desirable.

Science demands exact knowledge, and the public is not yet in that frame of mind which will permit it to accept the Christian Science dictum that cancer along with almost all else is an illusion.

The nature of epithelioma being still unfortunately an x-quantity, or rather quality, it seems not inappropriate to discuss an x-method of treatment for its eradication.

Phototherapy cannot be considered a new method. Indeed, treatment by light is almost as old as light itself.

Still, the impetus it has received during recent years, since Finsen devised his apparatus for concentrating sunlight and electric light, and since Röntgen discovered the peculiarly penetrating rays generated in a Crooke tube, when stimulated in certain definite ways by electricity, have caused observers throughout the world to direct their attention to this form of treatment. Leaving for another time any attempt to discuss the beneficial influence upon skin diseases in general which the *x*-rays may possess, and with which I have already had some favorable experience, and without going largely into the question of apparatus for their production, I will invite your attention to the questions: (1) Should the rays be expected to prove beneficial? (2) Have they so far proven beneficial? (3) In what manner do they exert any beneficial influence or action? (4) How should they be applied? (5) What are the dangers? Seeing, as we have, that the tissue composing epithelial overgrowth of the kind under consideration, is analogous to embryonal structure, being made up of molecules or cells of unstable nature, it is readily conceivable that strongly penetrating rays which have been shown to possess the power to alter tissue of this kind would here find a decided field of usefulness. It is interesting and instructive in this connection to trace the development of *x*-ray skin-therapy from the accidentally produced alopecia, which led Freund, in 1897, to apply the rays in hypertrichosis, and later induced Schiff to try the method in lupus. Success in the latter naturally led to a trial in cutaneous cancer, whose tissue is so analogous in structure.

Furthermore, the rays have been demonstrated to exert a marked effect upon epidemic structures of the normal skin, causing erythema, followed by scaling or pigmentation, changes in the nails, falling and blanching of hair, or atrophy, and, in rare instances, superficial ulcerations of a most persistent nature, showing decided changes in the true skin and subcutaneous structures. That the rays penetrate all structures of the body, and, if they possess any curative power, are capable of exerting it, where previous methods might fail, is likewise in their favor. Again, brought face to face with cancer which has passed beyond a certain point, we have hitherto stood powerless, and have been able only to exercise our skill in alleviating pain, and making the patient's exitus as little distressing as may be. We, therefore, hasten to take up for these cases any method which offers reasonable chances for success.

In order to answer the first question fully, we must pass to the second. It was my privilege in June, and again in September of last year, to observe some of the results obtained by my friend Dr. William Allen Pusey, of Chicago, in several cases of carcinoma of the skin. The gratifying results in the patients seen in June led me to adopt the x-ray treatment upon my return to this city, and those I have observed subsequently in his practice and that of others, together with the reports scattered in medical literature, encourage me to persist, although the time has been too short for personal observations of a very convincing nature.

Besides, I have been unwilling to confine myself to exclusive x-ray treatment in my own cases, believing it not to have gone as yet beyond what we may call the experimental stage, and knowing, as I do, that we possess in certain caustics, properly applied, a quick and effective means of destroying many cancerous growths. I have therefore followed the plan of using first the methods with which I am familiar, and then giving the patient the benefit of all that the x-rays may possess for good in searching out germs or cells which may have escaped our efforts or been beyond the field of operation. Thus the rays act as an after-cure and prophylactic measure, and I strongly advise them after operation with the knife or caustic. In strictly inoperable cases I would not hesitate to use the rays alone, but, having at present no public service, I must depend upon my private practice and the experience of others in reaching a final conclusion. I have thus far treated six cases of epithelioma—one upon the chin, two upon the nose, one upon the finger, one upon the forehead, and one upon the cheek. Four were recurrent cases and one primary. One disappeared from observation; the others have done well, and might be considered cured, but all are still taking ray treatment, and I trust will continue to do so for some months. Besides these cases, I have observed a number of others, and have seen a number of times, in consultation, a gentleman with an extensive recurrence, in whose case the *x*-ray has been practically the only form of treatment applied. This extensive growth has decreased nearly one-half in size, and the general condition has improved, encouraging us to persevere in it.

The patient referred to, who had ceased treatment, did so, I believe, because I advised excision of a mass of nodes in the axilla, believing the cure would be more rapid if the rays were applied subsequent to operation. Another case was lost in like manner because operation for recurrence in the lymph-nodes of the neck after lip cancer was suggested as a prelude to *x*-ray treatment. If a patient absolutely refuses operation in such cases, it is justifiable to proceed with the *x*-rays alone, just as in inoperable sarcoma.

At the meeting of the British Medical Association in August last, an interesting discussion took place upon this new method in connection with that by the Finsen rays, and several speakers advocated an association of the two plans. The reaction after the Finsen occurs, according to Blacker, in four or five hours, while that from the *x*-rays varied from five days to several weeks. My own experience has been that there may be no reaction, strictly speaking, at all.

Sequeira had treated forty-five cases of rodent-ulcer by *x*-ray with most encouraging results. Recurrences were frequent at the margins, but these were readily dealt with. Jamieson had seen decided benefit in two cases. Stenbeck reports one success; Beck, one in melanosarcoma. Here there was apparent local cure, but in metastatic recurrence the patient died. Williams in his book gives reports of two lip cancers, one on the hand, one on the eyelid, and two rodent ulcers, which were improved and caused to heal over. Others might be mentioned. Dr. Pusey has written me of successes in sarcoma, which he will shortly publish.

The question as to how the rays act is as interesting as it is difficult to answer. I think, however, it may be definitely stated that the belief held by some that it is necessary to produce a so-called "burn" is erroneous. I have witnessed definite beneficial effects without any sign of such irritation. Pusey has demonstrated that a cure can be effected without any suspicion of this effect, and I have seen it in my own cases. If this were not so, the caustics already in successful use would scarcely warrant us in introducing another much more slowly acting cautery. Kümmell says healing is surer the less the skin is injured. Some consider that the ray has a specific action, others that it is electro-chemic or tropho-neurotic, and some, again, that the bactericidal action is the most important. As these points have not been decided, and as I am incapable of deciding them, I will leave their solution to others. Experiments so far have seemed to show that the bactericidal influence of the ray-light is slight, though Rieder has recently found that in culture-tube experiments bacterial life seems to be checked.

Effects noted upon an open ulcer are usually a lessening of exudation, if it has existed; a drying up and glazing over the parts, and desquamation about the margins, from which cicatrization takes place. Sometimes there is a suppurative breaking down of neoplastic tissue.

In an old gentleman with an epithelioma of the nose of many years' standing, which now appears to be cured, treatment has been carried out by Dr. F. N. Wilson and myself; the ulceration has healed, and the whole surface has desquamated in a manner not before seen after other treatment. In view of the tendency to multiplicity of tumor formation in his case (epitheliomatosus), I have advised the rays to be continued for some time as a prophylactic measure.

Now, as to the proper application of the rays, only general rules can be made. As we possess no satisfactory way of measuring the intensity of the light, and as we never know surely the susceptibility of the individual, it is wise to be cautious in several directions. The first sittings should be short, with the tube not too close. The parts other than those to be operated upon should in all cases be protected. I employ various devices. A band-box of pasteboard cut out to accommodate the parts and covered with extra thick tin foil, containing a large percentage of lead. Or better, perhaps, a thick lead mask put on over a gauze mask and bound to the parts. These I ground by running a wire to the chandelier to carry off the electricity. I have also suggested a funnel-shaped metallic cone, into the flare of which the active area of the tube is inserted, especially for mouth, throat, uterine and rectal work. It has been advised to cover exposed parts with vaseline. It is well after the first sitting to wait a week before proceeding with daily applications, and the time of exposure can be gradually lengthened. If signs of dermatitis or decided erythema show themselves, suspend treatment until these effects have subsided. As to the distance of the tube from the part treated, we must be governed by the patient's susceptibility, length of treatment already carried out, length of each exposure, hardness or softness of tube, nature and size of the diseased area, and the operator's confidence born of experience. Hopkins advises a distance of twelve to thirty inches, while Pusey says about two inches for skin cancer work. Between these limits, operators in general vary the distance from one or another consideration. Most of my work has been done at rather close range—three to five inches. With the glass at an inch or less from the skin, as I have at times used it, the anode is still several inches away, when a large tube is employed. The nearer the tube and the longer the exposure, the greater is supposed to be the danger of "burn." Still, in such a severe affection one might be justified in taking a certain chance, and if the "burn" affects the diseased area alone, I am not sure that the cure would be delayed in consequence. At times there seems to be a marked lessening of pain in the part after the ray treatment, and this effect has been noted in other conditions such as articular rheumatism, gall stones, etc.

The time of exposure ranges between three and thirty minutes. The usual sitting being fifteen or twenty minutes. Tubes exist in great variety. The Monnell type is a good one. It should be in perfect harmony with the kind and power of the electrical supply. Those for static machines differ somewhat in their make from those for coils.

There is a water-cooled tube, the target being the end of a receptacle projecting into the tube which can be filled with cold water. There is also a rather new tube with a funnel-shaped anode.

The characteristic of the funnel tube is the shaping of the target like a funnel, so that the rays are only given off in a comparatively restricted cone, instead of being widely diffused, as in the case of an ordinary tube. The prevailing opinion seems to be that a tube, to do the best work in skin diseases and cancer, should run low, *i. e.* that the vacuum should not be too attenuated, the tube thus running on about two or three inches of spark on the outside and giving poor penetration; *i. e.* if the hand is held before the fluoroscope, you should get a dense black shadow of the hand without differentiation of tissue and bone. To exhaust a tube so that it will do this, is a difficult matter, as, when in this condition, the tube seems to be more or less unstable, and tends either to run down altogether, or more generally to run high, and give good pictures. To hold the tube at the required point, a small offshoot is added containing some material like phosphorous pentoxide, having the property of absorbing gases and of giving out the same when heated. By arranging a spark-gap, which is adjustable, in a shunt-circuit, so that part of the discharge can be sent at will through this vapor-bulb, it is possible to drive out sufficient gas from time to time to lower the vacuum to the desired point.

Now, as to the source of electrical energy and choice of apparatus, much depends upon where the rays are to be used. If in an institution or office, my choice would be a static machine. If in a patient's house, a coil is obviously more practical, though I am inclined to believe less suited to therapeutic uses. The static machine gives a steady flow of current of high voltage, and there are no accessories to confuse.

Williams states his preference for the static machine for therapeutic uses of the rays. Others prefer the coil. Excellent coils are now made in this city. As to strength of current, Freund advises an electromotive force of 12 volts, with 1.5 ampères resistance, and a spark-length of 30 cm., or about twelve inches.

Williams has employed 220 volts, with 2 ampères and 35 cm. spark-gap, without causing dermatitis. The ray is always the same, no matter how produced, and this is a point which is not always appreciated. Whether our electrical apparatus is static, high frequency, or induction coil; whether large or small, powerful or weak, if it produces an x-ray that will do the work, i.e., if there be sufficient current and sufficient spark-gap, the ray is as good as any other ray produced in any other manner. Large coils develop more energy and are capable of exciting larger tubes, but that is all. In therapeutic work we do not want too "strong" a tube, if such a term might be permissible. It should not be too penetrating.

Turning to the final question, "What are the dangers?" I may say I believe them to have been overestimated. I saw several years ago a number of severe ulcerations from skiagraphy (usually after long exposure and without a protecting shield), and have since had numerous cases of loss of hair, dermatitis, and persistent skin and nail changes brought to my notice, but almost always due to incautious exposure. I think these cases are growing fewer in spite of the much more extensive use of x-rays. Unquestionably much damage might be done by this method in incompetent hands, and quacks may bring it into some disrepute, but the public's present fear of the rays should be allayed, rather than intensified, by the cautions so freely given out by those without experience. Before closing, I wish to say a word about methylene-blue applications coincidently with x-ray treatment. It has been stated that while the rays are being used no powders, such as aristol, iodoform, etc., should be applied, as this interferes with the rays' action.

I have applied the blue solution, which I have used so long and so successfully in a great variety of dermatological conditions, in a number of my epithelioma cases under treatment by the rays with seeming benefit. The only way, it seems to me, this could interfere with the rays' action would be by preventing their penetration. To test this point, I painted one finger of my own hand with a thick coating of blue, and examining the hand with the fluoroscope found that the bones of this finger were quite as distinct as those of the other fingers, and the shadow of the soft parts was not intensified. In placing a piece of board, one-half of which has been deeply stained with the blue, upon the screen, neither portion is visible. To my mind this disposes of the question, so far as methylene blue is concerned.

As Finsen has shown, a blue solution interposed between his light and the part operated upon shuts out or absorbs the ultra-violet or chemical rays which have the irritating or burning quality. In using concentrated sunlight and other forms of phototherapy, I have for some time been painting the pathological surface with methylene blue instead of using a blue solution at a distance from the body.

In lupus this plan I have found to act well when the *x*-rays were used, and even if the blue paint does not shut out any burning rays emanating from a vacuum tube, it does no harm, but, on the contrary, gives the patient the benefit of an added form of treatment not devoid of value. Stein made the claim in the *Electrical Review* of November 18, 1896, that burns are caused, not by the x-rays, but by ultra-violet light coming from the tube. If this comes to be proven, the plan I suggest ought to prevent the danger from so-called burning.

Other theories are those of Tesla, that the ozone generated upon the skin does the injury, and Trowbridge claims them to be the effect of electrification.

Whatever may be the cause of the dermatitis at times produced, it would seem that properly arranged and grounded screens, marks, etc., the use of such a funnel-shaped appliance as I have suggested for keeping the rays away from all but the parts under treatment or observation, and perhaps the application of methylene blue to the parts to be operated upon, might remove all danger.

[illegible] East Thirty-third Street.

REPORT OF THE COMMITTEE ON SANATORIA FOR CONSUMPTIVES.

PRESENTED AT THE STATE CONFERENCE OF CHARITIES, NEW YORK, NOVEMBER 21, 1901.

By JOHN H. PRYOR, M.D.,
BUFFALO, N. Y.
CHAIRMAN OF THE COMMITTEE.

There are many reasons why the report of your committee should consist of a presentation of important facts and an appeal for interest and support of somewhat new projects. During the last few years the subject of tuberculosis has been much discussed, and no question of a social, economic, medical, and charitable nature is of such vital importance to-day as the problem of the prevention and care of the victims of that disease.

The poor sufferers from so-called consumption, after years of appalling neglect, have aroused the pity of humanity, and stimulated a desire to attack a cruel wrong which ignorance and apathy have allowed to oppress a vast army of dependents. In the course of time this meeting of the State Conference of Charities and Correction may become historic, as marking a distinct epoch in the extension of its aim and work. At last, the saddest thing in the world has become the subject for serious consideration at a meeting devoted to the discussion of enlightened methods for the suppression and relief of suffering and distress.

When this body reached the decision last year that the consumptive and his woe should be recognized, as affording a new field for scientific and humane investigation, a grand stride in progress was made, and the announcement brought a feeling of deep gratitude from those who have struggled and fought in the long crusade against the greatest scourge of humanity.

About eighteen years ago Koch discovered the bacillus and the cause of tuberculosis. The facts that the disease was infectious and communicable were established. Prevention promised to be successful by simple measures, and the belief and hope that the disease could be eradicated were accepted by the progressive element of the medical profession with great enthusiasm. Sufficient time has elapsed to examine the results of a prolonged attempt to diminish the prevalency of the disease. Undoubtedly the death rate in proportion to the population has declined. In some localities a decrease of 30 per cent. is claimed. Many times this decrease is ascribed to special efforts aimed at tuberculosis, and it is offered as proof of their successful employment.

There seems to be a tendency to forget that during the last decade civilized countries have felt the results of the greatest wave of sanitary reform known in history. The general death rate declined in a marvelous way. By comparing the figures for 1880 and 1890, it will be found that many European and American cities lowered their death rate from 30 to 50 per cent. In some American cities the death rate has decreased from 22 per cent. to 30 per cent. in the last five years. The death rate from pulmonary tuberculosis shared in that decrease, which was due to improvements in sanitation and hygiene, particularly among the poor. A scrutiny of the mortality returns in this State reveals the fact that the principal decrease has occurred in New York City, chiefly among the female population. This was largely due to the work of Biggs and others in checking the spread of the disease in the tenement-house district. The best example of brilliant results attained by direct and special methods are those reported by Biggs, and the disgraceful conditions of overcrowding, lack of sunlight, and fresh air, which prevail in these compulsory homes of the poor, afford the chief opportunity for attack and triumph.

The tenement becomes infected, and herding together encourages the spread of the germs of disease, while vicious surroundings and insufficient or improper food promotes susceptibility and a tendency to succumb. To-day the chief penalty of tenement-house life is tuberculosis. Most of the poor dwellers show evidence of tuberculosis during life, or at the autopsy. Segregation, destruction of expectoration, and disinfection of contaminated homes will eliminate the foci of disease so strikingly depicted by Flick of Philadelphia and Biggs of New York. This work can be done by a board of health not poisoned by political taint.

The new tenement-house laws, if made operative, and clean machinery supplied to enforce them, will have a decided and lasting effect upon the principal cause of illness and destitution.

While prevention along general and special lines has diminished the number of deaths, in proportion to the population in this State caution must be exercised before accepting frequently repeated fallacious statements. To say that the efforts to eradicate tuberculosis have fulfilled expectations and will win in time is to approach dangerously near exaggeration and a careless promise. The present campaign in this State lacks system, uniformity, and thoroughness. Protection is at best partial or very inadequate. At present the State Board of Health is attempting to make a census of the consumptives with a view to considering what may be done in the way of prevention and care.

The prediction is fair that no more than an approximate estimate can be obtained. Each physician is requested, not compelled, to report the number of cases under his care. Compliance is optional, and should the advanced, easily recognized cases be reported, a large unknown number of incipient cases will escape.

By collecting the reports of many hospitals, it is found that about 25 per cent. of autopsies reveal evidences of healed tuberculosis. These cases, with few exceptions, are unsuspected. Again, there is a decided and growing tendency to conceal the affliction of tuberculosis, for reasons given later. We already possess a method of estimating the number of consumptives in this State, by computing the average duration of the disease, from the figures supplied in death certificates.

Each year more than 14,000 human beings perish from tuberculosis of the lungs alone in New York State. Assuming that the average period of misery is only two or three years, there must be 28,000 or 42,000 victims. The latter figure is probably more correct, because those best informed claim at least 25,000 consumptives for New York City. But what earthly or heavenly difference will it make in discussing plans for attack or care whether we have a few thousand more or less in this pitiful army marching to the grave? No mysterious. ingenious remedy has been discovered which will apply to a mere 25,000 and prove impracticable for twice the number.

For years the purpose has been to educate the public and create sentiment before remedial action can be taken. Now, what has been the result of education? An awakened interest and readiness to welcome rational procedures, which are not supplied. The public has been taught certain facts with great benefit, and some fallacies which are misleading and cruel. The cry has been: Tuberculosis is infectious and dangerously communicable. It is unnecessary and easily preventable. Note the words, "dangerously communicable," and try to measure their meaning. Are we to understand that it is highly communicable from one person to another, or only slightly so? Why not admit that it is infectious and scarcely at all communicable, if simple precautions are adopted? The danger of contracting the disease from the poor creature, who suffers through no fault or crime, has been exaggerated until we have an epidemic of hysteria or phthisiophobia. The unfortunate has had new torture added to his misery. He has been denied admission to hospitals, discharged from employment, and even lost the pleasures of friendship on his sick-bed. If it be true that prevention is easy, why add more hardships? There is no place where a person can enjoy greater immunity from tuberculosis than in a hospital or sanatorium devoted to the treatment of consumptives. The rule is that no servant, attendant, nurse, or physician develops the disease. The time has arrived for the physician and the laity to modify certain extravagant views, and learn to be kind and reasonable, not ultra-scientific and harsh. In this country a quarantine has been established against tuberculosis as a *dangerously communicable* disease. For some years the advanced consumptive has been denied admission as an undesirable citizen—an act most proper and justifiable, but the early cases will not be observed and checked, and a precedent has been established. If the threat of some Western States to follow this example should be fulfilled, a new phase of an appalling problem must be confronted. It is right that far-away States should resent the unloading of the hopeless, poor consumptive upon them, and one good result of recent protests will be the enforced provision of rational treatment near the home. This means an undertaking of such magnitude that the alleged facts. "the disease is unnecessary and easily preventable," are offered in support of a policy of gradual eradication. There can be nothing gained by hugging a delusion that fewer people die from pulmonary tuberculosis now than formerly. Remember that a smaller percentage of the population succumb, but the population has increased and continues to increase rapidly. The actual number of deaths grows slowly each year, and we have reached and will probably soon pass the mark of 14,000 per annum. Furthermore, there are several well-known causes for errors in the returns, and the number reported is beyond all doubt much too low. As the result of some persecution, the consumptive and his family beg to have the truth untold, or evaded, on account of hardships and the difficulties surrounding life, health, and industrial insurance. But the statistical evidence shows that pulmonary tuberculosis causes 11 per cent. of all deaths each year, whether the general death rate is high or low. That is greater than the mortality from all other infectious diseases combined, and about equal to the loss of a city population each year. The extent of the ravages of all other forms of tuberculosis is not known. People have become accustomed to the fearful calamity, and when aroused for a moment, shudder and shrink. The somber procession receives recruits with remarkable accuracy, and everlastingly moves on to the tomb, while a few toll the iteration, "Help the consumptive; he is neglected and can be saved." Sentiment is a strange thing. Imagine fourteen regiments of infantry marching away to battle and every one doomed to die.

The devastation of wars, though small in comparison, seems so real and tragic, while the slow, unceasing destruction of multitudes by a lingering illness fails to stir wide sympathy or public interest. So long as pulmonary tuberculosis is responsible for more than 11 per cent. of all deaths, and this rate bids fair to be continuous under present conditions, it is plain that we cannot depend upon prevention as now employed to compel a tragedy so mighty that epidemics sink into insignificance. When the nation or the State assumes control of broad and adequate methods of protection and system, uniformity, and co-operation are thus assured, the outlook will be brighter.

Unquestionably, the scientific plan should be to attack the cause, and one essential factor in the combat must be provision for proper care. The poor must be encouraged to leave their homes, not alone to prevent infection, but to obtain relief from suffering and a chance to improve. Special hospitals should be provided for advanced patients and the dangers of communication avoided. This is of transcendent importance in the tenement districts and the crowded small homes of the poor, where ignorance and necessity combine to make precautionary rules difficult to obey or enforce.

The desire to segregate and instruct is the chief plea for the establishment of special hospitals for advanced or incurable cases, but they should not be the only reasons given for a stern demand or strong appeal. This big class of sufferers must have a place to go and rest when they can toil no more and the struggle for existence is over.

In New York City the need for such special institutions is imperative, and co-operative endeavor along the lines pursued by societies for the prevention and care of tuberculosis should be encouraged. These societies have exerted a powerful influence elsewhere, and this city represents a large field for fruitful work. But any argument in favor of attacking causes, any appeal for rational care, or any denunciation of inaction reaches a culmination when we consider the neglect and mismanagement of the early or incipient case. That is the blot upon our civilization. That is the disgrace which brings a blush of shame for existing conditions, unequaled in the history of brutal indifference since the insane were emancipated and released from the cell and the shackle.

Then ignorance was the excuse, but to-day knowledge is the indictment. We know that incipient tuberculosis is curable, and the well-to-do can seize the opportunity to recover. The vast majority of consumptives die simply because they are poor and no provision is made for curative treatment. The pitiable conditions surrounding the consumptive make his misfortune and distress unique. And the antiquated methods of help constitute a strange anomaly in our system of charities. Any other sufferer from disease, be the malady what it may, can obtain proper medical skill and care. The consumptive alone has no chance for his life. Only one form of treatment promises anything, and that involves rest for a time, where the air is pure, with plenty of good food and special education with discipline.

The consumptive is the natural result of overlooked or neglected tuberculosis, and the very name perpetuates widespread misconceptions.

Tuberculosis is one thing, consumption or phthisis another. When tuberculosis is detected early, the tendency to recovery is greater than that of any other chronic disease. It is when the disease is not arrested that other germs appear, become active, and develop mixed infection with the manifestations grouped under the name consumption. The nomenclature must be changed, and terms employed which denote progressive ideas. What the public knows as a consumptive is the victim marked for death; but the physician can recognize the tuberculous case at a time when 70 per cent. of the victims might be saved, if he, like other human beings, could secure enlightened aid. The vital points are the early diagnosis and prompt relief. Now there is nothing gained by telling the poor consumptive that he has a disease which sanatorium treatment would arrest, when it is known that such help is impossible. That announcement is a death sentence and a confession that all hope is denied.

Yet assistance which costs just as much is given when it is too late, and destitution drives the dependent to the last resort.

The establishment of sanatoria for those suffering from incipient pulmonary tuberculosis would prove of incalculable benefit. The infected individual could be removed before becoming a source of danger to others, and undesirable progeny prevented. Education in the way of special hygienic habits is made practical and the idea that tuberculosis is curable can be disseminated.

Statistics show that the results are brilliant. Those who do not recover, experience improvement or temporary arrest of the disease, and return home with special and valuable instruction. The percentage of recoveries reported by any sanatorium will depend upon the care employed in selecting truly favorable cases.

At present much complaint is heard from those connected with sanatoria for consumptives because the cases sent arrive so late. When appendicitis was called inflammation of the bowels, and was usually fatal, there was little blame; but now failure to notice appendicitis until all chance for successful treatment has been lost is apt to incite criticism.

Under the present system of economic mismanagement, the tuberculous are allowed to struggle along until they, and usually others dependent upon them, need financial aid. Now, register the fact that the great proportion of consumptives die between the ages of 18 and 32 years, or at the time of life when education or training and youthful strength promise the highest degree of continued production and earning power. It is the age when others lean upon a bread-winner. Nothing is done to prevent destitution, and the sickness ends in irretrievable loss, when a few months' stay in a sanatorium would return the stricken individual to the ranks of workers.

Let us roughly estimate the loss of wealth due to consumption in this State. In Germany a human life is valued at $1,500; because, by some statistical method, it is found that it costs that amount to rear and educate a citizen. If an American is equally valuable to the State, the loss is $21,000,000 per annum. Now add the expense for illness, the amounts contributed for relief to the dependents, and the ultimate cost of degeneracy in the offspring. The whole sum is far greater than the cost of our State government. Much, very much, of this needless drain can be saved by early care. That is the surest and the kindest method for diminishing the prevalency and the death rate of tuberculosis.

The old do-nothing plan means loss and expenditure, misery and death. The new way will mean effectual help for the sufferer and possible aid for a family until health is restored.

Once more, let me reiterate the sentence which I have used for five years at Albany: "Take care of the consumptive at the right time, at the right place, in the right way, until well; not at the wrong time, at the wrong place, in the wrong way, until dead."

The hopeless, obsolete plan costs more than the scientific, successful one, which should appeal to charity workers, who are baffled by the problems of pauperism and distress which accompany and follow tuberculosis.

The incurable consumptive receives a term of hospital relief fully as long as that required in early sanatorium treatment, and the cost per week at the best sanatoria is decidedly less than the average expense in New York hospitals.

Admitting that proper care of the incipient tuberculous is a necessity, what scheme can be adopted to inaugurate and extend the reform movement? The duty falls upon the State, municipality, and private philanthropy. There are 14,000 new cases every year, and the task is stupendous. In fact, the magnitude of the effects of long-continued ignorance has been the chief obstacle to overcome. It is so natural to whimper that any attempt will only benefit a few, but if ever a good, lusty fight against big odds was worth while, the battle now on fills all requirements.

Every life saved removes one consumptive from the disgraceful total, and if, in the course of time, 1,000 people a year could be removed from the ranks, the army will disappear from lack of recruits and not continue to grow in numbers. Some years of thought, study, and patient listening to many objections have strengthened the convictions that the State should lead and stimulate supplementary action. The tuberculous poor need unusual and peculiar relief, which all cities and counties cannot supply, and by providing an institution of special character, at a suitable place, results and methods can be demonstrated, an object lesson taught, and ideal prevention attained. After a long campaign, money has been appropriated for a State hospital for incipient consumptives, to be located in the Adirondacks. It is to be built and managed by the State, but the expense of maintenance is to be borne by the counties sending patients to the institution.

In time, an opportunity will be afforded to investigate many questions of a clinical nature, and general interest will surely be awakened by an innovation which means so much to humanity. The agitation for the establishment of one State institution has had a pronounced influence everywhere. When the project first won attention and discussion had become serious in this State, Massachusetts acted quickly and built the first State sanatorium in this country. Connecticut has followed, and at present similar legislation has been urged or is contemplated in twelve States.

There is no good reason why certain counties or municipalities should not follow the example, and establish sanatoria in localities where excellent results can be obtained. In 1889 the Henry law was enacted, authorizing cities of the first class to establish hospitals for consumptives beyond their city limits. The purpose of this measure was to enable New York City to establish such institutions, but thus far nothing decisive has been accomplished in this direction. Progress may be slow, but the time will come when people will wonder that the introduction of common-sense management involved years of strenuous labor. Why the attention of philanthropists is not directed to this opportunity for accomplishing lasting good seems most mysterious. Gifts and bequests reach all classes of the afflicted poor, except the consumptive. Yet no unfortunate is more worthy, no form of help more practical, and no known results more far-reaching. The grim fact that thousands of unnecessary deaths occur every year among the poor in a State rich beyond comparison must be due to a lack of appreciation or ignorance of the hideous truth. In European countries, and especially in Germany, great progress has been made. There are more than sixty sanatoria for poor consumptives in Germany, and the number is increasing at the rate of five a year. Next year, accommodations will have been provided for over 12,000 patients. The results are uniformly encouraging, and the decrease in prevalency is remarkable. Most of these institutions are supported by government insurance companies, and the investment pays because the patient recovers or improves, and the duration of his earning capacity is lengthened.

While the introduction of this form of insurance against illness might not be advisable in this country, it is worthy of study as a prevention of pauperism and a lesson in economy. Germany has initiated and developed a practical plan for accomplishing a reform which remains almost untouched in America. Perhaps some beneficent and profitable change will be brought about by the industrial insurance companies. Now, the undertaking seems improbable, because discouraging financial questions arise under the present rate, but some kind of health insurance will surely be supplied. The development and growth of health insurance in this country have been surprising during the last three years. Protection against illness has been extended until now a large class dependent upon moderate incomes can obtain full opportunity for regaining health, and consumption has finally been included as a risk.

We must propagate the belief that pulmonary tuberculosis is curable during the early stage of the disease. We must teach the people to desire and demand a chance to get well. Let it be known that the hopeless consumptive, emaciated, feeble, and gasping for breath, with the horrid death rattle clogging his throat, might have been saved by science and a little charity. Simply emphasize a few plain truths, and protest against the lack of common sense which characterizes the treatment of pulmonary tuberculosis. The establishment of sanatoria, as an example, is necessary now; but the time is not far distant when the American will awaken from his slumber, and perceive that his country lags so far behind Europe in its appreciation of this one phase of modern thought that it will soon compare with Asia in stubborn, stupid disregard of the greatest question concerning public health. Then prevention and intelligent care will be inaugurated and pushed with zeal and energy which will astonish the world, and a reputation for unparalleled philanthropy will be sustained.

TWO CASES OF GASTROENTEROSTOMY WITH ENTEROENTEROSTOMY DONE WITH THE AID OF THE ELASTIC LIGATURE (McGRAW'S METHOD).

By WILLY MEYER, M.D.,
NEW YORK.
PROFESSOR OF SURGERY AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; ATTENDING SURGEON TO THE GERMAN AND NEW YORK SKIN AND CANCER HOSPITALS; CONSULTING SURGEON TO THE NEW YORK INFIRMARY.

In the New York *Medical Journal* of January 26, 1901, Dr. Theodore A. McGraw of Detroit published a most interesting article on gastroenterostomy by means of the elastic ligature.

He had conceived the original idea of using this means more than ten years ago. He had then experimented on dogs and tried the method twice also on the human subject. He soon abandoned further investigations, giving preference to Murphy's button, which then had just been introduced. The number of disadvantages connected with this otherwise so ingenious service, however, made him again take up the method of his own invention.

His method is briefly as follows:

That part of the gut which is to be anastomosed is stitched to the anterior or posterior wall of the stomach, as the case may be, by a number of interrupted sutures. A fold of the gastric wall is then at its base pierced with a needle, threaded with an elastic ligature, two or three millimeters in diameter, and the needle with the elastic cord returned through the attached coil of intestine at points corresponding with the entrance and exit of the ligature in the wall of the stomach. The cord is passed through the bowel always in the direction of the longitudinal axis of the latter. In passing it through, it is stretched as much as possible. This renders it thin and small, so that it may be easily drawn after the needle. Its subsequent contraction will then largely increase its size and cause it more than to fill the orifice. It will even distend the holes so as to prevent any extravasation of intestinal fluid. The ligature is tightened as much as possible, and the crossed ends secured by a stout silk thread passed underneath and tied on top. The field of operation is then buried by uniting gut and stomach in front of the ligature by another row of interrupted sutures. It is evident that we have it thus entirely in our hands to arrange the width of the opening.

In his experiments upon dogs, Dr. McGraw observed that the puckering of gastric and intestinal wall that necessarily follows the tightening of the ligature flattens out after a few days. In some way the intestine accommodates itself to the new conditions and becomes speedily smooth and shapely. On the third day the ligature commences to cut through. Consequently, feeding by the mouth may be begun at that time.

This plan of operation impressed me as eminently simple, comprehensive, and safe, so much so that, although having been greatly in favor of the use of the Murphy button in this class of operations for the last eight years, I concluded to try it in my next case of gastroenterostomy.

CASE I.—The first chance that presented itself was the following: S. F., a man fifty-two years of age, entered the German Hospital in July last, with all the clinical symptoms of a far-advanced malignant stricture of the pylorus. He was extremely emaciated, having been unable to retain any food for the last two weeks, so that rectal alimentation had to be resorted to. The stomach was greatly distended, the large curvature reaching almost down to the symphysis, and a movable tumor, the size of a hen's egg, was palpable to the right of the median line in the region of the pylorus. The process of washing the stomach took nearly one hour and a half, as the water did not return clear any sooner. In view of the reduced condition of the patient, pylorectomy was contraindicated and gastroenterostomy decided upon. Operation was done on July 17. A large infiltrating carcinoma, involving the pyloric region, but still comparatively movable, was found, the glands of larger and lesser omentum were diffusely infiltrated. Omentum and transverse colon were therefore lifted out of the abdomen; the transverse meso-colon was bluntly divided, its borders being stitched by means of a few interrupted silk sutures to the posterior gastric wall. The upper portion of the jejunum was quickly found, and a coil some seven to eight inches distant from the plica duodeno-jejunalis was attached to the stomach by a number of interrupted silk sutures. Care was taken to place the sutures in such a way as to allow the ligature to pass through the bowel at a point most distant from the mesenteric attachment. A straight Hagedorn needle threaded with the elastic ligature (No. 2 = 2 mm. in diameter) was then pushed through the basis of a fold of the posterior wall of the stomach, which had been raised and drawn forward, with thumb and forefinger of the left hand, at a place about one-half to three-quarters of an inch from the line of sutures. While the first assistant stretched the ligature, I pulled the needle forward with a jerk, after which it followed with the greatest ease. The same was done on the serous wall at corresponding points in the wall of the jejunum. Here, however, I did not dare raise a fold, fearing to pierce the posterior (opposite) wall of the gut. Hence I pushed the straight needle into the lumen of the gut, moving it laterally to make sure that it was in the lumen, and then made it pass out again at the proper distance. Again the assistant stretched the elastic band when I was ready to pull it forward. Fully five to six centimeters of tissue in length were included in the ligature. Then it was tightened as much as possible, the first assistant having a piece of braided silk, in a direction parallel with the longitudinal axis of the stomach, ready below the crossed ends of the ligature in order to secure them properly. At the moment that he tightened the knot, the one end of the elastic ligature tore, fortunately distal but close to the silk knot. There was some discussion later on among those participating in the operation whether the ligature tore immediately before or after the tying of the silk knot. At any rate, it seemed to me sufficiently tight to leave it in place. A second knot was placed on top of the first, with some difficulty on account of the shortness of that one end, and the anterior row of interrupted silk sutures added, thus entirely burying from view the field of operation.

The work had appealed to me as so extremely simple, and the patient had stood the operation so nicely, that notwithstanding the great necessity of speed in this case, I nevertheless decided to add enteroenterostomy to avoid the much-dreaded "vicious circle." I therefore repeated the same procedure on the afferent and efferent parts of the gut, the only variation being that a continuous instead of an interrupted silk suture was employed to unite the two parts of the intestine behind and in front of the ligature. The same silk thread was used for the continuous suture all around the anastomosis. I regret that this additional anastomosis had not been prearranged. The distance between gastroenterostomosis and enteroanastomosis was, therefore, shorter than it ought to have been. According to Mieulicz this distance should be at least 15 cm., while in my case it thus happened to be but 5 to 6 cm. After the two anastomoses were completed, the parts were returned into the abdomen and the wound closed by silk sutures, which embraced the entire thickness of the abdominal wall. During the first eight days the patient made an excellent recovery; he was put on nutrient enemata and repeatedly received 500 to 1,000 c.c. of saline solution in the shape of hypodermoclysis. On the third day feeding by the mouth in very small doses was begun. He seemed to relish the food and absorb it, as was demonstrated by the amount of urine voided, which almost regularly was above 1,000 c.c. within twenty-four hours. On the fifth day larger doses were allowed, from two to three quarts of liquid being given. The new anastomotic opening evidently worked very well, inasmuch as the patient before operation had regularly vomited large masses of the liquid diet that had been allowed him. Convalescence went on undisturbed until on the ninth day he vomited at least a quart of liquid at one time, and this he repeated on the eleventh day after operation. On the fourteenth and fifteenth days his general condition became rather alarming, so much so that I was almost sure the much-dreaded "vicious circle" had been established in spite of the entero-enterostomosis, or rather, as I tried to explain it, owing to the undue proximity of the two anastomotic openings. We then performed very thorough lavage of the stomach, a measure which I have often employed in cases of severe vomiting after gastroenterostomy and the result of which has almost invariably been very gratifying. Although the patient vomited again three times on the same day and almost continuously two days later, the turning point of his trouble, nevertheless, appeared to have been reached, for, commencing with August 6, or the twentieth day after the operation, emesis ceased entirely, and thereafter the patient made an uninterrupted recovery. As the patient had to expect rather unsatisfactory attendance at his home, he remained at the hospital longer than was necessary. On leaving, in the early part of September, he had gained twenty pounds. When weighed again two months later, he had gained another ten pounds. He still complains of occasional pain in the epigastrium, and on this account his family will not let him resume his former vocation, that of a shoemaker, since it necessitates his bending over his work. Otherwise the patient is able to eat everything, and as much as he wants, without the slightest discomfort. He was presented before the New York Surgical Society November 13, 1901.

In reviewing this case, it must be regretted that there are two points that tend to make the immediate result of this operation appear less successful than one generally may have a right to expect. The first is the breaking of the elastic ligature at the most important moment during the entire operation, viz., the tying of the silk knot; and the second, the close proximity of the two anastomotic openings unavoidable in this case.

The possibility of a recurrence of these accidents was successfully guarded against in the second patient who was soon presented.

Case II.—This was the case of a gentleman under the care of Dr. Max Einhorn of this city at the Post-Graduate Hospital, a syphilitic who had recently developed all the symptoms of a serious gastric disease. Although the presence of gastrectasis could not be proved, chemical analysis clearly pointed to ischochymia. Gastrodiaphany showed a dark area in the upper part of the stomach, the illuminated zone extending principally to the left side of the linea alba in the region of the umbilicus. At times the stomach appeared rather bloated, and then a mass corresponding to the dark area just mentioned could be palpated. Anti-specific treatment having given no result, it was concluded that the trouble must be of malignant character, requiring laparotomy. I was invited to perform the operation and did so on August 24, 1901. The stomach appeared very small and contracted. The pylorus underneath the liver presented a large hard infiltrating neoplasm which extended over the entire lesser curvature. Total extirpation of this mass seemed impossible, since not even the larger curvature of the stomach could be conveniently pulled into the abdominal wound. Posterior gastroenterostomy had to be abandoned on account of the shortness of the mesocolon transversum. I therefore did anterior gastroenterostomy again with the help of the elastic ligature. This time I selected a portion of the jejunum fully 30 to 40 cm. distant from the plica duodeno-jejunalis. Same as in the first case, the coil selected for approximation, having been shut off tightly at either end with intestinal clamps, was attached to the stomach with a number of interrupted silk sutures; then an elastic ligature, three millimeters in diameter, was pulled through in exactly the same manner as before described. A double knot was tied, and each time secured with a silk ligature. This time it did not break, though it had been stretched as thoroughly as possible. Then the field of operation was buried by uniting the two parts in front of the anastomotic opening with interrupted silk sutures. Thereupon enteroenterostomy was done, at least 15 cm. from the field of operation, with the same size ligature. It was barely made one-half the length of the other anastomosis; continuous silk suture was used in front and behind. The parts were dropped back and the abdomen closed. The patient made a most satisfactory and uninterrupted recovery. He was kept on nutrient enemata for three days, small doses of water by mouth being begun on the third day. He did not vomit once after the operation; the wound closed by primary union, and he left the hospital in the early part of September, much improved in body and mind. Since then the patient has steadily gained in weight and strength, and now weighs within ten pounds of his normal weight.

In the course of this second operation, I was again much impressed with the simplicity and safety of the method.

In regard to the ligature itself, I shall continue to use that 3 mm. in diameter, if I do not change to one 4 mm. thick. If a straight Hagedorn needle with a large, or, better still, split, eye is employed, the ligature is easily threaded. If a needle with closed eye is used, threading will be facilitated by trimming one end of the ligature with a pair of straight scissors so as to make it taper; as long as the mere tip passes the eye, it can be easily grasped by means of a pair of forceps, stretched and pulled forward. McGraw has since had molds made for the manufacture of ligatures with a tapering end. This, of course, as he states, "facilitates the insertion of the cord in the needle and enables the surgeon to draw it through a very small aperture without injuring the tissues." Yet, I consider it a slight drawback to the otherwise highly commendable procedure to have the elastic bands especially prepare. I certainly have seen no difficulty, as just explained, in threading as well as in pulling the ordinary ligature through the gastric or intestinal wall so long as the assistant thoroughly put it on the stretch.

In the Medical Record of October 5, 1901, McGraw publishes a second also very interesting article on this subject, entitled, "The Use and Limitations of the Elastic Ligature in Intestinal Surgery." In it he replies to the objection made to his method, namely, that the anastomosis is not an immediate one, but ensues three to four days after the operation. He states that he considers it highly probable that in cases where the stomach has been the subject of operation, more nutriment is absorbed from high enemata than from any food that could be introduced into the upper portion of the bowels. He also shows that the fear often expressed, "that the ligature will not certainly accomplish its work, is absolutely without foundation if the operation is properly performed," that is to say, if first a firm, hard, round rubber cord of the necessary size is used; second, not too small an amount of tissue of the wall of the bowel is included in the loop—"the larger the amount . . . the quicker and more certainly will the ligature perform its work;" third, if the rubber cord is drawn as firmly and tightly together as possible, and fastened by a silk thread, which is tied around them. In a large number of operations on dogs, in whom the intestine is much thicker than in man, McGraw never has met with a failure.

Up to the time of publication of his first article (January, 1901), McGraw had made use of the elastic ligature in gastroenterostomy on the human subject five times, twice in 1891 and three times in 1900. Two of the patients were extremely weak, when operated upon, and died a few hours after the completion of the operation. Two died fourteen and fifteen days later, respectively. Death, however, being independent from the method employed. Post mortem showed a perfect anastomosis in both cases.

With regard to the immediate effect of the elastic ligature, McGraw states that the part of the bowel which is in its grasp does not slough, but undergoes a process of absorption. For when examined at the end of the fourth day after the operation the edges of the orifice, including the mucous membrane, are found closely united, without any raw surfaces whatever. The result is a 'smoothly healed edge all along the opening.'

"When it accomplishes its purpose the small contracted rubber cord passes away unremarked in the fæces."

Whether subsequent contraction with partial obliteration of the orifice, such as has happened after other methods of producing anastomosis, will follow in course of time is as yet uncertain. There surely is no reason, with reference to the procedure as such, to expect contraction to any great extent. No doubt we will soon be in possession of specimens which will demonstrate also in the human being the condition of the anastomosis, made with the help of the elastic ligature, in all its phases.

In conclusion I hardly think I could do better than quote McGraw's own words in his last article referred to. He says the operation, done with the elastic ligature, "is the quickest of all operations for the production of intestinal anastomosis." A few Lembert stitches, the passage of the ligature through the adjacent viscera, the tying of a knot, a few more Lembert stitches, and the operation on the intestine is completed. There is no incision of the bowel, no loss of blood, no escape of fæces, and no exposure to peritoneal infection from the bowel contents. The operation is followed by a minimum of shock and pain and at the end of three to four days there is an anastomosis with a union by first intention." . . . "The superiority of the elastic ligature over all other methods when an enteroenterostomy is added to a gastroenterostomy cannot be doubted by any one who has used the procedure. The quickness of its application, its freedom from danger, of sepsis, and absence of all complications are in brilliant contrast to the defects of other methods."

On basis of my own, though limited, experience, I can but indorse every one of these words. I shall surely continue to use the method wherever possible.

REPORT OF A CASE OF PENETRATING WOUND OF THE ABDOMEN WITH PROTRUSION OF VISCERA AND INJURY TO THE STOMACH—OPERATION—WITH A LATER DEVELOPMENT OF RENAL SYMPTOMS—RECOVERY.

By WILLIAM V PASCUAL M D
BROOKLYN, N Y
LATE HOUSE SURGEON TO ST MARY'S HOSPITAL

Howard Mac F——, aged twelve years, was admitted to St Mary's Hospital at 5 P M., September 23, 1901.

Previous History—Had scarlatina several years ago, without renal complications or sequelæ.

Present History.—While bathing in a shallow pond, about forty-five minutes before admission, the patient threw himself, face foremost, into the water. His left umbilical region, striking forcibly upon a jagged, rusty piece of old iron, produced a penetrating wound of the abdominal wall, through which the viscera protruded. He was brought in by the ambulance.

Examination on Admission.—The patient was in a state of moderate shock, semi-conscious, with skin pallid and cold, pulse rapid, but regular, and of fairly good quality. There was a penetrating wound of the abdominal wall on the left side, beginning at a point midway between the ensiform cartilage and the umbilicus, and at the middle of the rectus muscle, extending thence downward and outward for a distance of six inches. The wound involved the entire thickness of the abdominal wall, the rectus being severed transversely through its outer half and the oblique muscles the full length of the skin wound. Protruding through this opening were almost the entire stomach, the transverse colon, all of the greater omentum, and about three feet of the small intestine. The only injury to these organs was a laceration completely through the peritoneum of the anterior wall of stomach, the muscular layer being bruised but not perforated. This laceration of peritoneum was linear, one and one-half inches in length, and at right angle to the central point of the greater curvature.

Operation—The patient was taken to the operating room immediately and etherized. The exposed parts were protected with hot towels, while the skin about the wound was rendered as clean as possible. After the exposed viscera had been thoroughly washed with hot decinormal salt solution, the wound of the stomach was closed with a continuous Lembert suture of fine silk. After careful examination for further injuries, the viscera were returned to the abdominal cavity, and a careful search was made to determine any other internal injury. The abdomen was then thoroughly flushed with the saline solution (about 10½ gallons being used), and the abdominal wound was closed without drainage. The peritoneum and muscular layers were sewed separately with catgut and chromicized catgut respectively—the severed rectus muscle also being united—the fascia was sewed with continuous catgut sutures and the skin with interrupted silkworm-gut sutures. A few strands of silkworm gut were inserted under the skin at the lower end of the wound, for purpose of drainage in case suppuration should develop in the abdominal wall. I might add that the wound had been slightly enlarged at its upper end to allow more room for examination of the viscera.

The boy reacted well after the operation and made an uneventful recovery from the injury and operation. No untoward symptoms developed; the bowels moved within twenty-four hours after operation; the temperature, which was 100° after operation, gradually returned to normal, the pulse was good throughout, and stimulation was entirely cut off after thirty-six hours. The wound healed by primary union. The patient first took nourishment by mouth forty-eight hours after the operation; this consisted of broth and liquid peptonoids. Fluid diet was continued and gradually increased in quantity and variety until the twelfth day after operation, when a semi-solid diet of milk toast and custard was allowed.

On October 5, thirteen days after the operation, the patient became quite restless and vomited twice. Up to this time he had been doing very well; in fact, his general condition was excellent, the wound was entirely healed, and the urine was normal. On October 6, he was somewhat languid and vomited four times a greenish watery fluid; the bowels moved slightly. October 7 the condition was about the same; he vomited three times; nothing was given by mouth, nourishment being given per rectum. There were marked pain and tenderness over the right side of the abdomen—at first markedly over the appendix—later, more marked higher up. At this stage, a consultation resulted in a provisional diagnosis of a partial intestinal obstruction high up—there was no tympanites, no perceptible tumor, no rise of temperature, no change in the character of the pulse. October 8, during the night, the bowels moved twice, but only one ounce of urine was voided; this, for the first time, showed presence of albumin and hyaline casts. During the morning the boy became blind and had three slight uræmic convulsions involving the facial and cervical muscles. A condition of acute uræmia being evident, treatment by hot packs, rectal irrigations, nitroglycerin (contraction of the arteries being present), and small doses of bromide of potassium and chloral was instistuted, and with prompt and effectual response. The boy had five more convulsions on the same day, but after treatment began to have effect, they ceased. October 9, there was slight improvement, the pulse was more rapid, 100, but of better quality; the temperature rose to 101$\frac{3}{5}$° from normal; the mental condition was better, there being only stupor—no convulsions; the urine was entirely suppressed, the bowels moving freely. During the succeeding days the patient improved gradually, especially as to mental condition; he became less stupid, vision returned, vomiting ceased, the bowels moved, but the urine was suppressed totally, and subcutaneous œdema developed. This condition continued for five days (120 hours since the last urination), during which time the temperature ranged between 102° and 99°, and the pulse between 90 and 100, while there was marked and steady improvement in all the other symptoms. During this time the bladder was always empty, but the patient voided a thin bloody fluid in quantities of ʒ ss. to ʒ j.—in all ʒ vss. being voided in five days. The patient was getting diuretics, such as acetate of potassium and infusion of digitalis, and had had counter-irritation applied over the kidneys. On October 12, after a total suppression of urine had existed for five days, the boy began to urinate and during the next ten hours passed 114 ounces, the following 12 hours 87 ounces of urine. The first was somewhat bloody, later it became clear; the specific gravity was 1,010; there was a marked trace of albumin, and the urine contained many red and white blood cells and granular casts. The urine gradually diminished in quantity until it became normal and its abnormal constituents diminished. Œdema disappeared, vision was normal, and the patient became bright and cheerful. When he was discharged, October 24, there was still a trace of albumin in the urine and a few finely granular casts; the sp. gr. was 1,010.

At the present writing, the patient is up and about and is gradually regaining strength, but the urine still shows a faint trace of albumin and some casts.

A Case of Nutmeg Poisoning.—E. E. Hinman reports the case of a woman of thirty-six years who was in the habit of eating nutmegs, of which she was very fond. On one occasion she ate four or five whole nutmegs. In a few hours she began to feel queerly, weak, dizzy, and hardly able to walk. When seen several hours later, she was in a condition of collapse. She was extremely pallid, the pulse was 150, feeble and irregular; the pupils were about three-quarters dilated, and refusing to respond to light or accommodation; respirations about 23, and shallow. She complained of an intense dryness of the mouth and throat, a feeling of constriction, amounting almost to pain, across the frontal region, vertigo on the least exertion, and numbness of the legs and hands. All objects appeared to be very distant, and as she looked at those near by, they quickly receded. Objects in the left half of the field of vision appeared to be a chocolate-brown color, while those on the opposite side were normal in color. Sounds also were all apparently distant. She was too weak to turn in bed, and when she was raised, everything became black before her eyes. The most peculiar symptom present was a tendency to pass into a dreamy sleep with the eyes wide open. Even while talking, she would suddenly stop speaking for a moment or two and lie perfectly still, looking directly at me, winking occasionally, and then resume her conversation, remarking that she had been asleep, and been dreaming of doing various things. Treatment consisted in clearing out the intestinal tract and of mild stimulation. Under these measures, recovery was prompt and without incident.—*Albany Medical Annals.*

Administration of Quinine by Hypodermoclysis.—J. W. Gray, Jr., says that the principal objections to giving quinine by intravenous injection are the difficulty of the technique and the danger of paralysis of the heart, if the solution be thrown too rapidly into the circulation. However, if slowly and carefully done, it is safe and very effective. He advises the method of hypodermoclysis, or the administration of a weak, hot solution, one-fourth to one-half of 1 per cent. of quinine in deci-normal salt solution, by hypodermoclysis. The most dangerous manifestations in all malarial paroxysms are characterized by the stasis of the circulation and imperfect elimination of toxins and waste products, and the author says that he knows of no better method of combating that tendency than the ingestion of a large quantity of deci-normal salt solution. The addition of the small percentage of quinine in nowise detracts from its value, nor does it add to the irritation, so that we are able to meet two therapeutic indications at once. The solution that he prefers is 30 gr. of bimuriate of quinine and iron in a pint of deci-normal salt solution. He uses a medium-sized aspirating needle. The solution may be injected, with due aseptic precautions, into the loose subcutaneous tissue in any part of the body, or in urgent cases it may be thrown directly into a vein. The injection is not very painful, the absorption is rapid, cinchonism is prompt, and induration or local necrosis has never been produced.—*Memphis Medical Monthly.*

The Antiseptic and Eliminative Treatment of Typhoid Fever.—J. Virgil Hubbard begins by giving the patient a capsule of calomel ½ grain, guaiacol carbonate 2 grains, podophyllin $\frac{1}{40}$ grain, every two hours for twenty-four to forty-eight hours, depending upon the condition of the bowels. When there have been four or five evacuations for two successive days, ½ grain menthol is substituted for the calomel. Should inactivity of the bowels follow, a dose of salts or Hunyádi water may be given in the morning. Two or more evacuations should be secured daily, depending upon the temperature and the condition of the bowels. If after three or four days of treatment the temperature remains high, or rises after having remained stationary, the author again resorts to calomel for twenty-four hours or less, as necessary, and it invariably reduces the temperature and results in general improvement. Guaiacol and menthol are given throughout the disease. Guaiacol carbonate, aside from its antiseptic effect in preventing intestinal putrefaction, seems to have some favorable influence over the disease. The author has treated thirty-five cases in this way without a death, and in every case the temperature reached normal by the morning of the fourteenth day without the use of antipyretics.—*Georgia Journal of Medicine and Surgery.*

Climate for Consumptives.—Chauvain says that the afebrile consumptive should seek a high altitude, while the feverish patient should seek the seashore.

Types of the two climates are Davos in the Alps and the Riviera on the Mediterranean. In the mountains the season is the entire year, save when the snow is melting. At the seashore (in warm countries) from October to May.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, January 25, 1902.

BOVINE AND HUMAN TUBERCULOSIS.

CERTAINLY the most interesting, and at least one of the most important, phases of the tuberculosis question is the relation of bovine tuberculosis to the public health. Is it indeed a fact that the disease as it affects cattle differs materially from human tuberculosis and that man is insusceptible to bovine tuberculosis?

Many have thought for a long time, and still think, that the menace of tuberculous meat and of milk infected with tubercle bacilli has been much exaggerated. Among this number are Dr. Theobald Smith and Professor Adami, but that it is impossible to communicate the germs of the malady from beast to man has not as yet been proved or generally credited.

Evidence up to the present time rather points to the opposite conclusion. Consequently Koch's thesis is generally looked upon as premature, and founded upon experiments which were by no means convincing.

Since the British Congress on Tuberculosis, there has been a remarkable recrudescence of activity in this line of research, and eminent scientific men on this and the European Continent have set themselves the task of finally solving the problem.

Dr. Ravenal, Professors Bang, Nocard, G. Sims, Woodhead, McFaydean, Delepine, Dr. George Still, Lord Lister, and others have delivered weighty pronouncements against accepting the theory without reserve, while some of these scientists have conducted investigations which would appear to demonstrate that, under certain conditions, bovine tuberculosis may be transmitted to the human kind.

Dr. D. E. Salmon, Chief of Bureau of Animal Industry, U. S. Department of Agriculture, read a paper on the subject before the American Public Health Association in Buffalo in September last, in which the essential points are clearly presented, and the evidence collected is opposed to Koch's statements at the British Congress on Tuberculosis.

The report of the Committee of the American Public Health Association, of which Dr. Salmon was Chairman and from which he cites numerous facts bearing on the matter, provides powerful arguments in support of the possibility of man becoming infected with the germs of consumption by the agency of the bovine race.

So much solid matter and statistics in connection with the points at issue have been collected in this report that it will not be within the scope of an article to do more than touch upon its more salient features.

Reference is made to the experiments of Chauveau showing that human tuberculosis can be communicated to cattle, and attention is drawn to the fact that tuberculin made from human bacilli causes a reaction in cattle affected with bovine tuberculosis, a sufficient evidence that the germs from human sources are not specifically distinct.

The report treats of accidental inoculations of man with bovine bacilli, bringing forward numerous illustrations in support of such occurrences.

However, the most engrossing part of the report is that which deals with statistics showing frequency of abdominal tuberculosis.

There is much apparent discrepancy between statistics of this kind collected in Great Britain and in other countries of the civilized world. The late Dr. Thorne in 1898 proved statistically that while consumption on the whole had declined to a wonderful extent, both as regards mortality and incidence since 1851, that "tabes mesenterica" had decreased but slightly. The observations of many other medical men in Great Britain confirm these statistics.

In Germany, France, and America results differ widely. Koch says that among many cases of tuberculosis examined after death he remembered having seen primary tuberculosis of the intestines only twice. Baginsky never found tuberculosis of the intestines without simultaneous disease of the lungs and bronchial glands.

The statistics of Berlin, Paris, New York, Boston and Chicago show that, although pulmonary tuberculosis is very prevalent, the cases of disease affecting the intestines are extremely rare.

Why, then, is tabes mesenterica so common in Great Britain? Dr. Salmon is of the opinion that on the European Continent there is a stricter inspection of meat and milk, and that in the United States we have far less tuberculosis among cattle and also an efficient Federal meat inspection.

The MEDICAL RECORD has insisted both before and after Koch's speech in London that the most rigid precautions possible should be taken to protect meat and milk from contamination.

Even if the distinguished German be proved right in his views, it will still be to the best interests of the general public that meat and milk should be free from infection.

Dr. Salmon is quite as insistent on these points, and also thinks with the MEDICAL RECORD that the dramatic promulgation of Koch's doctrine will in the long run bring good to the cause of sanitation.

In the meanwhile, boards of health will do well to act as if tuberculous meat and milk were in truth as dangerous to health as formerly thought to be. Over-carefulness in like instances is not a fault, but a virtue.

SMALLPOX AND ITS PREVENTION.

SMALLPOX, on both sides of the Atlantic, has been exciting much attention recently by reason of its spread, and also on account of the seeming comparative ineffectiveness of preventive measures. There would appear to be but little doubt that this inability to cope successfully with the disease, and to sweep it away, is due to several causes, the most prominent of which are the lack of efficient vaccination, the need of more stringent means for checking its dissemination, and in a lesser degree the difficulties in the way of correctly diagnosing the malady in its primary stages.

The conditions prevailing in this country with regard to these three causes do not altogether resemble those of Great Britain; nevertheless, there is sufficient similarity between them to make any authoritative statements on the subject advanced in one land instructive in the other land.

In the *English Public Health Journal* of January, a symposium of London public health officers is presented. The first paper is by Dr. John F. J. Sikes, medical officer of health for the large and important district of St. Pancras, in which smallpox has been particularly rife for a considerable time.

Dr. Sikes reaches the following conclusions: (1) That smallpox is an imported disease, imported (*a*) from abroad, and (*b*) from town to town; (2) That smallpox is imported and spread from person to person (*a*) by unrecognized cases, (*b*) by cases delayed in recognition, and (*c*) by incubating cases probably between falling ill and development of the rash; (3) That smallpox is carried by the dirty linen and clothing (*a*) of unrecognized cases, and (*b*) occasionally of recognized cases; (4) That smallpox is also carried by persons brought into contact with infected cases, probably by the clothing, and that these contacts may also incubate, develop, and spread the disease and so reiterate the cycle.

The St. Pancras medical officer thinks that with a view to prevention, the first point for consideration is the international notification of smallpox, and points in support of his opinions to the difficulty, indeed, under the existing regulations in Great Britain, to the impossibility of preventing the importation of the disease from foreign countries, or from different parts of the country itself. Dr. Sikes holds that if international notification of smallpox should be instituted, there would be a greater opportunity for stamping out the disease than with any other infectious ailment.

The second point for consideration is extension of the instructions to be given to vaccination officials as to suspicious rashes and ailments, and observed by them in course of their duties. The writer well says that early discovery of cases is of the greatest importance. Persons having the disease mildly are extremely dangerous in spreading it widely. Individuals when smallpox is prevalent, who are suffering from an eruptive skin affection, of whose nature they are ignorant, should, without delay, consult a medical man; many, however, will not do this, so that in the interests of the public at large, wider powers might with advantage be given to vaccination officials.

Another point that Dr. Sikes believes should be insisted upon is that the law should require, in every case of vaccination, the operation should be thoroughly efficient, and that a description of the result obtained should form part of the certificate. In this manner those who seek the protection of vaccination would be reassured by more certain safety, and those who do not would realize more distinctly their danger and responsibility.

A measure which the London expert is of the opinion would be beneficial is the provision of clinical examination in doubtful cases.

In the discussion which followed the reading of Dr. Sikes the opinion of all present seemed to be unanimous in favor of a stricter quarantine of the vagrant class. It was thought that there should be power to restrict their movements when they became a source of danger, even to quarantining common lodging houses completely. Again, the members of the meeting were all agreed that in those instances in which the practitioner summoned was in the least uncertain as to diagnosis, he should, when possible, call in an expert. Attention was drawn to the fact, that there was no hardship to the ordinary consultant in doing this, for, to put it bluntly, consultants in the best practice had the least knowledge of smallpox.

The portions of Dr. Sikes' paper which will mainly interest physicians in this country, are the lack of efficient vaccination, the need of more stringent measures for preventing the spread of smallpox, and the vital importance of a correct diagnosis.

The remedies, therefore, for these deficiencies as recommended by Dr. Sikes, will, to some extent, be as applicable to cities of the United States as to those of Great Britain. Efficient vaccination is the only reliable means of prevention, and, if smallpox is to be abolished, must be strictly enforced. When, however, the disease has broken out, correct diagnosis and rigid regulations to insure the detection and isolation of those infected is necessary to check its spread.

The City of Buffalo has recognized this latter fact, its Common Council having recently decided to pay physicians to find smallpox patients who have been hidden by friends. There is no reason why, if a sound policy with regard to smallpox be carried out the disease should not be stamped out.

MEDICAL EDITORS AND "LAY PUBLISHERS."

The announcement is made by Dr. J. Duncan Emmet, the editor and proprietor, since its establishment, of the *American Gynecological and Obstetrical Journal*, that the tenth anniversary of his paper is its last, and that the right of title has been neither sold nor given away, so that any one wishing to appropriate the same when the copyright runs out is at liberty to do so. In other words, a property which, in competent hands, should have in ten years acquired considerable value is tossed aside as worthless, and the name and good will of an established journal can be had for the picking up. Thus ends one, we believe the first of this special kind, of the foolish attempts to combine business and science in the same individual, which a few would-be leaders and self-constituted mouth-pieces of the medical profession in this country have pretended to regard both feasible and desirable.

These men, with very evident ends of their own to attain, have argued plausibly enough that medical journals should be conducted in the interests of the medical profession; and did they stop here, there would be no gainsaying them. But they have gone further and hazarded the *non sequitur* that a medical journal owned by a layman must necessarily be run wholly in the interests of the publisher and against those of the readers. They, of course, knov well that the interests of editor, readers, and publisher are one and cannot be divorced without injud to all; but such an admission would be fatal to tect argument.

A moment's consideration of the causes o the failure of Dr. Emmet's journal will show tl vales- practicability of the medical-publisher ide nission paper did not go under because of the editor's intellectual weakness, for he did his work quite creditably from the start, and had it been the making of a [illegible] [illegible] with a little more experience; but as a publisher, as he himself confesses, he was a lamentable failure. He tells us in his valedictory that in the ten years of the journal's life over five thousand subscribers received and contracted to pay for the paper, but never did pay, and that "over $10,000 had been lost through unpaid subscriptions or contracts freely entered into by medical men." It is the old story of a man attempting to do what he was never fitted by education or training to undertake. As well might the so-called "lay" publisher try his hand at editing; his folly and his failure would be no less conspicuous.

There are two entirely distinct, yet not antagonistic, departments in a medical journal as in all periodicals, the professional and the commercial, or the editorial and the publishing. The business part of the journal must necessarily be conducted by a trained business man, just as the editorial part must be conducted by educated medical men who are known and trusted by their professional brethren. If the editor gives his readers a journal that meets their wants, presenting to them all that is new and good, and laying before them each week a faithful record of the progress of medical science in all its branches, his readers ought to be, and we feel sure in most cases are, content and concern themselves little where the financial profit, if profit there be, goes. Four of the seven larger weekly journals in this country are owned by laymen, but they are edited by responsible medical men whose names are published regularly, and so are known to all the readers of these journals. These editors have a reputation to preserve, and they would not dare, assuming they were capable of such perfidy, to betray the trust reposed in them by their medical brethren. They are working faithfully for the good of their profession, untrammeled by commercial restrictions, and there is not one of them who would do violence to his conscience at the bidding of his publisher were the latter so foolish as to attempt coercion. We have never heard of a serious attempt of this kind being made, and the only authentic instance of lay censorship over a medical journal that has come to our notice was, alas, that of a journal said to be owned and run by professional men and nominally edited by the most vociferous of all the decriers of so-called "lay" publishers.

It is time, indeed, to put an end to this silly and disingenuous twaddle about "lay" control of medical editors. The business man is the one to conduct the purely business matter of publication, the medical man is the one to control the purely professional matter of editorial management, and any attempt to combine or to confuse the two distinct functions is folly, and quite certain to result sooner or later in disaster, as the death of our gynecological contemporary bears witness.

Philadelphia Medical Club.—At the tenth annual meeting, held January 17, the following officers were elected for the ensuing year: *President*, Dr. E. L. Duer; *Vice-Presidents*, Drs. Thomas H. Fenton and A. McAlister; *Secretary*, Dr. Guy Hinsdale; *Treasurer*, Dr. F. Savary Pearce.

THE DIAGNOSIS OF SMALLPOX.

Much stress has recently been laid upon the necessity, in the interest of the health of all members of the community, of smallpox being diagnosed with certainty in the first instance.

Mistaken diagnoses are responsible for the spread of the disease to some extent, and it would be well that the chances of error should be minimized as far as possible. To attain this object physicians need to be able to distinguish between the eruption of early modified smallpox and chickenpox, the rashes of these maladies resembling each other somewhat closely in their prodromal stages. Dr. J. MacCombie read before the Hunterian Society in London on November 13 last a paper on the differential diagnosis of smallpox. Dr. MacCombie holds that the diagnostic points between chickenpox and smallpox are the following: (1) The distribution of the eruption, (2) The shape of the vesicles, (3) The unilocular character of the vesicles of chickenpox compared with the multilocular nature of the vesicles of smallpox.

In the MEDICAL RECORD, June 28, 1900, the differences between the rashes of the two diseases were editorially discussed at length, but a reiteration of the remarks quoted then with regard to the distribution of the eruption in smallpox and chickenpox—a feature of the greatest diagnostic value—will be perhaps instructive. In chickenpox the eruption is most abundant on the trunk, less so on the face, still less so on the forearms and legs, and least of all on the hands and feet. All cases of chickenpox present typical vesicles on the abdomen, chest, back, thigh, or arms.

There are some, however, who believe that an absolutely correct diagnosis of smallpox cannot be reached by an examination of the eruption, let the medical man be as experienced as he may.

MM. H. Roger and E. Weil, in *La Presse Médicale*, July 30, 1901, think that the only way of making a possible diagnosis of smallpox is in most cases to examine the blood. If an excess of lymphocytes, or especially of myelocytes, be found present, it is possible to exclude measles, scarlet fever, and purpura, and thus arrive at a diagnosis of smallpox.

Notwithstanding this opinion there is no doubt that, for all practical purposes, the diagnosis of a physician experienced in smallpox cases will be sufficiently convincing. At the present time the need is to procure the services of such persons.

MALARIA IN THE PHILIPPINES.

This disease is not only the most prevalent among the American troops in the Philippines, but is also the cause of most cases of permanent disablement. A white man in a tropical country who is attacked severely by malaria never wholly recovers his health, at any rate not while he remains in the torrid zone.

Lieutenant R. W. Andrews, late Assistant Surgeon Forty-sixth Infantry Volunteers, writes on the subject in the January issue of the Albany *Medical Annals*. He says that all the cases he saw were of the quotidian type, the tertian form so common in the United States occurs very seldom in the Philippines. The cachectic form developed very rapidly and soon rendered the soldier unfit for service. In the dry season the disease abates. The treatment for the quotidian form was a three-grain pill of quinine every two hours. Sometimes, however, as much as thirty or forty grains per day would be administered, often in solution, and with iron and arsenic. The treatment of the pernicious cases consisted of the hypodermic injection of quinine hydrochlorate in five-grain doses into the buttock hourly after the first paroxysm, with the idea of trying to prevent a second. The bilious remittent cases were treated with quinine in solution, with arsenic and iron, and the malaria cachexia with Warburg's tincture and iron, fifteen minims of the latter after each meal, and one or two pills of Warburg's tincture four times daily.

THE MILK SUPPLY OF NEW YORK.

The objects of the Rockefeller Institute were explained in the MEDICAL RECORD June 8, 1901.

The first investigation undertaken by the experts connected with the institute was that of the New York milk supply. An exhaustive report on the matter has recently been handed in, which clearly goes to show that such an investigation was sorely needed.

The work has been done thoroughly, and occupied seven months. The report proves that a large proportion of the milk supplied to the inhabitants of New York is unwholesome, and sometimes distinctly dangerous to health.

A very large number of outbreaks of infectious disease were traced to milk.

But the part of the report which will perhaps most surprise the citizens of New York is that which tells that almost the entire milk supply is more or less open to doubt. This state of affairs is due to careless and dirty methods of conducting cow farms, and of after-handling of the milk. The farms are kept in unsanitary conditions, the animals themselves are uncleanly, and the utensils improperly cared for. The report says that legislation may effect a certain amount of improvement but that an amelioration of the milk supply will be brought about, not by compulsion of the dealers, but by educating them up to the point of voluntarily doing better work.

The report will tend to compass reforms by arousing the people to a sense of their danger.

SANITATION OF CARS.

When the New York State Association of Railway Surgeons held their annual meeting at the New York Academy of Medicine on November 14, last, one of the chief subjects of discussion was the question of car sanitation.

Papers were read by Dr. G. P. Conn of Concord, by Dr. J. N. Hurty, by Dr. W. J. Rosenau of Washington, D. C., and Dr. William Park of New York.

Dr. Rosenau thought that one of the greatest strongholds of disease germs on railroad cars is the excessive ornamentation. There should, he says, be less of this, and the interior of the cars should be so arranged that it presents a smooth hard surface, which would greatly facilitate disinfection.

Dr. Park is of the opinion that we cannot rid ourselves of all danger of the spread of disease, in railroad and street cars, under present methods of fumigation. A thorough cleaning of such vehicles every day, a blowing out of the dust with compressed air, and the use of some disinfectant would make cars reasonably safe.

Dr. Hurty believes that consumptives should be prohibited from traveling in railroad cars. When they travel in railroad cars they spread contagion everywhere. If they are allowed to travel they should have separate compartments. Typhoid-fever convalescents and all other persons suffering from infectious diseases should be prohibited from traveling in public conveyances.

The hygiene of railroad and street cars has occupied the attention of physicians and sanitarians for many years; but there is yet room for much improvement, especially on some of the most important railroads and in the street cars of many of the largest and richest cities. Ventilation is ofttimes very defective in railway cars, and the street cars are as a rule inadequately heated, as well as badly ventilated.

With respect to excluding persons convalescing from infectious diseases from public conveyances, no one will deny that such a course is actuated by common sense.

It would, however, be a difficult matter to prohibit consumptives, as a body, from travelling in ordinary cars. Those in an advanced stage could of course be prevented, but those on whom the disease had not obtained a firm hold could not easily be excluded.

Car sanitation is a matter requiring drastic reforms.

ADOPTION OF UNITED STATES ARMY MEDICAL METHODS BY FOREIGN NATIONS.

The meeting of the troops of the various countries in China afforded the opportunity of comparison in all branches of the service. It was the first occasion on which our army medical department was subjected to a prolonged criticism by foreign experts, and it may be said without exaggeration that it came out of the test with flying colors. The army medical officers of other nations expressed surprise and warmest admiration at the high state of excellence reached, as regards organization and equipment by the United States Army Medical Department.

The ambulances and tents met with especial approval, so much so in fact that Canada has adopted the ambulance and Munson hospital tent. Great Britain, France, Spain, Mexico, and Chili have ordered specimens of the ambulance, while Great Britain has also procured complete sample sets of our medical, surgical, sterilizing, and detached service chests, folding field-service furniture, bathtubs, and brigade hospital mess chests.

In the MEDICAL RECORD, August 17, in some notes on the Pan-American Exposition, was given a brief sketch of a United States brigade field hospital, and the *Lancet* a few weeks later contained a description of the Munson hospital tent, the ambulance, and other details of equipment.

The United States Army Department has made for itself an enviable record.

INFECTIVITY OF PLAGUE.

The report of the Indian Plague Commission has been recently published. With regard to the question of direct infection the commissioners say that the danger of direct infection from plague patients is very small, under conditions such as those of hospitals in India, where attention is paid to the proper ventilation and cleanliness of the buildings, where the floors are, in a considerable number of the hospitals, periodically treated with disinfectants, and where precautions, such as the wearing of shoes, are as far as possible insisted on. It must further be noted that in the hospitals under consideration personal disinfection was entirely neglected by the large majority of the staff and that the relatives of the sick rarely took even the most elementary precautions against infection. These facts would seem to show that little risk is incurred by direct contact with plague patients.

Pneumonic plague, however, was found by the commissioners to be infective in a high degree.

With respect to the infectivity of patients convalescing from the plague, the president of the commission gives it as his opinion that a convalescent may cause infection for from four to six weeks after all acute symptoms have disappeared.

It is curious that little more is known concerning the means of transmission of the plague than a century ago.

OSTEOPATHY IN NEW YORK STATE.

A bill is now before the State Legislature to grant to osteopaths the same rights as those enjoyed by regularly graduated and licensed physicians. The New York *Evening Post*, January 18, aptly quotes Dr. George Helmer as to the teaching and requirements of so-called osteopathic colleges.

That gentleman boldly states that everything is taught in osteopathic colleges that all medical colleges teach, except Materia Medica. In place of that osteopathic therapeutics are substituted. There are classes in anatomy, physiology, chemistry, pathology, neurology, surgery, and in fact whatever will instruct a student in the nature of a man's body. Nothing is taught concerning drugs or medicines, except the use of antidotes and anæsthetics.

The following is the course of study, with the number of hours devoted to each subject: First term—Descriptive anatomy, five hours per week; general chemistry, five hours per week; histology, lectures, and laboratory work, three hours per week.

Second term—Descriptive anatomy, five hours per week; physiology, five hours per week; principles of osteopathy, five hours per week; physiological chemistry, urinalysis and toxicology, five hours per week; hygiene, ten lectures per term.

Third term—Regional anatomy with demonstrations on the cadaver, five hours per week; physiology, five hours per week; pathology, two hours per week; theory and practice of osteopathy, ten hours per week; clinical demonstrations, four hours per week.

Fourth term—Neurology, one hour per week; surgery, four hours per week; pathology and bacteriology in laboratory, two hours per week; gynecology, ten weeks, five hours per week; obstetrics the same; clinical demonstrations, five hours per week; clinical practice, four afternoons; medical jurisprudence, ten lectures per term; physical diagnosis, one hour per week.

It goes without saying that a man who has undergone such a course of training as a qualified osteopath, say from Kirksville, Mo., is but poorly equipped with the medical and surgical knowledge requisite to care for the bodily health and treat the injuries of his fellow-men. We commend a perusal of the osteopathic curriculum to the intelligent and sober inhabitants of this country.

THE ESSENTIALS OF SANATORIUM TREATMENT.

In view of the probable wide extension of these institutions throughout America, it will be of interest to physicians and others concerned in the matter to hear the opinions of medical men who have a good knowledge of sanatoriums for tuberculosis as to the best methods of treating those suffering from the disease. Germany was the pioneer in founding sanatoriums, and contains more of such establishments than any other country. Perhaps, however, the most convincing paper read on sanatorium treatment at the British Congress on Tuberculosis was not by a German but by a Scotchman.

Dr. R. W. Philip, physician to the Victoria Hospital for Consumption, Edinburgh, gave in the said paper the following useful hints.

Speaking of open air, he said: "Whatever may be stated to the contrary, or by way of qualification, hyperaeration is the basic and essential agent in the treatment, the sine qua non. There may be differences as to diet, rest, and exercise, but the uninterrupted exposure of the patient to the influence of fresh air is applicable in every case. In early days there was some timidity about this. Efforts were made to attain a fairly constant temperature in dwelling and bedrooms, and it was an instruction to nurses that the temperature should be regulated by the thermometer placed in each room. All this, however, has been greatly modified by experience. The freest access of fresh air is to be allowed to the patient day and night at all seasons, provided he is sufficiently clad; also rest and release from disturbing influences.

"For almost all patients rest is the immediate indication when treatment is commenced, and must be retained as part treatment at least for a long time. The pulse and temperature are the chief guides."

With improvement, Dr. Philip recommends exercise, here again its amount being gauged by careful record of pulse and temperature. The alimentary disturbances which form so marked a feature of the disease must be corrected by a carefully studied dietary. The patient must be induced to take a sufficient quantity, a very different thing from the "forced feeding" of which one sometimes hears.

Dr. Philip advises close attention to skin hygiene.

The whole paper is an excellent exposition of intelligent sanatorium treatment for consumptives as distinguished from the somewhat faddist principles which prevail in some establishments.

A LAWYER'S TRUST.

In New Jersey a corporation to be known as the "Associated Attorneys" has been formed and has obtained a charter. The incorporators are all Jersey City lawyers.

The certificate of incorporation empowers the corporation to practise law through attorneys and counselors-at-law in any part of the United States.

It is understood that the "Associated Attorneys" will advertise for business, and will make a specialty of doing law work for business houses and corporations for a stated sum per year.

The establishment of a lawyers' trust is but another sign of the commercial spirit which would seem to be invading every branch of life.

With business trusts a medical journal has no concern, and the methods now in vogue of consolidating into immense corporations the various independent trade establishments throughout the country cannot here be criticised.

But a protest may be with justice made against the introduction of like trade principles into the learned professions.

Schemes of this nature tend not only to lower the dignity of an esteemed calling, but in addition will not conduce to the pecuniary advantage of a profession as a whole.

Medical men have bitter cause to regard the dispensary system, the excessive multiplication of benefit clubs, and like means of unfairly cheapening the value of their services with deep feelings of distrust.

The action of the Jersey City lawyers is to be deprecated by members of all professions as a movement ill calculated to work for the common good.

Plague in Butter.—Plague may live a long time in butter, especially when kept cool—that is, at 17° to 19° C. The warmer the temperature, the shorter the time the organism lives. At 37° C. it remained alive but [illegible] days against [illegible]-two days at 17° to 19°C.

News of the Week.

Retirement of Surgeon-General Van Reypen, U. S. Navy.—Surgeon-General William K. Van Reypen, U. S. Navy, is to be placed on the retired list of the navy on January 25, with the retired pay of a senior rear admiral. The action was voluntary on Surgeon-General Van Reypen's part, and is in accordance with the law authorizing the retirement of an officer with advanced rank, after forty years of service, including service in the war of the rebellion. Surgeon-General Van Reypen will be succeeded by Dr. Presley M. Rixey, medical inspector, U. S. Navy, who is well known in connection with his duties as attending physician to the late President McKinley. Dr. Rixey is a native of Virginia, and entered the navy in 1874. His appointment to the position of Surgeon-General was made by President Roosevelt in conformity with a promise made to the friends of Dr. Rixey by President McKinley.

Plague in the Philippines.—In view of the existence of plague in the Philippines, General Chaffee has issued an order calling the attention of officers serving in the archipelago to the absolute necessity for the extermination of rats in barracks, quarters, and other buildings occupied by officers, enlisted men, and civilian employees, and for the immediate disinfection of such buildings if plague rats are discovered therein. The order says that in Manila the insular board of health finds that 1¾ per cent. of all rats now being collected are infected by plague, and gives an approved method for the destruction of these rodents by the use of poison. The order directs that the board of health be notified by the medical officer in charge of posts in which any infected rats are found, in order that a temporary evacuation and disinfection of the building may be effected. If possible, all buildings are to be made rat proof by the removal of old partitions and the obliteration of dead spaces between floors and walls. Official reports lately received at the War Department state that Contract Surgeon E. S. St. John, U. S. Army, who was killed by insurgents in the Philippines some months ago, lost his life while leading and in command of a detachment of infantry. In warfare such as has been going on in the Philippines, in which the neutrality of surgeons and hospital corps men is not respected, these frequently have had to become combatants during action, and could only resume their humanitarian duties at the conclusion of the action. During the active operations consequent upon the former organized resistance by the insurgents, hospital-corps men were armed with carbines while in the field, and at the present time are usually provided with revolvers under such circumstances.

Dental Surgeons for the Navy.—The benefit to the military service attending the appointment of dental surgeons in the army, as a result of the experience of the past year, has prompted the following bill to establish a similar corps of dental surgeons in the navy which has recently been introduced into Congress.

Sec. 2519. A bill to add dental surgeons to the medical corps of the navy. Be it enacted, etc., that to the medical corps of the navy there shall be attached a corps of dental surgeons to serve the officers, enlisted men, and boys in the naval military service and training schools, which corps shall not exceed in number the proportion of one to one thousand authorized by law for said service and schools.

The said dental corps shall consist of three grades designated assistant dental surgeon, passed assistant dental surgeon, and dental surgeon, and with respect to rank, pay, and allowances, and to promotion within said dental corps, the grades named shall correspond to the grades of the medical corps designated assistant surgeon, passed assistant surgeon, and surgeon, respectively.

Sec. 2. That original appointments shall be made to the grade of assistant dental surgeon, and the appointees must be citizens of the United States, between twenty-three and thirty-three years of age, graduates of standard dental colleges, with not less than two years' subsequent experience in practice, of good moral character, of unquestionable professional repute, and shall be required to pass a satisfactory physical and professional examination: Provided, that there shall first be selected a member of the dental profession who is a graduate of a standard dental college and whose aptitude and experience evidence fitness for conducting the professional examinations herein provided for, and for otherwise assisting in organizing, equipping, and supervising the operations of the corps, who shall be first appointed to the grade of dental surgeon.

Damages for the St. Louis Tetanus Cases.—A resident of St. Louis has brought suit against the city for $20,000 damages for the death of his daughter, aged four, who, he alleges, was killed by the administration of antitoxin furnished by the City Health Department. This is the first of a series of damage suits growing out of the death from tetanus of thirteen children, to whom diphtheria antitoxin, said to have been contaminated with tetanus virus, was administered.

The Medical Society of the State of New York.—The ninety-sixth annual meeting of this society will be held in the City Hall, Albany, on January 28, 29, and 30, 1902, under the presidency of Dr. Henry L. Elsner of Syracuse. Members of the county medical societies and the medical profession of the State generally are invited to attend the meeting. A full program has been published, and communications relating to any changes in the same should be sent to one of the business committee, Drs. Nathan Jacobson of Syracuse, George R. Fowler of Brooklyn, and William C. Krauss of Buffalo. The secretary of the society is Dr. Frederic C. Curtis of Albany. The reception and annual dinner will take place on Wednesday evening. Reduction in railroad fare can be secured by obtaining at the station, on starting, a certificate which, when endorsed at the meeting by the Secretary and the Special Agent of the Trunk Line Association (who will be present the first two days), will entitle to return at one-third fare. Members, both delegate and permanent, are requested to register early, to which end the committee on credentials will be at the Hotel Ten Eyck, Monday evening. Others are asked to register likewise, and to become members by invitation.

The Late Dr. George Bayles.—The following minute was adopted at a meeting of the medical staff of the Orange Memorial Hospital held January 6, 1902: "Dr. George Bayles died on December 20, 1901. He was born in New York in 1836, and received his medical degree from the College of Physicians and Surgeons, New York, in 1859. He served his country as a surgeon both during the War of the Rebellion and the Spanish War. He settled in Orange in 1880, and was appointed attending physician to the Orange Memorial Hospital in 1888. The doctor's interest in the work of the hospital was shown by informally accepting the position of anæsthetizer, and for several years he was uniformly present at every operation in the hospital. In this work he took great interest and adopted the latest methods in his practice, supplying the apparatus and gas at his own expense. His colleagues on the staff appreciate his faithfulness to them and in every relation which he bore to the hospital. His uniform courtesy and kindliness, his attention to the work of the wards, made him an agreeable associate and a useful member of the staff.

We have directed this minute to be spread upon the records of staff, and to be sent to Mrs. Bayles as an expression of our sympathy in her great loss and as an evidence of our regard and respect for the doctor.

THOS. W. HARVEY,
Secretary."

Coroners' Physicians.—The State Civil Service Commission has been asked to decide whether or not the coroners' physicians shall hold their places at the pleasure of the coroners. The President of the Board of Coroners asked the Corporation Counsel two weeks ago for an opinion as to the status of all the men under the coroners in Manhattan. Mr. Rives replied that the coroners' physicians rightly belong in civil service schedule A, which means that they can be removed at any time, and not in schedule E, men in which hold their places as long as their work is satisfactory. On the strength of this decision the coroners asked the Municipal Civil Service Board to recommend the change, and the board did. It was also approved by Mayor Low. The coroners argue that they should be able to remove their physicians at any time and put in men in whom they can have confidence, but the physicians naturally are opposed to any change. The salary of a coroners' physician is $3,000 per year.

A Physician Fined for Not Reporting a Case of Smallpox.—A Brooklyn physician pleaded guilty, one day last week, in the Court of Special Sessions to a charge of having failed to report a case of smallpox which he had attended, and was fined $50. He first diagnosed the case as one of diphtheria, but when convinced that it was smallpox had neglected to notify the health authorities.

Trouble in a Buffalo Hospital.—One of the attending physicians of the Sisters' Hospital in Buffalo is reported to have resigned recently because the resident physicians refused to give one of his patients antitoxin on the ground that the medicine was too expensive to be given away, in view of the low state of the hospital's finances. The resignation has caused much feeling among the hospital physicians, who have taken sides, three of them indorsing the resigning man's stand, while the rest take the view that he acted too hastily. He was asked to reconsider his resignation, but refused to do so.

Site for a New Maternity Hospital.—The directors of the Manhattan Maternity Hospital and Dispensary have selected a plot of four lots on East Sixtieth street, between First and Second avenues, as a site for the Maternity Hospital which is to be built by a wealthy philanthropist as a gift to the East Side poor. The name of the donor is not mentioned, but it is believed that he is included in the list of directors. The institution was incorporated last spring with Daniel S. Lamont, Cornelius Vanderbilt, Frank L. Polk, Henry S. Thompson, William Thorne, Moses Taylor and Percy R. Pyne as directors. It is the intention to provide a hospital, a dispensary, and a training school for nurses, housed in a building equipped with every modern appliance. There will also be an outdoor service of obstetricians and nurses. The service will, in general, be free, but there will be a few rooms for pay patients.

Transfers of Patients to City Hospitals.—It has long been alleged that the private hospitals in this city have made a practice of transferring patients who were penniless and likely to die to Bellevue, which institution has also been accused of railroading dying patients to the hospitals on the islands. In the apparent belief that this abuse does exist, and in the hope of stopping it, Mr. Homer Folks, the new Commissioner of Charities, has issued the following order: "No patient in any hospital in this department whose condition is such as to lead the attending physician or the examining physician to believe that a fatal result must be expected within three days shall be discharged or transferred to any other hospital unless such patient is violent and there are no facilities for safe restraint in the hospital in which he may be. In case any patient received by any hospital in this department by transfer from some other hospital or institution within or without this department, shall die within three days after admission, a statement of the case shall be reported immediately to the commissioner."

The State Sanatorium for Consumptives.—At a meeting of the Board of Trustees of the State Hospital for the care of persons suffering from incipient tuberculosis, held this week in Albany, plans for the hospital buildings to be erected on the site at Raybrook, between Lakes Placid and Saranac, in the Adirondack region, were submitted. It is expected that work on the construction of the buildings will be begun as soon as possible, and that they will be ready for occupancy next autumn. There is an appropriation of $150,000 available to defray the cost of the buildings. After the sanatorium is open, an annual appropriation by the Legislature will be required for its maintenance.

Measles in Flushing.—Within a week 400 cases of measles have been reported to the office of the Board of Health from Flushing. It is said that in some streets there are rows of houses every one of which has one or more cases in it. The outbreak began about ten days ago and gradually increased each day since up to the beginning of this week. In some of the schools there are rooms which contain only a skeleton of a class. The cases are said to be generally of a mild type, and no deaths have as yet resulted. The Health Board officials are doing everything in their power to check the disease.

Payment for Expert Work Enforced.—Dr. Rudolph A. Witthaus has recently won a suit against the city for $6,630.65, which he claimed was due him for making a chemical analysis of the stomach of H. Barnett, whose death was one of the significant features of the people's evidence in the Molineux murder trial. Dr. Witthaus contended that he performed the analysis at the instigation of ex-District Attorney Gardiner, and that he had put in 366 hours' work in making the analysis. His charge was $15 an hour, with $250 for consultations and $500 for incidentals. Comptroller Coler had refused to pay the bill when it was presented, contending that it was exorbitant. The verdict rendered included $450 for interest on the amount sued for.

New York City Hospital Trustees.—Mayor Low received, a short time ago, nominations for the board of trustees of Bellevue, Fordham, Harlem, Gouverneur and the Emergency hospitals. Fourteen names were presented by the presidents of the United Hebrew Charities, the St. Vincent de Paul Society, and the New York Association for Improving the Poor, and from this list the following were appointed: Howard Townsend, for the term of one year; Theodore E. Tack, two years; Marcus Stine, three years; James K. Paulding, four years; Samuel Sachs, five years; Myles Tierney, six years; Dr. John W. Brannan, seven years. After having been sworn in and instructed in their duties by the Mayor the trustees organized by electing Dr. Brannan, *President*, and Mr. Paulding, *Secretary*.

The Canton (Ohio) Medical Society.—The annual meeting, election of officers, and banquet of this society took place Friday evening, January 3, 1902. The address of the evening was delivered by the retiring president, Dr. E. O. Morrow, on "Treatment of Ninety-seven Cases of Typhoid Fever, with Two Deaths." Reports of cases were read by Drs. J. P. DeWitt, F. W. Gavin, and F. Da Hinden. The following officers were elected for 1902: *President,* Dr. John P. DeWitt; *Vice-President,* Dr. Robt. B. Williams; *Recording Secretary,* Dr. Wallace Foulks; *Corresponding Secretary,* Dr. Frank Kahler; *Treasurer,* Dr. Frank Da Hinden; *Board of Censors,* Drs. Harry M. Schiffell, A. B. Walker, and Edward P. Morrow.

Obituary Notes.—Dr. William Merwin Smith, who was for many years Health Officer of the Port of New York, died, on January 17, in Redlands, Cal., at the age of seventy-five years. He was formerly Surgeon-General on Governor Dix's Staff, and was Surgeon of the Third Brigade in the Civil War. He resided in Brooklyn for a number of years after retiring from Quarantine.

Dr. J. T. Eskridge of Denver died at his home in that city of Bright's disease on January 16. He was born in Sussex County, Delaware, and was a graduate of the Jefferson Medical College in 1875. For a time he was post-graduate instructor in nervous diseases in that college, but removed to Denver in 1884. He was a member of many national and local medical societies, and was a recognized authority in nervous and especially mental diseases.

Dr. Clayton Parkhill of Denver died there of Bright's disease on January 16. He was a graduate of Jefferson Medical College in 1883. His illness dated from the Spanish War, during which he served as surgeon in the army, when he was greatly prostrated by tropical diarrhœa in Porto Rico. He was Professor of Surgery at the Gross Medical College in Denver, and was a prominent member of many local, State, and national medical societies.

Rev. Dr. Richard R. Horton, for thirty-five years Chaplain of the Colored Home and Hospital in this city, died last week at the age of eighty-nine years. The cause of his death was pneumonia.

Dr. Kingston Goddard died at Philadelphia on January 17 at the age of sixty-three years. He was graduated from the medical department of the University of Pennsylvania in 1859, and shortly afterward entered the United States Army as a contract surgeon. An attack of typhoid fever interrupted his career at this stage, but after his recovery he entered the navy and served as a surgeon until the close of the Civil War. He then practised medicine for several years in Cincinnati, subsequently going to Philadelphia, where he was elected coroner in 1874. He also served as school director for several years.

Dr. Samuel Seabury Jones of this city died at his home, 712 Madison Avenue, on January 21, of pneumonia. He was born in Oyster Bay, L. I., fifty-five years ago, and was graduated from the arts and medical departments of the New York University, being admitted to practice in 1869. He was a member of the Academy of Medicine, the Medical Society of the County of New York, the Manhattan Medical and Surgical Society, and the Lenox Medical Society, and was also consulting physician at the Almshouse and Workhouse Hospitals. He leaves a wife and two daughters.

Dr. Thomas Johnson died at his home in Readington, N. J., on January 19, at the age of eighty-seven years. He was born in Somerville, N. J., and studied medicine in the office of his father, Dr. William Johnson of that town. After practising in Somerville for a number of years, he removed to Readington about forty years ago, and actively followed his profession there up to within a few years of his death. A widow and one daughter survive him.

Obituary.

GEH. MEDIZINALRAT HUGO WILHELM VON ZIEMSSEN,

MUNICH.

Professor von Ziemssen died at his home in Munich on January 21, at the age of seventy-nine years. He was born in Greifswald on December 13, 1829, and after passing through the Gymnasium in his native city, studied medicine at the universities of Berlin, Würzburg, and Greifswald, from 1849 to 1853. While in Würzburg he was for a year private assistant to Virchow. He received his doctorate degree at Greifswald in 1853, and passed his Staatsexamen (to obtain his license to practise medicine) *summa cum laude* at Berlin in 1854. He returned to Greifswald, where, in 1856, he was appointed assistant at the medical clinic, serving under Haeser, von Niemeyer, and Rühle, and in 1861 was promoted to be an extraordinary professor. Two years later, in 1863, he accepted the chair of Pathology and Therapeutics, with the directorship of the medical clinics, at Erlangen, remaining there until 1874, when he was called to Munich, where he was made Professor of Special Pathology and Therapeutics and Director of the City General Hospital. Here he established the first "Klinische Institut" in Germany, and remained its director until his death. During the Franco-German War he directed a hospital train, running for a time between Nuremberg and the base of operations in France, and was also at the head of a Committee of Sanitary Assistance which rendered especial services in the military hospitals at Metz.

Few medical men have had lives of greater literary activity than von Ziemssen, for his industry in this direction was extraordinary. His first publication (1854) was his Inaugural Dissertation, or graduation thesis, entitled "De Gangrænæ Nosocomialis Historia et Literatura." In 1857 he wrote a treatise on "Electricity in Medicine," and in 1866 published a monograph on "Pleurisy and Pneumonia in Childhood." In 1862 he founded the "Greifswald Medical Reports," which he edited for two years, making himself seven important contributions to the series. In 1865 he established, in conjunction with Professor A. Zenter, the *Deutsches Archiv für klinische Medicin,* contributing to the same many papers, especially on diseases of the respiratory organs, a subject in which he was always particularly interested. In 1874 he began the publication of his world-known "Handbuch der speciellen Pathologie und Therapie," which was translated in this country under the editorship of Dr. Albert H. Buck, and published by William Wood and Company under the title of Ziemssen's "Cyclopædia of the Practice of Medicine." To this, as to all the works of which he was editor, von Ziemssen made numerous contributions with his own pen. In 1883 he began his "Handbuch der allgemeinen Therapie" in four volumes, which was later included in the "Handbuch der Hygiene und der Gewebekrankheiten." He also edited a "Handbuch der Hautkrankheiten," and a series of "Klinische Vorträge," which ran through twenty-five numbers. In addition to the articles written for his own cyclopædic works, he was a frequent contributor to periodical literature, and to various "Sammelwerke," edited by Penzoldt and Stintzing, von Leyden, and others.

German medicine, and indeed the medical literature of the entire world, owes to this indefatigable worker an enormous debt, which it should not be slow to recognize.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

THE PROGRESS OF THE EPIDEMIC — MENINGITIS SIMULATING ECLAMPSIA — CHORIO-EPITHELIOMA MALIGNUM — [illegible] "FRIVOLS." — MISCELLANEOUS NOTES.

LONDON, [illegible]

Smallpox continues to spread. During the week the number of fresh cases has increased and other localities have become infected. Those who for months refused to apply the word epidemic to the outbreak are now beginning to use it, and fears are freely expressed as to what may happen if the disease cannot be stamped out before the coronation, when great crowds will be attracted to the metropolis. Already the home counties are being invaded, and reports of cases are being brought from many of the most accessible places, most of them being, it is alleged, traced to persons arriving from London.

The epidemic is now actually assuming proportions which threaten to equal or surpass those of 1884-5, as will be seen if we look back over the past year. There were a few cases in the first quarter of 1901. In the month of May there were 6, in June, 15, in July, 28. In August came the first sudden extension, when 96 fresh cases were admitted, followed in September by 188, in October 297, in November 473, and in December, 584. The year closed with 35 cases on its last day, and the new year opened with the same number on its first day. The daily numbers then were 24, 38, 32, 39, until January 6, when they jumped to 56, and the next day 53 were added, and the next a fall to 34 was noticed. Yesterday there were 57 new notifications, and the number under treatment had passed the ninth hundred.

The difficulty of dealing with some people is illustrated by a story that a steamer in the Thames signaled "all well," and so was not inspected for some time, and meanwhile the crew had been paid off, and disappeared, although a man with smallpox was lying in the forecastle. I should hope the commander will be brought to book.

To-morrow, the Asylums Board will issue a report on the epidemic. Meantime, the antis are busy circulating their misleading leaflets and false figures.

Sir J. Crichton Browne gave an inaugural address to the Sanitary Inspectors' Association on Saturday, in which he referred specially to their duties in reference to the smallpox epidemic. If this pursues its usual course, he told them, it will reach its highest level between this month and May, and that level may mean a formidable amount of disease, for sudden extensions are not improbable. Insignificant therefore, as the present outbreak is, compared with former epidemics, he said it is calculated to cause anxiety. He quoted statistics to show that among the vaccinated the death rate was 20 per cent., while among the unvaccinated it was 60 per cent.—threefold. In every quinquennial period the fatality had been greater among the unvaccinated. The power of vaccination, however, diminished gradually from the date of operation, showing the necessity of re-vaccination. The "conscience clause," by removing every vestige of persecution, had converted the anti-vaccinationist from a martyr to a mere crank, and so far improved matters. The case of Montreal was cited to show the stupidity of opposing vaccination. That city enjoyed immunity from 1875 to 1885, a period of neglect followed, an unprotected population grew up, and when a case was introduced by a visitor, the disease spread like fire in dry grass, and killed 3,154 citizens.

The Obstetrical Society began the new year with an interesting meeting on the 1st inst., when two good papers were presented and discussed.

Dr. Thos. Wilson of Birmingham read the first of these, which was on a case of pneumococcic meningitis simulating puerperal eclampsia. The patient was comatose on admission, and died within an hour and a half. Some urine drawn off shortly before death contained a slight amount of albumin and 1.5 per cent. of sugar. The post mortem showed the kidneys, uterus, and ovum to be healthy. The chief morbid condition was septic meningitis involving the whole surface of the brain. There was œdema of the lungs, but no pleurisy, pneumonia, pericarditis, or peritonitis, no tuberculosis, no middle-ear disease. A cultivation of the pus on the meninges revealed an organism resembling Fraenkel's pneumococcus. Dr. Wilson said his case could not be distinguished from eclampsia, and urged the importance of a complete post mortem in every fatal case of convulsions or coma during pregnancy. He suggested that the origin might have been derived from reabsorption from the breasts.

Dr. A. Routh doubted this in view of recent experiments, and suggested the sugar might have been derived from the liver.

Dr. Spencer mentioned a case in which he operated for pyosalpinx, in which there was much pus, but which did well until the tenth day, when the odor of the breath led to the urine being examined for sugar, which was found. Paralytic symptoms supervened, ending in death, which was thought by Sir W. Gowers to be due to septic meningitis involving one hemisphere. The occurrence of the sugar in this case and in Dr. Wilson's suggests that it may be related to cerebral sepsis.

Dr. Cuthbert Lockyer read the other paper to which I referred above. It consisted of an account of a case of chorio-epithelioma with pulmonary metastases. The main features shown in sections of the primary growth were carefully described. No true chorionic villi were demonstrated, but syncytial masses formed the main feature of the growth and were also found in the metastases. Dr. Lockyer said two varieties of tumor termed deciduoma malignum are histologically distinct: (1) Syncytioma, derived from the outer layer of the chorionic villi. (2) Tumors containing no syncytium, made up of large multinucleated connective-tissue cells, closely resembling the decidual cells of the maternal portion of the placenta. These two varieties were shown in a lantern demonstration.

The President (Dr. Horrocks) complimented Dr. Lockyer on his paper and demonstration. He rather leaned to the opinion that these malignant growths were of fetal origin, a view supported by those cases in which he followed hydatidiform degeneration of the chorion.

Dr. H. Spencer agreed as to the two kinds of case, but thought it convenient to retain the term deciduoma malignum to include the two varieties. He mentioned that at a former discussion the late Dr. Kanthack considered these growths should be classed as sarcomata.

At the same meeting Dr. Lewers showed two specimens of cancer of the body of the uterus which he had removed by abdominal panhysterectomy. Dr. McCann raised the question whether the tubes and ovaries should not be removed in every case of cancer of the body, as he had seen recurrence in the tubes. Dr. A. Routh thought if the growth did not involve the cornua the tubes might be left, but when the whole fundus was involved, they ought to be removed.

When Sir F. Treves used the expression, "the plague of women," there was a great outcry among the nurses. His justification now comes from one of themselves, who, in the *Nursing Record*, writes about those whose pursuit of pleasure and flirtation caused their more serious sisters to nickname them "frivols." Nothing more severe has been said than this: "Gadding, junketing, riding, driving, racing, dancing, picnics, and 'high, old times' are the unblushing aim of the frivol." The war-office schemes for reforming the nursing department can hardly make bad worse, but it is high time that the medical officers were given more authority, that they might enforce discipline on the nursing women. If the soldiers and their surgeons were consulted, a great number of these women would be dismissed, and their places supplied by male nurses trained in the army hospitals.

My new Medical Directory was delivered before the close of the past year. The net increase in the number of names over the previous issue is 434. The increase is noted in all the divisions. The average on the whole is 1.19 per cent.

The late Mr. France, consulting ophthalmic surgeon to Guy's Hospital, left money to the Council of the Royal Medical Benevolent Fund to found pensions for aged necessitous members of the profession. The council has accepted the trust, and decided to found pensions of £30, calling them after the benefactor, "France pensionships."

Another society is projected—the electro-therapeutical. A meeting is to be held this evening for its formal establishment.

The Jenner Institute is making a special effort to meet the demand for reliable glycerinated vaccine lymphs.

The donor of the £200,000 which the King devotes to a sanatorium for tuberculosis is Sir Ernest Cassel, K.C.M.G., whose chief work was in connection with irrigation in Egypt.

The discussion on vaccination at the Medico-Chirurgical will be resumed on the 14th.

Charles Roberts, F.R.C.S., who died on the 8th, took great interest in statistics, meteorology, and anthropometry. Of the last subject he wrote a "Manual," and also the "Final Report" of a Committee of the British Association. He was also much interested in questions concerning the health of factory children and other hygienic subjects, on which he contributed to societies and journals. Every now and then, too, a letter of his would appear on some side subject, and whether his opinion was accepted or not, it was always worth consideration.

Dr. Hyde Hills of Cambridge died on the 2d inst. from tetanus. He was a long time on the Health Committee of the Corporation, and in 1894, Mayor.

Dr. David Ramsay of Raunds, near Northampton, has lost his life from septic infection of a wound of his finger accidentally inflicted in operating. He was graduated at Glasgow in 1888.

Dr. Tracy, physician to the Mercy Hospital, Cork, died on the 26th ult. He was treasurer of the local medical society, and enjoyed the confidence of his brethren and the public, who attended his funeral in large numbers, headed by the Lord Mayor and High Sheriff of Cork.

Dr. J. W. Mason died on the 29th ult., in his eightieth year, at Strand Green.

THE CZOLGOSZ TRIAL AND MEDICAL EXPERT TESTIMONY.

To the Editor of the Medical Record:

Sir:—The report of the trial, execution, autopsy, and mental status of Leon F. Czolgosz, published by Dr. Carlos F. MacDonald in the Medical Record of January 4 will, for obvious reasons, be widely read. As an authority upon mental and medico-legal matters, and as one of those officially appointed to examine into the sanity of the assassin, the words of the writer of the report will carry special weight. He says that the trial was "a unique one in the annals of criminal jurisprudence." Everything in regard to it deserves, therefore, more than a passing notice. The sustained dignity of the whole proceeding, the absence of all harrassing trivial technicalities of the law, the rapidity with which a satisfactory jury was obtained, and last, but not least, the avoidance of all disputation between the medical experts in open court were indeed features that added to the remarkable character of this trial, and in the end tended to make it a memorable example of what such a trial should be.

I wish to say a word here in regard to the manner of securing and presenting the expert testimony in this and other instances. That word, of course, can only be one of the highest commendation so far as the Czolgosz trial is concerned. The experts who were summoned, three by the State and two by the defense, were all men of the highest ability and known probity, men who, as intimated in the statement made by Dr. MacDonald, when referring to himself, only "consented to act, provided it should be distinctly understood" that they were not there as partisan experts "in behalf of either side, but simply in a professional capacity to aid in determining the real mental state of the prisoner." With such men as experts, it would have made little difference how they were appointed, whether by the court or by the opposing counsel; for their independence and integrity as the representatives solely of science would have assured the court of a high and unbiased opinion. If all so-called experts were of this character, no exception could be taken to the present method of securing them. These five gentlemen, though summoned there by the opposing sides, really constituted a commission, a single body, for the examination and determination of the sanity of the prisoner. The District Attorney allowed them to confer freely together, and permitted those for the defense to have complete access to all the facts and information in his possession in regard to the case. In other words, these five experts, after the manner of a commission, tried Czolgosz first in regard to his mental condition. This having been decided to be not abnormal, the case was remanded, as it were, for a civil trial, and no further medical testimony was introduced before the jury. "This course on the part of the District Attorney," Dr. MacDonald well says, "marks a new departure in the methods of getting expert evidence in criminal trials where the question of mental responsibility is involved, which is to be highly commended as a practical measure, tending to eliminate much superfluous testimony, and at the same time to minimize the danger of contradictory expert opinion." Hence, the absence in this trial, of all unseemly debate upon technical matters in open court, and the smoothness, so far as the medical side of the case was concerned, with which the "machinery of justice" moved.

In the Czolgosz trial, the objectionable method of allowing the experts to be appointed by the opposing counsel and then compelling those experts to debate, as it were, in open court before a body of uninformed laymen was, by a most happy confluence of circumstances, saved from eventuating into a display of temper, bias, and misconception, which is now all too common in our courts, and which has brought all expert testimony into more or less disrepute. It has been shown in this trial how desirable it would be to adopt some other method than the present one for securing expert testimony, and thereby to obtain always the result which in this case followed a fortunate but unlooked-for set of circumstances.

In view of all this, I am surprised at the statement made by Dr. MacDonald that "in view of the great importance of the case it is regrettable that no experts were called to testify on the trial as to the prisoner's mental condition, in order that it might appear on the record of the trial that his mental state was inquired into and determined by competent authority."

As the experts in this case were unanimous in their opinion, the introduction of their testimony in open court would not have done any harm; but it would have been a procedure which would have been a continuance of the very one which this trial has shown so magnificently it would be desirable to avoid. Moreover, the reason given by Dr. MacDonald for such a procedure seems to me to be quite inadequate. The medical examination, like many other things done before and after the trial, is sufficiently recorded and is now a part of history. After the decision of the experts, Czolgosz was brought before the jury as a sane man, to undergo his trial like any other sane man. There was no further question in the case in regard to his mental status, and it therefore would have been about as relevant to introduce any medical questions in regard to his mentality in the trial as it would have been to introduce the fact that he didn't speak the Chinese language and that he wasn't a Fiji Islander.

The very thing that Dr. MacDonald regrets is, it seems to me, the very thing that added to the unique and commendable character of this trial, namely, the total exclusion of all medical testimony (technical testimony in regard to the prisoner's sanity) from the court room. Even "in view of the great importance of this case," it seems to me that it would have been unwise to have introduced any medical testimony in regard to the prisoner's mental status after it had been unanimously decided by an acceptable and competent commission that he was not an insane man; for the setting of the precedent alone would have offset all the good that would have accrued from making an exception of this case. On several occasions, I have argued for the complete separation of the medical testimony in all such cases from the civil trial. (*Vide A Plea for the Medical Expert*, *Journal American Medical Association*, 1892; *idem, Magazine of Current Topics*, March, 1894; *Popular Lunacy*, *Journal American Medical Association*, April 18, 1896; *Insanity in Court*, *ibid.*, September 26, 1896.)

A criminal is sane or not sane. He may be feigning insanity. As a result of the periodicity of the disease, he may have been insane at the time he committed the crime, and yet sane in the legal sense, both before and after it. These are all questions requiring experience, special knowledge, and keenness of judgment to decide. Even in the grosser forms of insane manifestation it is not always an easy matter to come to an opinion; much less so is it in those forms which are close upon the border line. Therefore, if a criminal is suspected of being insane or if such a plea is made for him or he is thought to be feigning insanity, the open court in the presence of a body of non-medically trained men is not the place to discuss and decide so fine a question. Nothing, it seems to me, is more self-evident than that a commission, appointed by the court, or, better still, by agreement between the opposing counsel, as was done in the Czolgosz trial, should first examine into the mental state of the defendant, and then, in accordance with the decision of that commission, the man should be sent to an asylum or remanded for civil trial. But under no circumstances after he has been thus declared sane by competent authority should any further question as to his mental state be introduced into the course of the trial. This, it seems to me, is not only reasonable, but it is the only way that expert testimony can be made use of most effectively by the court, and can be saved from falling into a most unfortunate and unwarrantable disgrace. Of course, it is to be admitted that such a proceeding amounts to a sort of preliminary trial, and appears to upset the great principle so dear to the legal heart, of a man being tried by his peers. As a matter of fact, a man's peers are those whose capabilities are such that they can fully appreciate all the attendant circumstances with which he is or has been concerned. This is just the weak spot in the great principle of trial by jury, and its weakness is made especially glaring when expert testimony is brought into the question. The average jury is not a man's peers, when that man stands in the place of or for something quite outside of the capacity of that jury to understand. If a criminal is insane, he stands as the representative of the abstract idea of insanity, and the learned expert who has examined him represents for the time being also the abstract idea of insanity. The former is insanity *de facto*, so to say; the latter is insanity *de jure*. Both are for the time being representing something which is quite beyond the ignorance and inexperience which are represented in the intelmedical expert, but this particular case of the [illegible] ary. Therefore, a case [illegible] report [illegible] being tried [illegible] brought before a body of competent [illegible]. The spirit and purpose of the great principle of trial by jury is more nearly served, it seems to me, when a jury of experts [illegible] in a case involving the need of expert [illegible]. I submit, therefore, that such a procedure [illegible] more nearly in the spirit of a trial by jury than is the present method of trying such cases. With such a jury of experts [illegible] there would be, I have no doubt, a marked diminution in the number of pleas of insanity [illegible] brought into court.

The [illegible] trial mentioned [illegible] each to the honor of the court and the dignity of its own procedure that in the happy [illegible] of all medical opinion in a court [illegible] from the [illegible] in regard to the mental [illegible] of the prisoner after an expert [illegible] the [illegible] of medical experts had pronounced the defendant sane.

Progress of Medical Science.

The Boston Medical and Surgical Journal, Jan. 16, 1902.

Auscultation of the Knee-Joint.—William Ernest Blodgett auscultates the knee-joint by means of a full-sized Bowles stethoscope, with a soft-rubber cap sprung over the diaphragm. Of joint sounds proper, excluding skin and muscle sounds, he discriminates three kinds: the first and commonest is a snapping, creaking sound; the second, a grating sound, coarser, rougher, and usually less discrete than the first; the third is a squeak. Paralysis and general anesthesia apparently do not alter the joint sounds. Three knees with effusion gave no sound at all. In rheumatoid arthritis with atrophy of cartilage the sounds were the coarsest and roughest of any, becoming finer with improvement. In a case of osteoarthritis the sounds were not harsh. The single conclusion which the author thinks warranted by his observations is that joint auscultation deserves further investigation.

The Vagus Reflex.—Thomas J. Mays reports eight cases illustrating a phenomenon which he calls the vagus reflex, and which is characterized by peculiar symptoms produced by pressure on the pneumogastric nerve. These in some cases are nausea and vomiting, cough, pain, and discomfort in the chest, tingling, sweating, and coldness in the arm, fulness in the head with tendency to unconsciousness, occipital fulness and pain, faintness, dyspnœa, and helplessness of the whole body. Silver injections over the vagus relieved and abated the whole abnormal condition in every case. There was no marked pulmonary lesion in six of these cases; but to those who have paid attention to the relations which exist between vagus pain and pulmonary disease, the author thinks, it is quite clear that the former is frequently a premonitory symptom of the latter, and may therefore be regarded as an important diagnostic sign and a therapeutic indication in disease of the respiratory organs.

Needless Laparotomies, with a Report of Eight Cases.—John C. Munro reports cases in which no surgical lesion could be discovered at the time of operation, in spite of the fact that the symptoms, so far as they could be analyzed, led definitely to a diagnosis of some grave surgical trouble within the abdomen. These include a case of acute phosphorus poisoning, supposed to be septic peritonitis; hypertrophic cirrhosis, supposed to be septic peritonitis; acute nephritis mistaken for acute inflammatory process within the abdomen; nephritis, for appendicitis; alcoholism, for pancreatic or other acute intra-abdominal inflammation; alcoholism and morphinism, for rupture of kidney or intra-abdominal hemorrhage; obesity, for supposed tumor of the kidneys; and an unexplained condition which was thought to be pancreatic cyst. The symptoms were in all the cases absolutely misleading, and the author while regretting that he was led to operate, thinks it likely that under similar circumstances he would repeat the procedure.

Journal of the American Medical Association, Jan. 18, 1902.

Cases of Sarcoma and of Hodgkin's Disease Treated by Exposure to X-Rays.—A preliminary report is given by W. A. Pusey. In one case, a round-celled sarcoma of the neck seemed to be completely dissipated. A second patient having osteosarcoma of the shoulder was relieved as to pain, but not otherwise improved. A third case, sarcoma of right pectoral muscles and shoulder, showed a similar result. Two cases of Hodgkin's disease showed great reduction of the lymphomatous masses.

Consideration of Some Important Subjects Connected with the Treatment of Pneumonia.—E. J. Wells regards [illegible] treatment according to the following plan: [illegible] with a [illegible] blood [illegible] give fluid food, give digitalis and suprarenal extract in adequate doses. By these procedures from 5 to 10 per cent. of the toxin in the blood stream is removed, and that which remains is very considerably diluted, the excretions are stimulated, the [illegible] increased, the bodily tissues are [illegible] and their waste products are speedily removed, the heart, instead of vainly beating against a partial [illegible] is [illegible] by [illegible] a normal [illegible]. A second bleeding later in the course of the disease, [illegible] may [illegible] turn the tide toward recovery. If there is no leucocytosis (a state which the author regards as desirable and necessary in the malady) he believes it may be induced by nuclein acid, which may also be of service in preventing cardiac and vascular thrombosis. He is in favor of antipneumococcic serum, though his experience is too limited to afford him very reliable data. He advocates the free use of chloride of sodium in food and by enema. The bowels should receive attention, and any evidence of sepsis in the shape of a fetid diarrhea calls for salol. Oxygen inhalations should be begun as soon as the breathing begins to be rapid and shallow.

The Pontobulbar Heat Center.—E. T. Reichert reports a series of personal experiments from which he concludes that the effects caused by sections of the caudate nuclei, crura, pons, and bulb, show that thermo-accelerator centers exist in both the caudate nuclei and the pontobulbar region. He says that the cause of the rise of temperature when the caudate nuclei are injured is to be found essentially or solely in an excitation of a thermo-accelerator center, because similar irritation of parts in front of, above, and beneath, does not give rise to any noticeable increase of temperature, as they should if the nuclei merely represented a pathway of thermo-accelerator fibers to or from these parts. Starting with the caudate nuclei as a point of origin of efferent thermo-accelerator fibers, it is evident that in order to reach the thermogenic tissues they must run through the crura cerebri, pons, and bulb into the spinal cord, and that their irritation at any point along this course might be followed by an increase of temperature providing that shock, vasomotor disturbances, etc., did not interfere; moreover, that irritation of this thermo-accelerator pathway should cause a less marked increase than when the thermo-accelerator center itself is irritated. The less marked and less rapid rise after crural section is logically to be attributed to one or more of three factors: (1) To the coincident irritation of hypothetical thermo-inhibitory fibers which run from the cortical centers to the pons and parts below; (2) To the probably more marked vascular disturbances due to the section being nearer the cardiac and vasomotor centers; (3) To the probable absence of thermo-accelerator cells from the crura. It seems justifiable to assume that the increase of temperature caused by the section of the crura is due to the irritation of the thermo-accelerator fibers, and that the rise is less marked than when the caudate nuclei are irritated, chiefly because of the absence of thermo-accelerator cells in the former. The author believes that our present definite knowledge concerning the heat centers may be summed up in the following propositions: (1) Specific thermogenic centers exist in the brain and spinal cord and these centers are connected with each other and with various parts of the body, especially with the skeletal muscles and skin, by specific afferent and efferent thermogenic nerves; (2) The centers in the brain are either thermo-accelerator or thermo-inhibitory; (3) The center in the spinal cord is a general or reflex center; (4) The brain centers probably affect heat production by acting upon the spinal center; (5) The spinal center when separated by section from the brain centers is able to maintain the normal standard of heat production; (6) The activities of these centers is largely influenced by the changes in the temperature of the blood, and by cutaneous impulses which are probably generated in the peripheries of the "heat" and "cold" nerves; (7) The caudate nuclei contain an important thermo-accelerator center; (8) The pons and bulb probably contain a thermo-accelerator center; (9) A thermo-inhibitory center is located in the dog in the first cerebral convolution posterior to and in the vicinity of the sulcus cruciatus, and that possibly another such center extends downward from the junction of the supra-sylvian and post-sylvian fissures to the posterior fissure; (10) There is no adequate evidence to lead to the belief that specific heat centers exist in any other part of the body than in those above noted.

New York Medical Journal, January 18, 1902.

The Conservative Treatment of Appendicitis and the Fallacy of the Starvation Cure.—J. H. Carstens makes a most emphatic plea for early operation in appendicitis. He says that the true conservative treatment consists in prompt operation, and that the starvation method of procrastination is vicious, and has cost many lives, because it is used as an excuse to dally with patients who should be promptly subjected to removal of the appendix. There are no cases "too late for early operation, and too early for late operation." Operative experience cannot positively tell us in a new case just what the local condition at a given time is. We see cases on the second, third, and fourth day, where we suspect a rupture has taken place, and still by cutting down we find adhesions. We can peel out the appendix and remove it with ease, when its wall is so thin that we know that in six hours it would have ruptured, and we should have had a serious infection, and our patient's chance for recovery would have been far less.

Implantation of a Gold Ball for the Better Support of an Artificial Eye.—L. Webster Fox refers to his first efforts in this direction six years ago. He has improved and perfected the method, which he describes as follows: The eyelids are kept apart by a speculum, the conjunctiva is then grasped above and to the inner side of the inner canthus, and the tissues are well pulled out. He then passes a Beer knife or a curved keratome through the tissues, somewhat obliquely and well down into the orbit; this opening must be made large enough to push the globe in the opening behind the tissues, conjunctiva, etc. This starts the opening, which is enlarged with curved scissors, separating the tissues from the cellular tissues around the orbit, thus giving him a large pouch into which the globe can be inserted. He has discarded glass and silver balls, and only uses gold balls of 11, 12, 13, and 14 millimeters in diameter. The gold ball is inserted through the opening and retained in place by a shell which is modeled after an artificial eye, and called a "conformer." There are three sizes for various-sized orbits. He closes up the incision with two stitches, then places the conformer over the buried ball, and by gentle manipulation on this metal rotates the ball into place. The circular opening in the conformer allows the gold ball to fit the space which will be covered by the cornea of the artificial eye. The eyelids are then closed over the conformer, which is left in place twenty-four hours. The eyelids also help to keep the ball in place. These conformers are made of metal, gold-plated. The author says that the results obtained by this method are perfect; no secondary trouble follows, all healing up by first intention, and the two stitches are taken out on the third day.

Electricity in Renal Disease.—A. D. Rockwell reports five cases. He believes that electricity is of service in arresting inflammatory action and congestive pressure through improvement in circulatory drainage, increased filtration, and removal of the inflammatory products which block up the uriniferous tubules. By these measures, he holds, we can do much toward the prevention of more serious and chronic complications, and hasten recovery in those cases which have not yet crossed the border line of incurable organic changes. He has employed electricity according to the two following methods: First, *the high-tension faradic current.* Flexible electrodes, of blocked tin, three inches in diameter, and covered either with sponge or with layers of absorbent cotton, are placed over the region of each kidney and firmly bound. Beginning with *séances*, not more than ten minutes in duration, they may be very gradually or quickly increased according to the susceptibility of the patient, to three-quarters of an hour. The strength of the current should be gauged by the sensation of the patient, *i.e.* it should be given almost, but not quite, to the point of actual discomfort. Second, *the static-wave current.* This was used in connection and alternation with the high-tension faradic current. It has the advantage over the last-named of exceeding it greatly in frequency and tension; of enabling one to administer a current, not indeed of greater magnitude, but of far greater force and rapidity of oscillation, with the minimum of sensory and motor disturbance. Indeed, currents of the highest tension and frequency seem to have neither motor nor sensory effect at all appreciable, yet we find, as a result of these infinitely rapid vibratory disturbances, a marked influence on the circulation and combustion. On the circulation they have been found to lower the blood pressure at the moment of application, followed by increased pressure and vascularization. As a result, we get an active circulatory drainage of inestimable benefit in conditions of passive congestion. Rockwell believes that the current acts, partly at least, as a diuretic. In addition, it has an influence over metabolism, stimulating it and regulating disordered nutritive changes. In order to obtain this influence over general nutrition, we are obliged to combine with the local treatment by the high-tension faradic the older method of general faradization. This method is equally efficacious, according to my experience, in the condition under consideration, now that we have at command the high-tension coil, but is decidedly more tedious to both physician and patient.

Medical News, January 18, 1902.

General Medical Treatment of Syphilis.—G. Frank Lydston declares that the cardinal principle in the therapy of syphilis is that the physician should remember that he has to deal with three factors: (1) A specific disease to be controlled by specific medication; (2) A distinct individual personality in each patient; (3) The results of antispecific medication. The individual is too apt to be ignored in the treatment of syphilis. The general hygienic management of this disease is most important. Hot baths are very useful, for they increase the therapeutic action of mercury and iodide and limit their possible injurious effects. Attention to the bowels is very important. Digestive disturbance is a common result of the administration of antisyphilitic remedies and may be avoided by experimenting till that form of the mercurial salt is found which is adapted to the individual under treatment. Often when the patient does not tolerate the mercury and iodide well, the substitution of potassium chlorate is most happy in its results. Tonics also must not be overlooked. The general intelligence and therapeutic skill of the practitioner are important factors in the successful treatment of this disease.

Congenital Atresia and Stenosis of the Rectum and Anus.—W. Reynolds Wilson states that faulty development of the rectum and anus occurs in the new-born in the proportion of 1 to 10,000. The prognosis depends upon the character of the deformity and the opportunity for treatment. In the embryo the entoderm, which is the lining membrane of the gut, may be imperfect in its development and result in an incomplete formation of the canal. Forgue considers malformations of the rectum and anus either as instances of reversion in normal development, giving rise to permanent deformity, or as instances of aberrant development. The classification of the conditions in stenosis is dependent only on the degree of narrowing. As to atresia, the deformity may be more or less extensive. There are two chief types: one in which the absence of the rectum may be partial; second, there may be a total absence of the rectum with extensive obliteration of the gut and attachment of the cul-de-sac to the bony pelvis at the level of the sacro-vertebral angle. The evidences of stenosis and atresia depend upon the degree of malformation. In those cases in which the anus is pervious, the condition in the rectum is apt to be undetected until it is too late for treatment. The deformity may be discovered by exploration of the anal depression, by the absence of meconium, and by the general symptoms which always accompany these troubles, such as vomiting, abdominal distention, etc. The object of treatment is to establish, as far as possible, the normal anatomical relations. In cases of stenosis, gradual dilatation is indicated. In imperforation, two methods of treatment propose themselves: the opening of the rectum by perineal incision at the anal site; the establishment of an intestinal outlet by means of inguinal colotomy after the method of Littré.

American Medicine, January 18, 1902.

Obstetric Forceps in Relation to Tuberculous Lungs, Cardiac Anæmia, Etc.—George E. Abbott states that there are many cases of cardiac and tuberculous disease in which the patients date the commencement of their unfavorable or serious relapses to the time of having unwisely exposed themselves to an extra-physical strain, and he believes that the cause of many tuberculous mothers failing so markedly almost immediately after child-birth is the severe strain to which the lung tissue is subjected at this time. The writer thoroughly believes in the use of forceps as soon as the second stage begins. This will prevent all straining and will save many patients from an increase of heart symptoms or tuberculous troubles, and perhaps prevent an early death.

Purulent Tenonitis as a Complication of Typhoid Fever.—N. Zeltmayer reports the case of a soldier who developed a mild case of typhoid fever, but complicated by deep muscular abscesses. The writer was called to the case when there appeared a localized congestion of the conjunctiva and sclera over the insertion of the internal rectus muscle. Sodium salicylate and hot compresses were ordered. In two days the temperature rose, and three days later the inward and downward movements of the eyeball were limited, and there was diplopia in the [illegible] There was a [illegible] at the lower border of the [illegible] A [illegible] was made at this point and about half a drachm of pus [illegible] [illegible] no further growth. No [illegible] were made of the pus at any of the [illegible]

A Sugar-Forming Ferment in Suprarenal Extract; a Preliminary Report on Suprarenal Glycosuria.—Alfred C. Croftan describes certain experiments which he thinks reveal the fact that the injection of suprarenal extract can cause the production of glycosuria, provided the quantity injected is sufficiently large. Why in the case of one animal more must be given than in the case of another to produce approximately the same glycosuria is undecided and remains to be determined. The effect of the injections was transitory in all cases and all the animals recovered. The appearance of albumin in the urine in a few of the cases indicated some irritation of the kidney epithelium. The appearance of small quantities of bile-pigment in the urine of both dogs experimented on, and the local discoloration of the skin near the site of the injection, were suggestive in view of the pigmentary anomalies known to occur in disease of the adrenals, and the connection which exists between the destruction of [illegible] and the formation of pigments.

Philadelphia Medical Journal, January 18, 1902.

Decreasing Fecundity Concomitant with the Progress of Obstetric and Gynecic Science.—George J. Engelmann states that the birth rate in this country is lower than that of any European country excepting France, that the birth rate of the American-born population is much below that of France, and that the fecundity of the American woman is lower than that of women of any other country. A fact as gratifying as it is important is that it is not the American wife who reduces fecundity as much as it is the American husband. Many families who possess the best opportunities for rearing children have few or none. It is far oftener the women who bear children who retain their health than those who resort to measures to prevent conception or to destroy its product. A very fruitful cause of uterine and hepatic disorder is the unrelieved congestion of incomplete intercourse. The writer closes his paper by an appeal to obstetricians and gynecologists to do all in their power to stop the criminal practices which are the chief causes of decreasing fecundity.

Report of a Case of Paralysis Following Abortion.—Harry Morell reports the case of a woman aged twenty-nine who when three months pregnant started to flow, and continued to lose blood for six weeks. She went to bed for a time and then was about the house for about two weeks, although she suffered from severe pain in the back of her thighs. At the end of this time the fetus had to be taken away, but the placenta would not come even with instruments. A little later it came away spontaneously. The patient was in bed about two weeks after this, and when she was up again she complained of weakness in her left hip and a numbness and unnatural feeling from the waist to the toes. Gradually the right leg became paralyzed, and the patient had to take to her bed again, with absolute paralysis and muscular spasms of both legs. There was a pus tube on each side, and an oozing of pus from the cervix. She remained in bed for two years in good health, excepting the troubles just mentioned, after which there was a gradual return of sensation and motion, and at this time the patient is apparently well, although not robust. The writer concludes by saying that paralysis may occur after labor, abortion, or pelvic inflammation, paralysis after labor usually results from pressure neuritis, and that after abortion or pelvic inflammation is, or is likely to be, due to myelitis from infection. It is sometimes impossible to say clinically whether the disease is a neuritis or myelitis or both.

Outline of the Surgical Treatment of Acute Pancreatic Injuries.—B. E. Hadra declares that operative treatment of pancreatic wounds ought to begin as early and be as thorough as possible. The indications to be met are control of hemorrhage, avoidance of infection, prevention of escape of juice, repair of injuries, all of which in the nature of such cases will only be a part of the whole operative procedure. A stab or bullet wound from behind, when it is doubtful whether the pancreas is injured or not, will require at least good drainage through its tract. When there is an injury extending through the posterior parietal peritoneum, or if it is suspected, a regular high laparotomy ought to be performed at once. If the injury is received from the front so that a wound of the pancreas is possible the abdomen ought to be opened irrespective of other indications. All [illegible] [illegible] [illegible] The various [illegible] [illegible] Whenever local [illegible] there should be instituted a combination of anterior and posterior drainage. If [illegible] it would seem proper to open or reopen the abdomen and to attend to the pancreas. In this way an infective peritonitis may be aborted. The digestive power of the pancreatic juice must always be remembered. The [illegible] of the blood vessels is also of the greatest importance, and if required they must be ligated.

The Lancet, January 11, 1902.

Some Figures as Regards Susceptibility to Revaccination.—J. W. Anderson gives figures concerning 158 authentic cases. He classifies the results under three headings: (1) Perfect vaccinia, i. e., large, well-formed vesicles resembling those of primary vaccinia in all respects save that the process was often accelerated by a day or two; (2) Imperfect vaccinia, i. e., the production of vesicles, small, imperfect, and generally much accelerated; and (3) Negative result, i. e., transitory redness without the formation of any vesicles at all. The gross results of the 158 cases work out as follows: Perfect vaccinia, 72 cases, or 45.57 per cent.; imperfect vaccinia, 65 cases, or 41.14 per cent., and with a negative result, 21 cases, or 13.29 per cent.

An Unusual Complication of Influenza.—J. G. Carruthers' patient was a healthy man, thirty-four years of age, of good physique and good habits. The disease progressed in the usual manner for twenty days, when a quantity of venous blood was passed per rectum, each evacuation consisting of about a pint. This continued at three-hour intervals for thirty-six hours, when it ceased. Acetate of lead and opium were administered. The immediate effects of the hemorrhage were recovered from, but the patient died nine days later from exhaustion resulting from influenza. At the time of the hemorrhage the idea of a perchloride injection occurred to me, but in default of localizing any lesion, it also occurred to me that general peritonitis might be set up by an injection, so opium and lead wash was preferred.

A New Method of Breaking Down Adhesions.—The method described by G. W. Ord consists in fixing the part above the stiff joint, by means of the surgeon's left hand, to the bed or the table, and then quickly flexing or causing movement in the joint. The following special directions are given: *The shoulder-joint (right).*—For these manipulations the surgeon stands behind the patient's head. The patient lies flat on his back on a mattress, and the surgeon's left hand being placed flat on the clavicle of the affected shoulder, he pins the patient to the mattress or the table, preferably to the latter, the operator's free hand then grasping the elbow, raises that joint quickly to a level with the shoulder-joint. *The wrist-joint.*—The patient's forearm is placed on a table in the supine position. The surgeon's left hand pins down the forearm to the table, while his right, grasping the patient's hand, quickly flexes it to a right angle. *The finger-joint.*—This joint is treated in a similar way, the hand being placed on the table with its palmar surface upward. *The knee-joint.*—The patient lies *prone* on the bed. The surgeon's left hand pins down the thigh, while his right, grasping the leg above the ankle, quickly flexes the knee.

Acute Suffocative Pulmonary Œdema.—After a general description of the condition illustrated by two clinical histories, J. Lindsay Steven differentiates the affection from pulmonary embolism, acute spasmodic asthma, uremic asthma, and the acute pulmonary œdema sometimes following the removal of a large pleural effusion by paracentesis thoracis. Concerning treatment, he says that, on account of the great dyspnœa and the overpowering sense of suffocation caused by the continuous flow of fluid from the trachea into the mouth, the stimulants are better administered hypodermically and by the rectum. An ounce of brandy may be injected into the rectum diluted with an ounce or two of water or beef-tea. At the same time, a hypodermic injection of strychnine ($\frac{1}{30}$ gr.), and of digitalin ($\frac{1}{100}$ gr.) may be administered. The patient should be kept absolutely at rest in the sitting posture. A sinapism over the præcordium is of assistance, and the extremities should be kept warm by hot bottles. Opiates in any form are to be avoided as tending to prevent the expulsion of the œdematous fluid from the pulmonary alveoli. The injections may be repeated, if necessary, in three or four hours. If the patient is able to swallow, diffusible stimulants such as sal volatile are certainly to be recommended, and small quantities of milk, beef-tea, and brandy from time to time. The propriety of blood-letting also suggests itself in considering the treatment of acute suffocative pulmonary œdema, and is favorably spoken of by Dieulafoy. The blood may be taken either at the arm or by wet-cupping of the chest. The depression and collapse, however, are frequently so extreme that one hesitates to deplete.

British Medical Journal, January 11, 1902.

Typhoid Fever in the Inoculated.—C. Birt gives the mortality of uninoculated individuals who have suffered from typhoid fever as 14.25 per cent. During the same period 263 who were inoculated with typhoid vaccine, for the most part six to eighteen months previously, contracted this disease. Of these 6.8 per cent. died. The writer adds that it must be remembered that immunity against this disease is not readily established in some.

Epidemic Catarrhal Jaundice.—Eliot Curwen describes his observations of epidemics in Pekin and Tientsin. Most of the patients complained of great weakness and of some shortness of breath; there were general anorexia, a feeling of abdominal distention and nausea, and constipation with pale motions was the rule; diarrhœa occasionally occurred. Only four complained of pruritus. Many had some degree of fever with shivering. As a rule the icteric tint of the conjunctivæ was first noticed the day before or the day after the fever disappeared. The affection, according to the observations of the writer, cannot be very infectious.

Carcinoma and Malaria.—J. S. Davidson concludes as follows: Cancer seems to be a disease of locality rather than of race, and it is probably due to a microorganism. It does not appear to be prevalent in warm regions. A large malarial mortality is associated with a low cancer death rate. There is no evidence to connect it with food nor with excessive consumption of meat. It is a disease of cold climates, and it would appear to be most fatal in damp, cold countries associated with a clay soil, along the banks of rivers which are liable to overflow. The writer states that he has heard of a case of death from cancer of the stomach in a European who was stated to have suffered from frequent attacks of malarial fever.

Hydroa Gestationis Due to Staphylococcus Albus.—Nathaniel W. Holmes and W. Bulloch report the case of a woman, aged twenty-six years, who, on the day following the delivery of her third child, was annoyed by a rash which broke out on various parts of her body. There were redness and itching, but the temperature was normal. Bullæ formed and the fluid contained in them was examined; it proved to be a pure culture of staphylococcus albus. It was discovered that the patient at the age of thirteen years had a very badly poisoned foot and leg from a brass rivet in her boot. About the same time she had diphtheria. At each of her previous confinements she suffered from the same eruption as this one reported. The patient recovered, and the infant, who took the mother's milk from birth, was quite free from any rash.

Note on a Method of Quantitatively Estimating the Phagocytic Power of the Leucocytes of the Blood.—W. B. Leishman describes the aim of this method as the enumeration of bacilli or cocci phagocyted within a definite time by multinuclear cells of the blood under examination, obtaining an average of these values, and comparing the result with that of a control blood, preferably that of the observer, examined under identical conditions. A certain amount of the blood to be observed (5 c.c. is convenient) is mixed with the same amount of an emulsion of the culture of the germ which is being investigated. One drop of the resulting mixture is taken for the experiment and spread on a glass slide and covered with a cover glass. The same amount of control blood is placed on the same slide under another cover glass. After an arbitrary time, half an hour for example, during which the slide is placed in a moist chamber, and left in an incubator at 37° C., the films are dried and stained and compared. So far the results show that the patient's phagocytic power, as gauged by the control blood, has varied in direct proportion to the amelioration of his symptoms. The patient under consideration had been afflicted with boils, and had been given staphylococcus vaccine hypodermically.

Deutsche medicinische Wochenschrift, December 26, 1901.

Plasmotropic Toxin Formation in the Body.—E. Grawitz says that, under certain conditions, poisons may be introduced or arise within the body which exert a deleterious influence upon the red blood cells, causing in them a granulation degeneration, but not their complete destruction. In this manner the cells of the liver, spleen, and bone-marrow may fail to receive proper nutrition, and undergo extensive degeneration. In many of these cases the hæmoglobin is changed to methæmoglobin. Such a process is described as "plasmotropic." If the deleterious action upon the red blood cells is carried further, their complete disintegration results, and the process is designated "plasmolytic." Certain poisons in small doses are plasmotropic, and in large doses plasmolytic. An example of such is pyrodin. Other substances, such as lead, never in any dose exert other than a plasmotropic action. Plasmotropic degeneration of the red blood cells occurs in patients who suffer from intestinal hemorrhages from various causes, such as ulcus ventriculi, carcinoma ventriculi, and cirrhosis of the liver. By experimental work, Grawitz has shown that this is due to poisons formed during the passage of the blood through the intestinal canal. Animals to whom blood was internally administered failed to show plasmotropic degeneration, but the same was easily produced in this manner in human beings. Identical results were obtained by the administration of certain therapeutical preparations of hæmoglobin. It is thought that in the same manner are to be explained the blood degenerations brought about by various intestinal autointoxications.

The Anti-Bodies of the Blood.—P. Ehrlich enters into an exhaustive consideration of his theory of immunity. In accordance with the fundamental principles of cell physiology and pathology as laid down by Virchow, it is certain that the normal protective bodies of the blood and those artificially produced as the result of infection are entirely similar in their mode of origin. In regard to the formation of the latter, so far as antitoxin is concerned, two views have been advanced: First, the hypothetical metamorphosis of toxin into antitoxin, and, second, the secretion theory. According to the first view, antitoxin is nothing but a toxin so changed that it has become non-poisonous. This is brought about through the activity of a substance called "alexin." Many facts render this view untenable. In the first place, the antitoxin produced in the body as the result of the introduction of toxin, is, in amount, out of all proportion to the latter, being in many cases 100,000 times greater than this. Furthermore, the fact that in normal animals antitoxin is often present, shows that such can be produced by the body itself without the assistance of any toxin. The satisfactory explanation of the identity of these normal and artificial processes forms one of the chief points in favor of the "side-chain" theory. The explanation of this theory is best accomplished by considerations of diphtheria antitoxin. If we take a given quantity of such antitoxin, and in a series of experiments add to it different diphtheria toxin bouillons, we find that it neutralizes, in various cases, different quantities of this bouillon, and that the quantities so neutralized previous to neutralization possessed a different toxic power. This proves that whatever laws govern the neutralization of toxin by antitoxin, they do not apparently follow those of ordinary chemical equivalence. If we take a given portion of such toxic bouillon, having previously ascertained its toxic power and the quantity of antitoxin necessary to neutralize it, and preserve it for a certain time, we find at the end of this time that it requires the same amount of antitoxin to neutralize it as it originally did, but that its toxic power has been markedly reduced. This shows that the toxin contained two substances or groups of substances, one of which was concerned in the neutralization process, and was stable, while the other constituted the toxic property, and was unstable, being very much reduced in amount the longer the bouillon was preserved. The first of these is called the "haptophore" group, and the second the "toxiphore" group. "Toxoids" are such as have retained their haptophore group, but entirely lost their toxiphore group. The presence of such toxoids accounts for the apparent violation of the laws of chemical equivalence above noted. Two facts show that the haptophore group is concerned in the antitoxin formation. First, toxoids are abundantly able to produce antitoxin, and, second, toxins whose haptophore group is already used up are no longer able to produce antitoxin.

It is now necessary to consider the functions of the living organism in the formation of antitoxin. It is a firmly established law that chemical substances introduced into the body act only upon certain cells. In other words, certain cells of the body show a predilection for certain substances. Among such may be mentioned morphine, atropine, strychnine, and digitalin. Furthermore, such substances do not enter into firm chemical combination with the body elements, but are found stored up in the cells which show a predilection for them, and may be extracted from these by various processes. According to this, the possibility that certain substances may enter into such union with the albumin molecule cannot be denied. This is also to be applied to the nutritive processes of cells, which accordingly are to be considered as a synthetic process. In accordance with this idea in living protoplasm, there are numerous groups called "side-chains" or "receptors," which possess a maximum affinity for certain nutritive substances, and by means of which such substances are retained and anchored to the cell. These receptors are multitudinous in number. Now the haptophore group of the toxin molecule, being independent in character, acts as a nutritive substance, finds its receptor in the protoplasm of the cell, and thus anchors the whole toxin molecule to that cell. In this manner the cell is brought under the deleterious influence of the toxin. If the influence upon the cell of the toxophore group of the toxin molecule is not too severe, a regenerative process, in accordance with a universal law in nature, is set up, and the haptophore receptor, having been used up in the process, is replaced. By a continuation of this process, there finally comes a time when the haptophore receptors are so abundantly produced that they can no longer be retained in the cell, and they pass into the blood. When this takes place, they seize the toxin molecule in the blood, and prevent its entrance into the cell where it can do harm. Accordingly, immunity to toxins is entirely dependent upon the amount of haptophore receptors in the blood. Of course, it is to be understood that the toxophore group of the toxin molecule also finds its receptor in the cell protoplasm, but this is not concerned in the production of immunity, as it is soon disposed of by the poisonous action of the toxophore.

When we consider the questions of hæmolysis and bacteriolysis the conditions become very much more complicated than those just described in connection with antitoxin formation. For the solution of these questions the study of hæmolysis offers the greatest advantage. Horses, when inoculated with the blood of rabbits, produce a serum which destroys the blood cells of the latter animals. When such serum is heated to 55° C., it loses this property, but regains it when certain normal sera are added to it. From this it is seen that in hæmolytic sera two substances are present, one of which is present in the immune sera and is stable, and the other is present in the normal sera, being unstable and easily destroyed by heat. The first of these is called the "immune body," and the second the "complement." By experimenting with sera which contain only the immune body or the complement it is shown that the red blood cells are not able to take up the complement when it is present alone, but only when the immune body is also present. Nevertheless, they take up the immune body when it is alone present, this, however, does not produce hæmolysis. It is thus seen that the immune body is the factor which anchors the complement to the red blood cell. Ehrlich believes that this immune body possesses two kinds of haptophore groups, one of which becomes united with its receptor in the cell, and the other binds the complement to the cell. In order to express this double action of the immune body, he calls it the "amboceptor." The complement possesses a constitution analogous to the toxin. It has a haptophore group, by means of which the amboceptor unites it to the cell, and through which anticomplements are produced in a manner entirely similar to that in which antitoxins are formed; it also possesses another group which is the analogue of the toxophore group of the toxins, and which brings about the destruction of the red blood cell. The action of this group is called "zymotoxic." Bordet does not agree with this view, and holds that the immune body and complement do not unite, but that the former makes the red blood cell accessible to the action of the latter. This is not conceivable, because red blood cells do not possess complementophile groups under any circumstances. Furthermore, his theory does not explain why an immune body arising from a given animal exerts the most influence when the serum of an animal of the same species is added to it. According to his theory, it should make no difference what kind of a complement is added. The amboceptor theory, however, fully explains this, for a given amboceptor would, of course, unite most readily with its own complement. Bordet also holds that the complements are a unity. Experimentation, however, has shown that they may be of very many kinds. In regard to the origin of the immune body and complement, it is certain that such is cellular. The first are receptors of high molecular composition. Their abundance in the blood in immune sera is brought about in a manner entirely similar to that given for antitoxin receptors. The complement is to be regarded as a normal cell secretion. The origin of agglutinins and precipitins, and all other protective bodies, is entirely similar in character to that of the immune body. A consideration of this "side-chain" theory shows that the protective bodies of the blood owe their formation to processes identical in character to those of physiological nutrition. This is entirely in accord with the fundamental principles of cellular physiology and pathology.

Deutsche medicinische Wochenschrift, January 2, 1902.

Diagnosis of Pernicious Anæmia by Hæmatological Methods.—Emil Körmöczi considers the diagnosis of this disease after the methods laid down by Ehrlich. The latter maintains that the blood of pernicious anæmia is always characterized by the presence of megalocytes and megaloblasts. In the blood examinations of a large number of cases of secondary anæmia associated with nephritis, carcinoma, amyloid degeneration, tuberculosis, etc., Körmöczi has never found megaloblastic cells. In some instances, however, such cells were found in the marrow taken at autopsy. He has observed fourteen cases of pernicious anæmia, of which he reports five because they were fatal, and post-mortem examinations of the marrow were made. In three of these no megaloblasts or nucleated red blood cells were found in the blood during life. In all of them macrocytes, megalocytes, and megaloblasts were found in the marrow post mortem. As the result of his work he believes that the hæmatological picture of pernicious anæmia is in many cases not to be differentiated from that of secondary anæmia; nevertheless, the marrow in this disease is always of the megaloblastic type. In pernicious anæmia, macrocytes are more characteristic and more abundant than megaloblasts; nevertheless, their presence is not diagnostic of the condition, but must be supported by other hæmatological appearances and characteristic clinical symptoms.

Glycolysis.—Ernst Bendix and Adolph Bickel oppose the theory of glycolysis advanced by Lépine, who ascribes the transformation of glycogen into glucose to the activity of a glycolytic ferment present in the internal secretion of the pancreas and absorbed from that organ into the blood. In order to establish the validity of Lepine's theory, three sources of error must be excluded: (1) Errors in the methods of sugar estimation. (2) The decomposition of glucose by bacterial activity. (3) The decomposition of sugars by purely chemical (not fermentative) processes. In regard to the first source of error it may be said that the researches of Schenk, Bickel, Leo, and Bendix have shown that quantitative sugar estimations in fluids containing albumin, such as have been employed in all glycolytic experiments, are far from being exact. It is true that the action of bacteria may be excluded by the use of antiseptics, yet in the work hitherto done, no such precautions have been satisfactorily taken. So far as the chemical decomposition of sugar is concerned, Bendix and Bickel have shown that in pure aqueous soda solutions (0.2 per cent. to 0.5 per cent.) at the body temperature, glucose is markedly decomposed. Their results were obtained by the use of the reduction methods of Pflüger. In view of these facts it can only be said that in our present knowledge the supposition that glycogen is transformed into glucose by the activity of a glycolytic ferment is merely interesting speculation.

Treatment of Chronic Dysentery by Temporary Colostomy.—A. Nehrkorn reports a case of chronic dysentery upon which, as a last resort, colostomy was done, and satisfactory results were obtained. The disease was of about nine months' standing, and had been subjected to all known medication without avail. At the time of the operation the general condition was of the worst, the hæmoglobin being reduced to about 30 per cent., and the number of red blood cells to 1,800,000. Upon operation the sigmoid flexure was found to be œdematous, markedly infiltrated, and its internal surface covered with a layer of slimy, fibrin-like mucus. Several ulcers were found therein which bled freely upon slight provocation. An artificial anus was established, and through this the colon was washed out daily with a weak solution of salicylic acid. Following the operation the general condition markedly improved and the dysenteric lesions gradually disappeared, so that in about seven weeks complete recovery had practically taken place. Three and one-half months after the operation a second operation was performed for closure of the artificial anus. This was likewise followed by good results. This case is of interest from the fact that operative procedures as a means in the treatment of dysentery are practically unknown, and their recommendation has not been given a place in literature, yet it is here seen that even in the last stages of this disease such are of great utility, and life may be saved thereby.

Münchener medicinische Wochenschrift, December 24, 1901.

Immunity.—Dr. Weichardt reviews the various theories of immunity and enters into a detailed consideration of the various steps which have led Ehrlich to proclaim his well-known "side-chain" theory. The researches which have been conducted with respect to the "immune bodies" have shown that in different infections such are produced in different locations. In typhoid fever and cholera the "immune body" is formed in the blood-forming organs, while in pneumonia it is produced in largest amount in the bone marrow. In accordance with this fact, just before the crisis in pneumonia the marrow corpuscles are increased in the blood. In the use of antitoxic sera the combination between such sera and the toxin follows the law of multiple chemical equivalence, but in the use of bactericidal sera such is not the case. This accounts for the greater activity of antitoxic sera as against that of bactericidal sera. Notwithstanding this fact the latter have been used with advantage as is evidenced in the results obtained with plague antiserum in India.

Uterine Lactation Atrophy.—L. Fraenkel agrees with Thorn that lactatimatrophy of the uterus may be either a physiological or a pathological process. In his experience, however, pathological uterine atrophy is much more frequent than Thorn considers it to be. In all cases of physiological atrophy of this organ complete regeneration has taken place previous to the seventh month following delivery, and all cases which show atrophy after this time are to be considered as pathological. In order to make the diagnosis between physiological and pathological atrophy it is necessary to examine the uterus frequently between the third and seventh month following delivery. If it is found that during this time regeneration is in progress, it may be assumed that the atrophy is physiological, otherwise it should be decided that a pathological process is present. Thorn thinks that physiological atrophy first begins to regenerate after the cessation of lactation, but it is certain that this form of atrophy is always regenerated previous to this time. Thorn in answer to the above says that statistics show that uterine atrophies which are not eventually completely regenerated, and are thus to be considered as pathological, are very rare, and that a differentiation between the physiological and pathological process on the basis of the time of complete regeneration after delivery cannot be made. He cites numerous instances to substantiate this statement.

Münchener medicinische Wochenschrift, December 31, 1901.

Prolapse of the Urethra in a Girl Five Years of Age.—Dr. Bente reports a case of prolapse of the urethra in a female child five years of age. The general condition of the child had always been good, and no cause for the prolapse could be discovered except perhaps a condition of chronic constipation. The occurrence of periodical attacks of coughing was also possibly active as an inciting cause. The first symptom observed by the parents was a vaginal hemorrhage similar in character to that of a normal menstruation. Upon examination a tumor presented itself, bounded anteriorly by the clitoris and posteriorly by the hymen. Pressure caused slight pain, together with moderate hemorrhage from the external orifice of the urethra. The tumor was easily reduced and held in place by a catheter maintained in the urethra. Cauterization with nitrate of silver was also practised. After ample trial the results of this treatment were not satisfactory and a radical operation was performed. Complete recovery followed. This case is of special interest as showing that prolapse of the urethra is not uniformly associated with a poor general condition, but may occur in persons who are in the best of health.

Epidemic Conjunctivitis Due to the Koch-Week Bacillus.—C. Markus reports the study of 150 cases of this disease during the recent epidemic among children at Bitterfeld. Usually the first sign of the trouble is the appearance of a moderately abundant, yellowish-white secretion upon the conjunctivæ of both lids. At this time there is little or no congestion, but the upper lid is somewhat infiltrated. The secretion rapidly increases in amount and becomes decidedly purulent in character. Conjunctival congestion appears and rapidly increases in severity, both the palpebral and ocular conjunctivæ being affected. Both upper and lower lids become markedly œdematous. Subconjunctival hemorrhages are often present. A creamy purulent secretion is never present, and its absence forms the chief differential clinical sign between this disease and ordinary blenorrhœal conjunctivitis. Chemosis and membranous formations are also occasionally seen. This particular epidemic was characterized by the appearance of marginal phlyctenules early in the disease. These were usually multiple and not dependent upon the presence of a scrofulous diathesis. In most instances the disease ran an acute course as above depicted. A very few were observed in which the process was subacute from the onset, but a considerable number of cases were seen in which the course was chronic throughout. In the majority of instances the disease lasts from three to four weeks. Exceptionally it can be cured in from eight to fourteen days. Very often the acute cases subsequently become chronic and in this condition acute exacerbations are frequent. The specific bacillus is present in the secretion generally in great numbers. It may be present in pure culture or associated with various other bacteria, especially pneumococci. In cover-glass preparations it may be readily stained with dilute carbolfuchsin. It does not retain Gram's stain. The acute cases with abundant secretion are best treated by applications of a 2-per-cent.-nitrate-of-silver solution followed by irrigation with saline solution. The phlyctenules easily succumb to applications of yellow-oxide-of-mercury ointment. In chronic cases the lids should be touched with 1½-per-cent. lead solution.

Berliner klinische Wochenschrift, December 30, 1901.

Motility of the Lymphocytes.—Alfred Wolff substantiates the opinion of Hirschfeld that the lymphocytes possess an active motility. The latter, by the employment of Deetjen's agar saline solution, was enabled to observe such motility in the large lymphocytes taken from a case of lymphatic leukæmia. By the employment of the same method, Wolff has been able to ascertain the manner in which such locomotion is brought about. The formation of prolongations of the cell protoplasm is the first sign of motility observed. These are entirely similar to those seen in the well-known locomotion of amœbæ. Several facts show that this phenomenon of the lymphocytes is to be considered as typical amœboid movement, and not a form of degeneration. In the first place, polynuclear leucocytes show the same appearances, and it is generally conceded that in these such changes do not signify degeneration. Furthermore, it is known that the nuclei of cells do not stain with artificial dyes so long as these cells are alive, but that this is only possible after they are dead. By adding coloring matter such as methylene blue or neutral red to the agar saline solution, and introducing the large lymphocytes therein, it is seen that, except in a very few instances, their nuclei do not stain. That this non-staining is not produced by the viscidity of the medium in that this prevents the free access of the coloring matter into the cell substance is shown by the fact that under identical conditions lymphocytes known to be dead and blood plates are readily stained. It appears, therefore, to be established that in the Deetjen agar saline solution lymphocytes show characteristic changes of form, which signify slow locomotion, and that such changes are a living property of these cells, and are not indicative of degeneration. The large lymphocytes always show more motility than the small variety. For this reason the blood of lymphatic leukæmia is especially suitable for these observations.

Rhinitis Vasomotoria.—W. Lublinski describes this disease as occurring principally in anæmic and chlorotic subjects. It is seldom bilateral, but usually alternates from one side to the other. The mucous membrane of the nares is much swollen and congested, and frequently completely occludes the nasal passage. Especially is this the case in the early morning when the patient first awakens. This is accompanied by a thin, watery secretion, which decreases in amount as the day advances. The voice is nasal in tone and oftentimes dryness of the throat and slight cough and dyspnœa are complained of. The point of the nose and the upper lip are swollen and congested, as are also the alæ nasi. Upon examination it is seen that the mucous membrane of the affected side is swollen and more or less completely occludes the passage. This may be easily depressed by the sound, which shows that there is no increase in the connective tissue, and differentiates this condition from rhinitis hypertrophica. Constitutional measures are of importance in the treatment, and iron and arsenic should be freely given. As for local treatment, massage of the swollen cutaneous surfaces, with a sound moistened with menthol-paraffin (¼-½ per cent.) is of service. This should be repeated two or three times weekly, and each treatment should last from five to ten minutes. For the treatment of the swollen mucous membrane the use of the galvanocautery has been frequently recommended. When such is undertaken, anæsthesia should be produced by the employment of a 10-per-cent. eucain solution. Satisfactory results are often obtained in this manner, but the use of the galvanocautery is always followed by great discomfort of the patient, and in many cases seems unnecessarily harsh. The submucous injection of a 10-per-cent. solution of chloride of zinc is especially to be recommended, as it is very efficacious in relieving the tumefaction of the mucous membrane, and is not attended by any unpleasant sequelæ. If any hemorrhage takes place after the withdrawal of the hypodermic needle, this can be easily checked by the application of a few drops of antipyrin solution (10 per cent.). Usually such injections are followed by complete recovery in about two weeks. Occasionally a second injection is required.

Acute Pharyngitis of the Streptococcal Type.—Lewis S. [illegible] reports [illegible] cases which occurred in one week in [illegible] All were characterized by the presence of streptococci, a [illegible] of [illegible] symptoms, febrile phenomena, and the rapid disappearance of the pharyngeal [illegible] with all of the symptoms except severe exhaustion. The infection in all was of an attenuated type as regards both the general and local symptoms, and in this respect differed from the usual streptococcic angina as seen in connection with some of the acute infectious diseases such as scarlet fever with its angina as an essential part of the disease.

A Study of the Hereditary Effects of Alcohol.—J. M. French, from the statistics obtained from various sources, concludes that alcohol is the greatest cause of degeneracy, both mental and physical. When not an inebriate the subject is likely to be [illegible] degenerate, mentally unstable or unbalanced, fanatical, eccentric, or a genius. Inherited inebriety develops rapidly at the first exciting [illegible] The subject [illegible] a moderate drinker [illegible] a drunkard. [illegible] and the patient is apt to relapse. Of [illegible] children of alcoholics observed [illegible] [illegible] per cent. [illegible] By adding 171 [illegible] the percentage rose [illegible]

Purulent Ophthalmia of the New-Born.—[illegible] that the essentials in the successful management of purulent ophthalmia [illegible] the new-born [illegible] (1) Prompt and thorough application of [illegible] to cleanse the eye and [illegible] the action of pathogenic [illegible] (2) Intelligent and [illegible] (3) Attention to the physical condition of the patient. For the purpose of cleansing the eye, the most important feature of the treatment is [illegible] irrigation. [illegible] It should be frequently [illegible] In some cases the eyes [illegible] A solution of [illegible] per cent. [illegible] that can be used for irrigation. None of the newer [illegible] nitrate of silver.

Relation of Insects to the Spread of Disease.—Joseph McFarland [illegible] in which insects may aid in the dissemination of disease. (1) They may carry, from place to place, disease-producing micro-organisms which have collected upon their bodies and limbs and [illegible] directly by alighting upon wounds, and indirectly by alighting upon food stuffs. (2) Insects may carry within their bodies germs of disease which have entered with the food, and may subsequently be deposited elsewhere with the feces. (3) [illegible] blood-containing parasites from the bodies of diseased animals may carry them upon their proboscides to the next animal [illegible] directly and immediately infecting it. (4) Insects may take infectious germs into their bodies and transmit them to their offspring, whose bites are infectious. (5) Insects may take into their bodies parasitic organisms which there undergo a further development, the insect acting either as an intermediate or a definitive host, and transmitting the parasite to other animals in some chemical form in which they are infective. (6) The insects may become infected with pathogenic organisms, die, fall into food stuffs and thus impart infection to man.

[illegible]

Snake Poisoning in Central Africa.—Neil Macvicar reports three non-fatal cases in which the chief symptoms were local pain and swelling. He states that in the venom of all poisonous snakes there exists a constituent which has the power of destroying blood cells, and which also acts on the plasma, so that if introduced rapidly in a vein it causes extensive clotting, but if introduced slowly subcutaneously it destroys the normal coagulative power of the blood. It also acts on the capillaries so damaging them that they give way and allow of extravasation. This constituent is met with in only very small quantity in the poison of some colubrine snakes, while in the poison of Indian vipers it is present in sufficient quantity to produce marked hemorrhagic symptoms, these symptoms supervening after the patient has recovered from the earlier symptoms of prostration and paralysis. As to treatment [illegible] it is well to remove the damaged [illegible] tissue immediately beneath the fang marks. Permanganate of potassium may then be rubbed into the wound.

Amputation for Perforating Ulcer of the Foot in Lepers.—Edward Horner holds that this operation [illegible] good results and should therefore be performed in preference once for all [illegible] as far as possible [illegible] of lepers and give these patients another chance of [illegible] good health. He reports nine cases in which that treatment was followed. Less than amputation [illegible] no avail [illegible] and tendons has not given permanent relief. The patients were all operated on in 18[illegible] In five there has been no [illegible] in one not for eighteen months, in two not for [illegible] years, in one it returned. The general health in the last case was not improved, in two it was improved, in six much improved. A strong argument in favor of operation is the readiness now shown by the poor lepers to part with a portion or whole of an ulcerated foot. It is very noticeable how limited is the life of many of the lepers after they leave the asylum in Pakhoi, proving that good housing needed for ordinary complaints is a factor to be reckoned with in the treatment of this dire disease.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 16, 1902.

George L. Peabody, M.D., Vice-President, in the Chair.

The Treasury Department and Consumptives.—Dr. S. A. Knopf, the mover of the resolutions introduced at the last meeting of the academy, condemning the ruling of the Treasury Department, by which consumptives were excluded from our shores, made some remarks in further explanation of the motives that had prompted him to introduce these resolutions.

Dr. Andrew H. Smith said that to his mind this proposition to exclude consumptives from this country was unworthy of America, and he principally objected to this action of the Treasury Department because of its unnecessary cruelty.

Dr. Alfred Meyer said that it was not enough to adopt the resolutions; such action should be followed by an effort on the part of the Academy of Medicine to secure a different ruling on this point from the Treasury Department.

Dr. E. G. Janeway suggested that before action was taken on these resolutions, the Treasury Department should be asked for details concerning the ruling in question, and the statistics and reasons upon which it was based. It looked to him that the hardship arising from the present attitude of the Treasury Department had resulted from the action of one man without counsel having been taken with the medical profession.

On motion of Dr. Knopf, action on the resolutions was postponed until the next meeting of the academy, and the Secretary was instructed to ask the Treasury Department for the information desired.

Vacant Buildings Suggested for Consumptive Hospitals.—Dr. G. L. Peabody announced that he had received a communication from the present Commissioner of Charities, Mr. Homer Folks, asking for the advice of the academy regarding the advisability of using as hospitals for consumptives certain buildings recently vacated by the Manhattan State Hospital for the Insane.

On motion of Dr. Henry P. Loomis, the Chairman was requested to appoint a committee to consider this question, formulate an answer and report the same to the academy at its next meeting. The Chairman appointed on this committee Drs. H. P. Loomis, E. G. Janeway, and Alfred E. Meyer.

The Food Factor as a Cause of Health and Disease During Childhood.—Dr. Joseph E. Winters was the author of this paper. (Vide page 121.)

Dr. Leroy M. Yale said that the author of the paper had come to practically the same conclusions regarding infant feeding that he had himself reached; hence, he would dwell more particularly on certain everyday details. The reader of the paper had shown why the meat dietary so much in vogue was deleterious. In the well-to-do families one would find among the adults a vast deal of gout and rheumatism, and their children came into the world handicapped on this account. Such children, moreover, did not have the opportunity to expend their energy, as did the children of the poor who played freely in the street.

Dr. John Dorning said that it was not uncommon to find an infant of three months taking from half an ounce to an ounce and a half of beef juice daily. This practice seemed to him reprehensible. He agreed with the author that meat should not be added to the diet until about the third year. Milk and cereals constituted the proper diet for the child. One could not consider solely the chemical composition of a food stuff in determining whether it was fit or unfit for the child. He would place oatmeal at the head of the list of cereals for both children and adults. He preferred to give a child the whole wheat bread or a coarse bread containing some of the cortex of the granules. Whole meal contained about 15 per cent. of proteids, of which about 10 per cent. were soluble.

Dr. Thomas S. Southworth said that he had long been convinced that a great deal of the illness of children was dependent upon poor nutrition. The well-nourished child rarely fell a prey to disease. The foundation of good or bad health had often been laid before the child reached the period especially considered in this paper. The transition from a milk diet to a mixed diet was a critical period, and if not carefully supervised by the wise physician, the foundation for much ill health would probably be laid. He would prefer to have a child continue the use of the bottle to using a tumbler, because in the former case the little one would ordinarily take more milk, and milk should be the chief article of diet. He did not feel disposed to condemn meat juice so unreservedly as the author had done, as it often proved a valuable nutrient as well as a means of improving the quality of the blood. It was true, the mistake was often made of giving too much meat juice.

Dr. W. H. Bates said that from clinical observation of the effects of diet upon eye diseases, particularly among the poor, he had come to feel that the same diet would not suit all children. He gave examples of the varied effects of a meat diet and of a milk diet upon such children.

Dr. Elmer Lee said that the paper of the evening showed experience, investigation, and mature thought. Perhaps the kernel of the whole subject was to be found in the author's statement, that we must go to organic nature. It was common practice to make use of only a part of the good things provided by nature. The different varieties of flour attested this, for they represented only parts of the grain, and hence the consumers of these flours only received a part of the health, nature had intended for them. He thought that only such food as was in itself capable of germination was a safe and suitable food for either the child or the adult. The cereal was perhaps the best food, while meat was the poorest in nutritive value and the dearest to buy. The author had spoken of chemistry and physiology, but had said nothing about that comparatively new subject, electrical physiology. The various constituents of the food united to furnish the electrical energy. Attention had been directed this evening to the fact that the fluids of the tissues of the body were alkaline. Mr. Edison, in the construction of his latest storage battery, had made use of an alkaline battery fluid, whereas hitherto acid fluids had been used.

Dr. Winters closed the discussion. He said that the remarks of Dr. Dorning about the chemical composition of food giving but little idea of its nutritive value, reminded him of some of the proprietary foods on the market. He was sorry to say that many of the best recognized textbooks recommended one or more of these prepared foods, yet they were undoubtedly deprived of every particle of nutritive value by the chemical process to which they had been subjected in order to preserve them. The fact that they were given in combination with milk was what had given them their hold upon the public; it was the milk that nourished the child and not these foods—indeed, the latter were injurious. The speaker said he had been studying the various flours, and he had come to think that whole wheat flour was a common source of digestive derangement among the children in the best families of this city. He did not believe the children in this city were capable of digesting whole wheat flour, and Graham bread or any of those preparations which contain much woody fiber. He had seen a number of children entirely recover by simply stopping these articles of diet. His attention had been first directed to the use of meat juice for children, by the case of a child who was profoundly anæmic. This anæmia had begun with the substitution of beef juice for one feeding. The beef juice was discontinued, and she was put back on cereals. Without medicine the anæmic quickly disappeared, and since then he had repeated this observation hundreds of times, for it had been first made about [illegible] years ago. He believed there [illegible] of producing [illegible] to [illegible] the [illegible] of [illegible] years. A [illegible] from [illegible] and [illegible] of [illegible] milk [illegible] in [illegible] would [illegible] and [illegible].

NEW YORK ACADEMY OF MEDICINE

SECTION ON PEDIATRICS

Stated Meeting, January 9, 1902.

R. G. Freeman, M.D., Chairman.

Congenital Asymmetry or Hemihypertrophy in an Infant.—Dr. A. Hymanson presented this case. The patient was an infant of [illegible] months, born of parents who were not relatives. Measurements showed the right upper and lower extremities to be longer and larger than the corresponding ones of the other side. On October [illegible] the child was unconscious for twenty-four hours from some unknown cause, but it recovered perfectly. The cranium also appeared to be larger on the right side than on the left. The speaker said that he had been able to find only about a dozen cases of this kind on record.

Dr. S. H. Dessau said that he had seen a similar case some years ago, and had presented it to the Northwestern Medical and Surgical Society. It had been afterward referred to by the late Dr. J. H. Fruitnight as a case of congenital rickets. The case just presented, however, did not seem to exhibit any of the features of rachitis.

A Case of Spasmus Nutans.—Dr. C. Herrman presented this case. The child had been born normally of apparently healthy parents. When thirteen months old it had developed measles, and since that time the nodding of the head had been noticed. There was no history of traumatism, and the child lived in a rather dark room, but no artificial light was used. The head moved upward to the left and downward to the right, but there was also some rolling. As Dr. A. Caillé had pointed out, the motions of the head could be checked by covering the eyes. Nystagmus was also present, and could be made more prominent by holding the head. The nystagmus was noticeable when looking to the left, but almost none could be detected when looking to the right. In this case, as in almost all others of the kind, rickets was present. The child was seventeen and one-half months old, but did not even stand yet, and there were abundant evidences of rickets. The hygienic treatment was most important. He had tried the bromides in a number of these cases with practically negative results. These children were apt to hold the head to one side, and then roll or turn the eyes in an opposite direction. The prognosis was good.

Dr. Louis Fischer said that many authors, among others Baginsky, had recently referred to the apparent uselessness of phosphorus in the treatment of rachitis. The speaker said that the more he used phosphorus in these cases, the more impressed was he with the truth of this teaching. Chemists said the so-called phosphorized oil contained no phosphorus.

Dr. Dessau said that he had used phosphorus very largely for many years, but had used it in conjunction with cod-liver oil. The phosphorus was administered in the form of the U. S. P. elixir of phosphorus. As he never gave the phosphorus without the cod-liver oil, it was impossible to say whether the marked improvement observed under such treatment was attributable only to the oil or was, in part at least, due to the phosphorus. He was, however, a firm believer in the efficacy of phosphorus as a remedy in rachitis.

Dr. H. S. Stokes said that none of the five or six cases of spasmus nutans that he had seen were rachitic, though undoubtedly the child just presented was so. They had usually presented a distinct history of injury.

The Effect of Heat Upon Cow's Milk as an Infant's Food.—Dr. S. H. Dessau read a paper on this subject. It dealt with the [illegible] of heat on cow's milk. He said that cow's milk as an infant food should be regarded as a raw article of food. When such a milk contained the same elements of nutrition as human milk, their relative proportions were such as to make the two kinds of milk very different articles for infant feeding. The [illegible] of the curd of cow's milk had been recognized from the first as a great obstacle to the use of raw milk for infants. The curd of sterilized cow's milk, as seen in the vomitus, resembled that of human milk, a point that had been very generally overlooked by pediatricians. But the high degree of heat used in the original method of sterilizing milk caused many chemical changes in the milk, among others the decomposition of the fats. He had found that when the temperature of the top-milk was gradually raised by means of the double steam-cooker to 155° or 160° F. for ten minutes, the curd was much softer than usual, and this was still more marked when the milk was mixed with equal parts of water, or in the proportion of one to three. The taste of such milk was not objectionable, as was the case with boiled milk. It was important that the heat should not be raised to the boiling point, and this could be done in practice quite easily by heating the milk in the steam cooker for a period of ten minutes after the water in the outer vessel had begun to boil. This method of preparing milk had the advantage of giving a very digestible article, and at the same time removing most of the noxious germs. By the dilution mentioned the proportion of fats was decreased, but this was apparently offset by the increased digestibility. These conclusions were not founded on theory, but on a large experience and careful practice. There need be no fear of children fed on such milk developing scurvy.

Dr. J. Finley Bell, of Englewood, N. J., said that the heating of cow's milk to 155° F. in a closed vessel would destroy most of the pathogenic germs, though no careful study had been made as yet to show whether or not the anaerobes were destroyed under these conditions. Of course, such heating of milk would not destroy the toxins that might have previously developed in the milk through bacterial action.

Dr. Max Einhorn said that according to his experience boiled milk would coagulate with gastric juice just as quickly as raw milk, and from some experiments that he had made years ago the coagula in the infant's stomach were found to be very large, even after the heating of the milk. The addition of gruels certainly did render a finer coagulum.

Dr. L. Fischer said that according to his experience milk heated to 212° F. gave rise to extreme constipation, also that pasteurized milk would cause a great deal more trouble and constipation than raw milk. Last year he had placed a number of children on milk heated to 145° or 150° F., following out the theory of Russell. It was certain that the milk was much more digestible when given warm, but he would not be willing to risk giving to an infant milk at the temperature of 140° or 145° F., or even at 167° F., unless he knew positively the quality of the milk supplied.

Dr. R. G. Freeman said that the reader of the paper had given the impression that scurvy had been caused originally by sterilized milk, but the collective investigation of the American Pediatric Society showed that it had been very largely produced by the use of patent foods. Unfortunately when scurvy was first investigated it was at the time that sterilized milk was so much in vogue, but a study of a large number of cases showed that sterilized milk was not responsible for more than 16 per cent. of the cases of scurvy. After all, scurvy was rather the result of the use of an unsuitable food than of any particular mode of preparation of the food. He had undertaken some years ago a number of experiments to determine whether pasteurization or sterilization had anything to do with the curds, and he had been unable to satisfy himself that the heating had any effect whatever on the curds. The heating of milk to 140° F. for ten minutes would not kill the pathogenic organisms which we feared in milk; to destroy these, the milk should be heated to at least 160° F. for half an hour.

Dr. Dessau said that he did not make use of sterilized milk except perhaps during the summer, and hence had not observed any special trouble from constipation. Sterilized milk, when first introduced, had been adopted as a daily food, but the appearance of scurvy had frightened many from using sterilized milk on the supposition that this was the cause of the scurvy. At the present time comparatively few physicians advocated the use of sterilized milk as a daily food.

Chemistry of the Stomach Contents in Children.—Dr. Louis Fischer was the author of this paper. He said that he had made a study of this subject, using a Nélaton catheter, No. 6 or 10, to siphon off the gastric contents. This was done with the child on the back, and usully two or three hours after feeding. Many specimens of vomited matter had also been studied. The chemical examination consisted in removing the chyle, filtering it, and testing for hydrochloric acid, lactic acid, propeptone, peptone, and rennet. The condition of the coagulum was also noted. A series of ten breast-fed infants was first examined. Five of these children had a very fine flocculent coagulum in the stomach. Of the other five children, one was syphilitic, one was hydrocephalic, and one was rachitic, and in these a thick coagulum was present from three to four hours after feeding. Hydrochloric acid was present in all but two of these. In all the healthy breast-fed children the curd was very fine. A series of five bottle-fed children was examined. In these infants, the matter vomited two or three hours after feeding was usually thick, lumpy, and acid, and examination showed hydrochloric acid absent, but lactic acid present in abundance. In some cases butyric acid or acetic acid was also present, and there was little or no propeptone or peptone. Hydrochloric acid was absent in the mild as well as in the severe cases of diphtheria examined, but returned during convalescence. In one of his cases of malignant diphtheria, no hydrochloric acid was found in the vomitus until forty-eight hours after the injection of antitoxin. In very young and healthy nurslings there was an excess of lactic acid at the commencement of digestion, while at the completion of this process free hydrochloric acid was found in the same proportion noted in adults. There was a constant antagonism between the lactic and hydrochloric acid.

Dr. Einhorn said that his experiments did not entirely coincide with those presented in the paper. He had examined a series of normal children, both breast-fed and bottle-fed, and in only two had free hydrochloric acid been present. In the stomach of children, gastric juice was secreted in smaller quantity than in adults. The children he had examined had ranged in age from three to eighteen months. Milk contained a large proportion of albuminates which united with the hydrochloric acid as soon as it was excreted. Small quantities of free hydrochloric acid were masked when milk was ingested, and that was the reason why a test meal of roll and tea, or of some material containing comparatively little albuminate, was selected for such examinations. It was generally believed that in febrile affections there was an absence of hydrochloric acid, but while this was the general rule, he had found some adults suffering from typhoid, and having considerable fever, in whom hydrochloric acid was present. The diminution of gastric secretion and its return during convalescence in cases of diphtheria did not seem to him to be of prognostic value, except as an indication of a restoration of one of the bodily functions, and hence a general improvement. He thought massage of the stomach was not altogether free from risk.

Dr. M. I. Knapp spoke of the technique employed in testing the gastric secretions. He said that he had made a number of experiments for the detection of acetic, butyric, citric, formic, lactic, malic, succinic, oxalic, and tartaric acids, and they had all reacted more or less with Congo paper, and also with methyl orange. Ginsberg's reagent he had found excellent. The ammonio-citrate of iron with potassium ferrocyanide formed a blue compound only in the presence of an inorganic acid. He had known this to give a reaction when the Ginsberg reagent had failed. He had found no benefit from massage of the stomach; in two cases it had caused hemorrhage, and in every instance had given poor results. It tended to lower the acidity. In one of the cases reported in the paper, mention was made of the vomiting of bile, but one should be cautious about asserting that bile had been vomited simply from the appearance of the matter ejected.

Dr. Fischer, in closing, said that the cases of diphtheria in which the gastric secretion had been checked had not been associated with any noticeable degree of fever. Although the treatment of stomach disorders by massage had been unfavorably criticised this evening, he looked upon it as a most important therapeutic measure, particularly in cases of infantile constipation. He had used it in hundreds of children, and was sure that it promoted peristalsis and secretion. Naturally, he did not leave this procedure to the mother, but had it done by a competent massage operator. Two drugs had served him well in these cases—nux vomica and dilute hydrochloric acid. The latter had been particularly valuable. The paper just presented was merely a preliminary communication.

Therapeutic Hints.

Chordee.—

℞	Camphoræ	gr. xx.
	Pulv. opii	gr. v.

Eggs in Therapeutics.—A mustard plaster made with the white of an egg will not leave a blister

The white skin that lines the shell of an egg is a useful application for a boil

White of an egg beaten with loaf sugar and lemon relieves hoarseness—a teaspoonful taken once every hour

An egg added to the morning cup of coffee makes a good tonic

A raw egg with the yolk unbroken taken in a glass of wine is beneficial for convalescents

It is said that a raw egg swallowed at once when a fishbone is caught in the throat beyond the reach of the finger will dislodge the bone and carry it down

The white of a raw egg turned over a burn or scald is most soothing In bowel trouble a partly beaten raw egg relieves the feeling of distress—*The Public Health Journal*

Dysphagia.—Yonge strongly recommends orthoform for the treatment of the distressing dysphagia which accompanies laryngeal tuberculosis It is non-toxic anæsthetic and antiseptic

Watson Williams considers a large majority of cases of acute follicular tonsillitis of rheumatic origin This perhaps explains why ammoniated tincture of gum guaiac given internally is so promptly effective in these cases

Schamberg considers arsenic and mercury the drugs which exert the best influence in lichen planus

In lumbago, dry cupping is often a most ready and valuable therapeutic measure—*Journal of Medicine and Science* July, 1901

Recovery from a Temperature of 110° F.—James Cantlie reports a case in the practice of Dr Wm Hartigan in Hong-Kong A man over fifty years of age, engaged in superintending harbor works developed a high temperature about 10 o'clock in the morning The temperature quickly rose and when Dr Hartigan saw his patient the thermometer registered 110° F On testing the thermometer it was found to be perfectly reliable When the writer saw the case some forty minutes later, the temperature was 108.2° F, although the patient was and had been perspiring freely and although his body was wrapped in wet sheets and was being rubbed with ice The patient seemed by his appearance to be beyond recovery when the temperature was at its highest, but yielding to treatment energetically pursued the temperature rapidly fell and in two hours after attaining its maximum dropped to 102° The patient recovered completely, and in a week or so was about again—*The Journal of Tropical Medicine*

New Instruments.

A NEW ŒSOPHAGOSCOPE.*

By MAX EINHORN, M.D.,
NEW YORK.
PROFESSOR OF MEDICINE AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

Œsophagoscopy in the diseases of the œsophagus and cardia has gained an important place in the last few years. All the literature of importance on this subject will be found in an article[1] published by me in the year 1897 regarding the inspection of the œsophagus and cardia. Later, some important papers on œsophagoscopy appeared by von Hacker[2] and Rosenheim.[3] Von Hacker's epoch-making labors show plainest the high and practical value of this method of examination, which not only facilitates the diagnosis of many of the diseases of the œsophagus, but frequently exerts a direct influence upon their treatment.

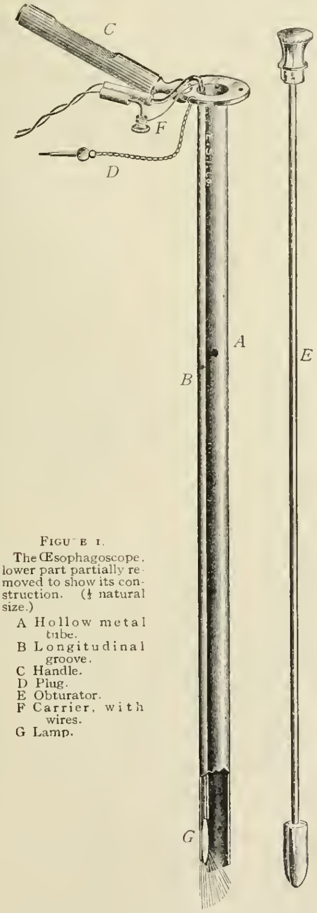

FIGURE 1.
The Œsophagoscope, lower part partially removed to show its construction. (⅓ natural size.)
A Hollow metal tube.
B Longitudinal groove.
C Handle.
D Plug.
E Obturator.
F Carrier, with wires.
G Lamp.

In the instruments used up to now for œsophagoscopy (Mikulicz, Rosenheim, Kelling) the source of the illumination is outside of the œsophageal tube. As a rule, the panelectroscope is employed for this purpose—an instrument that throws concentrated light through the whole tube, thus illuminating the lowest spot that is to be inspected. It is evident that inspection would be easier if the lamp were placed at the lower end of the tube near the area to be examined, since a better illumination could in this way be secured.

Formerly, the construction of such an apparatus could not be accomplished, as after a while much heat was involved by the electric lamps, thus threatening burning of the tissues. More recently the Electro-Surgical Instrument Company of Rochester, N. Y., has succeeded in manufacturing so-called cold electric lamps. They generate very little heat indeed, and can be held from one to two minutes, and even longer, between the fingers or in the mouth, without interruption of current and without generating any considerable heat.*

Since a short time the above principle and these lamps have been used for urethroscopy and proctoscopy. I have constructed a similar instrument for the œsophagus.

The œsophagoscope, constructed for me by the firm mentioned above, consists, as the accompanying drawing (Fig. 1) will illustrate, of a round, hollow metal tube (A), having on one side a small longitudinal groove (B), which is separated by a thin wall from the lumen of the tube. Two isolated electric wires attached to a carrier (F†) run through the groove (B). At their end a small lamp (G) is attached and placed a little above the end opening of tube (A), being, however, not inclosed by the thin metal sheet that covers the wires. To the tube is attached a handle (C), a plug (D), and an obturator (E). Before introducing the instrument the obturator must be in place, and is held there firmly by means of the plug (D). After the introduction of the instrument, this plug is removed and the obturator withdrawn. The wires are connected with an electric battery, and everything is now ready for inspection. The handle (C) facilitates the use of the instrument.

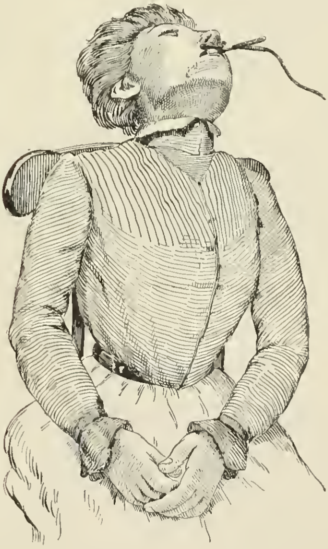

FIG. 2.
Showing patient with œsophagoscope inserted ready for inspection.

---

*Read before the Medical Association of Greater New York, with demonstrations, December 9, 1901.

*I am now using these lamps of 6 to 8 candle-power for my gastrodiaphane.

†The carrier can be easily removed with the lamp, thus facilitating thorough cleansing and sterilization of the instrument and any necessary renewal of lamp.

As already mentioned in my former paper, I usually practise œsophagoscopy in the sitting posture without any anæsthetic (cocaine spray, etc.). The procedure is not a difficult one, and is done as follows:

Method.—The patient sits on a chair which has a back. The instrument (with obturator inserted) is first dipped in warm water and, while depressing the tongue with the left index finger, is held in the right hand like a pen and introduced into the mouth and pharynx of the patient. The latter is now directed to throw his head backward and the instrument is then passed down into the œsophagus without exerting pressure.

The accompanying drawing (Fig. 2) shows the position of the patient after the introduction of the instrument. Attention must be paid that the lips of the patient are not pressed by the instrument. The obturator is now removed, the connection made, and inspection may then take place by looking into the tube. At the end of this, the mucous membrane of the œsophagus is plainly visible. If the instrument is slowly withdrawn while looking into it, the whole wall of the œsophagus may thus be inspected.

I have had the œsophagoscope made in two different lengths (35 and 40 cm.) and thicknesses (1 and 1¼ cm.), which will fulfill various indications. The thicker instrument will be used more especially in the local application of medicaments, or for the removal of foreign bodies, whereas we would ordinarily get along with the more slender instrument.

The new œsophagoscope* has proved to be of great value and I do not hesitate to recommend it warmly.

Contagious Diseases Weekly Statement. Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending January 18, 1902:

	Cases	Deaths
Measles	689	25
Diphtheria and croup	314	52
Scarlet fever	270	23
Smallpox	18	5
Chickenpox	85	1
Tuberculosis	257	147
Typhoid fever	38	11
Cerebro-spinal meningitis	..	3

Results of Scientific Balloon Ascensions. Some results of the scientific balloon ascensions made in Europe under the direction of the International Aeronautical Committee are as follows: Great variations have been found at different localities, even in the uppermost layers of the atmosphere.

The coldest regions lie to the northeast, the warmest to the southwest, of the European Continent. At an altitude of 5,000 meters the temperature was 20° C. above Paris and only 110° C. above Vienna at the same time. The isothermal lines at 5,000 meters run from south toward northeast. Thus, the isotherm 14° C. extends first from the north of the Adriatic Sea to Moscow; that of minus 15° from southwestern France to St. Petersburg, etc. The isobars of 5,000 meters also extend in general in the same direction. The lowest pressures are above England, the highest above southeastern Europe. The velocity of the wind increases from 8.3 meters per second at 1,000 meters altitude to 11.0 meters at 5,000. At altitudes above 6,000 meters the velocities are probably above 16 meters.—New York Sun.

Erysipeloid. Lassel reports nine cases of this disease, which is also known as erysipelas or erythema serpens. It occurs chiefly in persons who are brought into close contact with animals, especially dead or slaughtered, also those engaged in the tanning industry. In the majority of cases the incubation period is from one to three days. The symptoms are at first not directly localized at the seat of infection, but the redness and inflammation at once involve the neighboring regions. In contrast with what occurs in streptococcus and staphylococcus infections, no suppuration is usually produced. The deeper tissues are at first involved, the cutaneous being subsequently affected. The cutaneous appearances are not marked by a sharp demarcation between the involved and sound portions, as is seen in erysipelas. No lymphangitis or lymphadenitis is usually present. Temperature elevations are occasionally observed, but the pulse is not increased over the normal and is sometimes reduced in frequency. Respiration is not affected. The duration of the disease is usually about ten days. Rarely is it completed in two or three days, and in some cases three weeks are required. The differential diagnosis is not, as a rule, difficult. The principal diseases with which erysipeloid may be confounded are erysipelas, erythema multiforme, streptococcus and staphylococcus infections and glanders. The specific bacterial excitement of the disease is unknown. The local application of unguentum cinereum and ichthyol is followed by good results. Internal medication is rarely required, but when indicated it should be symptomatic in nature.—*Deutsche Zeitschrift für Chirurgie.*

Tetanus After Subcutaneous Gelatin Injections.—Hans Lorenz adds two more cases to the rapidly increasing list in which tetanus has followed subcutaneous inoculations of gelatin. In the first case, the injections were employed for the relief of hæmaturia, and in the second, for that of a severe prolonged secondary hemorrhage following operation for carcinoma of the rectum. Both resulted fatally. The source of infection was not ascertained. At the time of the inoculations ample antiseptic precautions were taken. A portion of the gelatin solution which was used in the second case was subsequently inoculated subcutaneously, intravenously, and intraperitoneally into animals without result.—*Deutsche Zeitschrift für Chirurgie.*

The Report of the British Departmental Committee on Food Preservatives.—This report has recently been published and naturally contains much matter of great interest to those concerned in the pure food question. It would appear that preservatives are used almost as largely in Great Britain as in this country. Manufacturers and producers of food of all kinds will, if the recommendations of the British Committee are followed, be bound by strict laws to use no more of food preservatives than is necessary, and not incompatible with health.

Insanity in the Country Districts of England. The *Medical Press* has recently referred to the fact that insanity appears to be greatly on the increase in the rural parts of Great Britain, and that some country parishes are perfect hotbeds for the propagation of insanity. Intermarriage is said to be the cause.

CARBONATE OF CREOSOTE IN PNEUMONIA.

By W. H. THOMSON, M.D., LL.D.,
NEW YORK
PHYSICIAN TO THE ROOSEVELT HOSPITAL.

In the Medical Record of November 2, 1901, Dr. Leonard Weber reports nine cases of pneumonia treated by creosotal, or the carbonate of creosote, with one death. As I had already formed a favorable opinion of the same remedy in the treatment of this disease in private practice and in consultation, I determined to put every case admitted with lobar pneumonia to my wards in the Roosevelt Hospital, as far as possible, exclusively upon this drug, so far as medication was concerned. Eighteen patients were so treated from May 1 to November 1, 1901, six of them during the months of July and August being under the care of my colleague, Dr. Frank W. Jackson, who consented to continue this treatment with them. Of these patients, fifteen were males and three females; two under the care of Dr. Jackson were boys, ten years old, while the ages of the others ranged from thirteen to forty-five. Two (males) were colored. Of these eighteen patients, one (male) died, and the rest recovered, a record which, so far as it goes, is much more favorable than my usual experience in pneumonia, whether in hospital practice or outside. Both lungs were involved in three patients, all of whom recovered, while the remainder, six, had the right lung attacked, and nine the left.

As will be seen from the reports which have been condensed from the hospital books by my house physician, Dr. A. W. Bingham, the patients presented a fair average of the ordinary symptoms and conditions in lobar pneumonia, so that they could hardly be called selected cases. Whether they generally ran a milder course owing to seasonal conditions cannot be decided, but at least in three very alcoholic patients, one of whom had double pneumonia, the conditions were severe enough to be worthy of special mention. The first of these, Case III, the man, aged thirty-three, had long been a heavy drinker, and for six weeks previously had severe bronchitis. He was then attacked with chills, vomiting, great pain in the præcordia, rusty sputum, and marked prostration. On admission on the third day, though his temperature was only 102°, his general condition looked very unfavorable, his lips were cyanosed, and his tongue heavily coated and dry. His temperature then rose steadily, and by the eighth day reached 106°. His temperature did not reach normal till the twenty-first day.

The second, Case XV, that of a large, powerfully built man, aged forty-five, was admitted as a private patient to the Roosevelt Pavilion, with the following antecedents: He had long indulged freely in liquor, and his attending physician stated that for at least six months he had albumin in his urine, and was often languid and stupid. For the past three months he was very restless nights. Six weeks ago, he had a spasm which lasted but a short time, and during which he did not lose consciousness. The excitement of the election campaign, in which he was greatly interested, led him to excessive drinking, till at 10 o'clock A.M., October 10, he was seized with a violent epileptic convulsion, in which he severely bit his tongue. He did not fully recover consciousness till 2 P.M., when shortly afterward he had another convulsion, and then he remained in coma with recurring convulsions till 10 P.M., when he was admitted to the hospital, and I was summoned to see him. After my arrival, he had two more convulsions in quick succession. His pulse was 124, and of very high tension. He had passed no urine since 10 A.M., and only 6 ounces were obtained when he was catheterized. It was pale, sp. gr. 1010, albuminous, and with abundant fatty and granular casts. I ordered him to be bled 12 ounces, with dry cups over the kidneys, and had ½ drachm sodium bromide and 20 grains of chloral given per rectum every three hours, with 10 drops of the tincture of veratrum viride. He had no more convulsions after the bleeding, and the next morning he was conscious, with pulse still of high tension and temperature 100° F., whereupon the veratrum was pushed every half-hour till the pulse became softer. On the third day, he developed the full train of symptoms of delirium tremens, and required incessant restraint. This state continued for two days, when his temperature suddenly rose to 104.4°, and he expectorated a quantity of bright-red blood. On my visit to him that day, I found that pneumonia had fully set in in his right lung, and I was not inclined to give a favorable prognosis, considering the usual course of such cases. The creosotal was given continuously, 15 grains every two hours night and day for ten days, and then at longer intervals, with a gradual descent to normal in three weeks.

The third patient, Case XVI, aged thirty-three, had been a heavy drinker, and stated that he had pleurisy four weeks before admission, from which he had quite recovered, until four days ago, when he had a severe chill, followed by fever, headache, pain in the right chest, cough with scanty sputum, and dyspnœa. Admitted October 21, in a very apathetic state, with flushed cheeks, pulse 120, full and strong, arteries thickened, breathing shallow, and abdomen quite tympanitic. Temperature 104.4°, respirations 40. Examination showed consolidation of the right lung posteriorly up to the axilla, with pneumonic râles over the lower lobe in front. He was ordered creosotal, 15 grains every two hours if awake. The course of his temperature then became very irregular. The next day, the fifth of his disease, it was 100.2° in the morning, and 102° in the evening, but on the next day it was 105.6° in the morning, when pneumonic râles, followed by dulness and bronchial breathing, were found over the lower lobe of the left lung, both posteriorly and anteriorly. The right lung resolved completely by the thirteenth day, but the left not till the twenty-fourth day.

On the other hand, the patient who died (Case V), who was also an alcoholic subject, though he stated that he had been only moderately so, had the creosotal as freely administered as the others, and at first he did not seem to present a specially unfavorable case of the disease. The temperature, however, continued persistently high and was quite unaffected by the medication, reaching before death 107°.

The remedy also can hardly be credited with the favorable result in Case IV, as the man was admitted on the sixth day of the disease with a temperature of 104°, which was followed in about twelve hours with a crisis dropping it nearly to normal.

That the drug may exert a special effect upon the course of pneumonia is rendered probable by the peculiar course of the temperature after its administration, a fact which I had noted before in other cases, and which is well illustrated in the present list. Thus the disease terminated here by lysis in twelve, and by crisis in only five. In a number of them a fall in the temperature of from one to three degrees occurred within twenty-four hours after beginning with it, but the next day it would rise again, and so continue with a very irregular course for a number of days before it reached normal.

Carbonate of creosote, or creosotal, seems also to affect favorably that very undesirable complication in pneumonia, tympanites, which was pronounced in five of these patients. As I use this drug freely in the treatment of phthisis, I have been struck with its greater toleration by the stomach for prolonged periods than any other agent of this class, such as creosote itself or the guaiacol carbonate. In pneumonia I prefer to give it in 15-grain doses every two hours, night and day, or 180 grains in the twenty-four hours, which is about three times the amount prescribed by Dr. Weber.

I have never noted any depressing effect by it on the circulation when so administered, nor need there be any fear entertained of its acting injuriously upon the kidneys, even if they were previously diseased, as in Case XV. In one patient, a lady with general anasarca, hæmaturia, and abundant tubercle bacilli in the urine, whom I saw in consultation three years ago, creosotal was taken continuously by my advice for nine months, after which the bacilli wholly disappeared from the urine, and she is now in good health. My usual formula for administering it is:

℞ Creosot. carbonat. . . . . ʒiv.
Glycerini . . . . ℥j.
Aq menthæ . . . . ad Oss.
M Dose. Tablespoonful in water.

The following is a brief synopsis of these eighteen cases:

Case I.—Ernest W., aged thirty. Personal history: Non-alcoholic; pneumonia nine years ago, again one year ago. Present illness: Slight cough for one week. No other symptoms until one day ago, then became suddenly weak, and later had severe pain in right side, with shortness of breath. This morning sputum contained blood; no appetite; constipated. Chief complaint: Pain and weakness. Admitted May 13, 1891, on the second day of the disease. Tongue heavily coated and moist; pulse regular and full, and of fair force; breathing rapid and somewhat labored; abdomen distended and tender.

Over right lower lobe, behind and in axillæ, breathing high pitched; voice increased; few subcrepitant râles; slightly sibilant and sonorous breathing over right upper lobe. Temperature 104.4°, pulse 128, respirations 28.

Urine contains heavy trace of albumin and a few granular casts.

W. b. c. 29,200. Treatment: creosotal gr. xv. q. 3 h. if awake. Defervescence by crisis on fourth day. Four days later, comparative dulness over right lower lobe, with bronchovesicular breathing. Five days later, resolution complete. Discharged cured May 26 1891.

Case II.—Katie L., aged twenty-eight. Personal history: Non-alcoholic; grippe five months ago, two months ago dry pleurisy on left side; sick only a few days. Present illness: Three days ago, severe pain in small of back, headache, nausea, chills alternating with fever, no appetite. One day ago cough, mucopurulent sputum streaked with blood. Admitted May 11, 1901. Cheeks flushed, tongue coated and moist, pulse regular and of good force; breathing rapid and difficult. Temperature 105°, pulse 124, respirations 40. Over left lower lobe behind dulness with bronchial voice and breathing; moderate number of subcrepitant râles.

Treatment: Creosotal gr. xv. q. 2 h. if awake. Came in on third day, temperature fell gradually, reaching normal on the ninth day. Signs over the lungs persisting. Three days later resolution complete. Discharged cured May 26, 1901.

Case III.—Already detailed.

Case IV.—George O., aged twenty-six, colored. Personal history: Non-alcoholic, syphilis seven years ago. Present illness: Slight cough for two weeks. Five days ago, chill followed by fever, headache, vomiting, prostration, cough, rusty sputum; pain in epigastrium on right side.

Admitted May 16, 1901. Tongue moist, slightly coated; pulse regular, soft and weak; breathing rapid and shallow; abdomen distended. Temperature 104.4°, pulse 104, respirations 48.

Physical: Over right lower lobe behind, dulness, diminished voice and breathing and a few subcrepitant râles; over left lower lobe behind and in front, many subcrepitant râles coming in on the sixth day.

Treatment: Creosotal gr. xv. q. 2 h. if awake. Temperature fell by crisis on the seventh day. Resolution complete on the fourteenth (14th) day. Discharged cured May 31, 1901.

Case V.—Augustus L., aged thirty-eight. Personal history: Moderately alcoholic. Present illness: Three days ago, severe chill, followed by fever and sweating; pain in left side, cough, and slightly bloody sputum, vomiting and prostration. Chief complaint: Pain in side.

Admitted May 29, 1901. Tongue coated and moist; pulse regular and of fair force, breathing rapid and not labored. Temperature 104.6°, pulse 112, respirations 32.

Over left lower lobe in axillæ, dulness, bronchovesicular breathing, bronchial voice, and subcrepitant râles; few subcrepitant râles behind.

Treatment: Came in on third day, was given creosotal gr. xv. q. 2 h. if awake. Temperature remained high, and patient died on the seventh day; temperature 106°.

Case VI.—William T., aged twenty-six. Personal history: Moderately alcoholic. Present illness: Yesterday morning was suddenly taken with chill, marked prostration, severe pain in left side of chest, vomiting, general body pains. To-day became feverish; cough with blood-stained sputum. Chief complaint: Pain in chest.

Admitted June 24, 1901. Face flushed; tongue moist, heavily coated; pulse regular, small, weak; breathing rapid and irregular because of pain. Temperature 103.2°, pulse 100, respirations 32.

Over left lower lobe posteriorly dulness and distant bronchial breathing and increased voice, few fine râles; slight bronchitis over rest of lungs.

Stimulated vigorously with whiskey, digitalis and strychnine. On June 25 was given creosotal gr. xv. q. 2 h.

Temperature was highest on the fourth day; fell on the fifth to 101.4°, rose to 103.2° in the evening, then fell to normal on the sixth day, then continued between 100° and 102° till the thirteenth day.

At that time px. showed dulness, with diminished voice and breathing over left lower lobe. Patient was discharged cured July 13, 1901.

Case VII.—Hilda S., aged eighteen. Always well. Present illness: Three days ago had chills and fever; severe pain in right side of chest; cough with yellow sputum, shortness of breath, headache, and restlessness. Chief complaint: Pain in right chest.

Admitted June 27, 1901. Cheeks flushed; tongue coated, moist; pulse rapid, regular, good force; breathing rapid, grunting, somewhat difficult. Temperature 104.2°, pulse 120, respirations 48.

Dulness over right upper lobe behind with few subcrepitant râles, patch of dulness over left upper lobe behind.

Came in on fourth day; was given creosotal gr. xv. q. 3 h.; also whiskey and digitalis. Began to defervesce on ninth day by lysis, temperature reaching normal on the eleventh day of disease. On fifteenth day physical examination showed lungs were normal. Was discharged cured, July 13, 1901.

Case VIII.—Leopold K., aged thirty-five. Personal history: Well till present illness. Present illness: Two weeks ago began to feel tired, weak, and had no appetite; ten days ago went to bed; pain in back; feverish next day; cough, with mucopurulent sputum; nausea; vomited. Pain became localized on both sides of the chest; became much prostrated. Chief complaint: Pain in chest. Admitted July 15, 1901. Cheeks flushed, tongue heavily coated, white; pulse regular, full, soft, good force; breathing rapid, shallow; breath foul; abdomen tympanitic. Temperature 105°, pulse 120, respirations 56.

Over right upper lobe, note hyperresonant, dull from third space downward, marked in axilla, less marked over right lower lobe behind; breathing over middle lobe bronchial, over lower lobe diminished; voice bronchial over middle lobe, increased over lower lobe; fine friction sounds over both middle and lower lobes. Over left lower lobe behind marked dulness, with distinct bronchial voice and breathing; a few friction sounds over upper part of lower lobe behind and in axilla.

He came in on ninth day, and on the next day he was given creosotal gr. xv. q. 2 h., with whiskey ℥ss. q. 3 h.

Temperature ran from 102° in the morning to 104.8° in the afternoon till the twelfth day; then fell to 100°, and continued from 100° to 99° till the twenty-second day, when it remained normal. At this time there were still dulness and distant bronchial breathing over the right middle lobe and the left lower lobe. Discharged cured August 8, 1901.

Case IX.—Charles H., aged thirteen. Present illness: Two days ago had severe chill, followed by high fever, increased rapidity of pulse, headache, nausea, vomiting, pain in left side, cough, with white sputum, later streaked with blood; prostration. Chief complaint: Pain in side. Admitted August 2, 1901. Cheeks flushed; tongue dry, heavily coated in center; pulse regular, soft, weak; breathing shallow, slightly labored; sputum rusty. Temperature 103°, pulse 120, respirations 48. Over upper part of left lower lobe behind there is marked dulness, with bronchial voice and breathing.

Treatment: Came in on third day; was given creosotal gr. v. q. 2 h.; also whiskey ʒj. q. 3 h.

On the seventh day there was dulness over entire left lower lobe, with bronchial voice and breathing. On the sixth day temperature broke to 99°, then ranged from 101° to 104° till the eighth day, then fell by lysis, reaching normal on the tenth. On the fourteenth day, there was dulness over left lower lobe, with diminished breathing and voice to base. Discharged, cured, August 16, 1901.

Case X.—Robert F., aged twenty-six (colored). Good health till present illness. Present illness: For two weeks has had nausea and attacks of vomiting; remained at work; five days ago had a chill, followed by vomiting, fever, pain in side, cough, scanty, white sputum. Chief complaint: Cough, pain in side.

Admitted August 7, 1901. Tongue heavily coated, brown, rather dry; pulse regular, soft, fair force. Temperature 105°, pulse 116, respirations 42.

Px.—Over left lower lobe behind and in axilla marked dulness, slightly diminished fremitus, bronchial voice and breathing, few friction sounds.

Treatment: Came in on fifth day; was given creosotal gr. v. q. 3 h.

Temperature fell on the ninth day by lysis, reaching normal on the tenth day, and remained down. On the eleventh day, there was marked dulness, and bronchial voice and breathing over left lower lobe, with many subcrepitant râles. Discharged cured, August 16, 1901.

Case XI.—James F., aged ten. Past history: Pleurisy and pneumonia for two weeks one year ago; subject to attacks of croup; has been well lately. Present illness: Four days ago, after having been in bathing, woke up with fever; severe pain in side and abdomen; headache; vomited twice; became somewhat delirious; had cough with scant sputum. Chief complaint: Pain in left side.

Admitted August 11, 1901. Face flushed, herpes on upper lip and left cheek; tongue moist, coated; pulse regular, good force; breathing shallow, labored; abdomen somewhat rigid and tender. Temperature 103°, pulse 122, respirations 36.

Px.—Expansion diminished over left lung, marked dulness over left lower lobe behind, bronchial voice and breathing over upper part of left lower lobe; many fine pleuritic râles over entire left lower lobe behind.

Treatment: Came in on fifth day, with temperature 103.4°; was given creosotal ♏iij. q. 3 h. if awake Temperature fell by crisis on seventh day; on August 11, resolution was complete, and he was discharged cured.

Case XII.—Edward H., aged ten. Past history: Good. Present illness: Four days ago began to have headache; vomited once; felt feverish; had pain in back; no appetite; dry cough; pain in right side, made worse by coughing. Since then fever has increased; cough has been worse; vomited at intervals; has had diarrhœa; continued to get weaker and felt prostrated. Chief complaint: Cough; pain in side.

Admitted August 18, 1901. Tongue moist, coated; pulse regular, good force; breathing rapid, shallow. Temperature 104°, pulse 134, respirations 48.

Dulness with bronchial voice and breathing over upper lobe of right lung; dulness extends to third space in front; many subcrepitant râles, apparently pleuritic.

Treatment: Came in on fourth day of disease, with temperature 104.4°. Creosotal, gr. iij. q. 3 h., if awake, was begun next day. Temperature began to fall on the afternoon of the sixth day, and reached normal in the morning of the seventh day of disease. Temperature remained normal, and he was discharged cured, August 26, 1901.

Case XIII.—Ellen L., aged thirty-six. Past history: Good. Present illness: Six days ago began to have severe pain in left side, made worse by breathing; had headache, pain in back and legs; felt chilly. Next day felt prostrated and vomited food;

was very feverish, slight cough without sputum. Yesterday and today pain is better and feels more comfortable. Chief complaint: Weakness, fever.

Admitted September 7, 1901. Cheeks flushed, tongue moist, coated, pulse regular, fair force, abdomen somewhat distended. Temperature 103.8°, pulse 108, respirations 36.

In left axilla from third rib to base, slight dulness and bronchial breathing. Bronchial breathing over left interscapular region.

Treatment: Came in on seventh day of disease with temperature 103.8°. Given creosotal gr. x. q. 3 h. if awake. Temperature ran from 103° to 100° on the eighth day, 101.4° to 103.8° on the ninth day, 99° to 101.2° on the tenth day, 98° to 99.8° on the eleventh day, then remained normal. Discharged cured September 23, 1901.

Case XIV.—Fred H., aged twenty-five. Past history: Pneumonia seven years ago, sick about four weeks. Present illness: Two weeks ago began to cough, mucopurulent sputum, headache and had no appetite. One day ago began to have severe pain in left chest, made worse by coughing and breathing, felt chilly during day and then feverish, sputum became rusty. Chief complaint: Pain in left chest.

Admitted September 12, 1901. Tongue moist, considerably coated, white, pulse regular, soft, fair force, breathing shallow. Temperature 105.6°, pulse 120, respirations 32.

Over left lower lobe from just above angle of scapula to base marked dulness with bronchial voice and breathing; these do not extend to axilla, an occasional subcrepitant râle over both lungs.

Treatment: Came in on second day, with temperature 105.6°. On the third day temperature was 102° in morning, 105.4° in afternoon, on the fourth day 101.8° to 102.8°, on the fifth day 100° in morning, 98.4° in afternoon. For next four days it varied from normal to 100°, then remained normal. On the tenth day there was slight dulness over left lower lobe, diminished breathing, and a few fine subcrepitant râles. Was discharged cured August 25, 1901.

Case XV.—Already detailed.

Case XVI.—Detailed above.

Case XVII.—Tony L., aged thirty-seven. Past history: Good. Present illness: Four days ago had a chill, followed by fever, pain in head and in right side, cough with no sputum, appetite poor, bowels regular. Chief complaint: Cough.

Admitted October 30, 1901. Cheeks flushed; tongue moist, coated, pulse regular, soft, fair force. Temperature 104°, pulse 96, respirations 24.

Over right upper lobe in front dulness in first, second, and third spaces, and in upper part of axilla behind over upper part of lower lobe, area of dulness, bronchial voice and breathing; a few crepitant râles; fremitus increased.

Treatment and course: Came in on fifth day with temperature 104°; on sixth day, 102.6° in morning, 104° in evening, seventh day, 104° in morning, 103.2° in evening; eighth day, 102.8° in morning, 100.4° in evening, ninth day, 98.2° in morning, 99° in evening, then remained normal. On day of admission was given creosotal gr. xv. q. 3 h. if awake. On nineteenth day, signs were persisting to a slight degree; otherwise is perfectly well November 13, 1901.

Case XVIII.—Annie S., aged thirty-five. Past history: Good. Present illness: Four days ago had a chill, felt feverish, had headache, no vomiting, lost appetite, pain in right side, especially marked on deep inspiration; moderate cough, but no expectoration, chill not repeated; pain in side severe; considerably prostrated. Chief complaint: Cough, pain in side.

Admitted October 30, 1901. Face flushed, looks prostrated, tongue moist, heavily coated white, pulse rapid, regular, soft, good force, breathing shallow, slightly labored. Temperature 104.6°, pulse 124, respirations 44.

Diminished expansion on right side. Over right lower lobe behind dulness from half way between spine and angle of scapula, flatness from there to base, also in axilla and in front below fourth rib, fremitus diminished, breathing absent over flatness in front, in axilla, and over extreme base behind, voice diminished over area of dulness and flatness, few crepitant râles in front and in axilla, over flatness also behind.

Treatment and course: Came in on fourth day with temperature 104.6°. Was given creosotal gr. xv. q. 3 h. if awake. Fifth day, temperature 101.4° in morning, 104.2° evening; sixth day, temperature 102° in morning, 103.6° evening; seventh day, temperature 103.4° in morning, 105.4° evening. Temperature fell by crisis in afternoon of seventh day, reaching 99° on morning of eighth day and remained down. Resolution complete on eighteenth day and patient is now, November 13, 1901, up and nearly well.

RINGWORM: A NOTE ON ITS TREATMENT.*

By GEORGE THOMAS JACKSON, M.D.,
NEW YORK.

CHIEF OF CLINIC AND INSTRUCTOR IN DERMATOLOGY, MEDICAL DEPARTMENT OF COLUMBIA UNIVERSITY.

Ringworm, like the poor, we have always with us. No matter where a doctor's work may lie, whether in the city or in the country, if he is in general practice, he will sooner or later, be called upon to treat ringworm. There are few diseases of the skin easier to cure than ringworm of the so-called non-hairy parts of the body. Sulphur, iodine, salicylic acid, mercury—any one of these in ointment or lotion will cure it. Indeed, most of them are not brought to the doctor, but cured by means of domestic remedies.

While it is easy to cure ringworm of the non-hairy parts, it is difficult to cure ringworm of the scalp and beard, especially the former. In many communities a case of ringworm of the scalp will float around from one doctor to another, and will persist in spite of their best endeavors. No conscientious physician will promise a speedy cure. If the patient is well in six months or a year, the doctor can congratulate himself upon his success.

To a certain extent, this is true of ringworm of the beard, barber's itch. While by no means as intractable as ringworm of the scalp, still six months is often necessary for a cure under most methods of treatment. The reason for the intractability of ringworm of the scalp and beard is that the fungus grows down into the hair follicles, and it is very difficult to make our well-recognized antiparasitics penetrate to the seat of the trouble without damaging the skin.

It is not my intention to detail to you the many methods of treatment with which you are all more or less familiar, but to commend to you one that I have used for some years with excellent effect, and to ask you to give it a trial.

In looking for an excipient that would penetrate easily and be bland, goose grease occurred to me as probably just what I wanted. Many of you have been brought up in the country, and remember how your mother used to rub your nose and throat when you had a cold with goose grease, in the belief that "it would loosen up the phlegm."

I have found it better than I had hoped for. If you will add a drachm or more of the crystals of iodine to the ounce of goose grease, you will have a most effective remedy for ringworm.

---

*Read before the Medical Society of the State of New York.

At the Vanderbilt Clinic, New York City, where we have many cases of ringworm, this preparation has been used extensively for two or three years, almost exclusively after the first few months, when it was found to be more efficacious than other remedies. It is to be applied twice a day until it produces reaction, as shown by a little swelling of the patch. Then once a day will be sufficient. In two or three weeks the hair falls out of the patch, and it becomes bald, like a patch of alopecia areata. After a time, the hair grows again, and the patch is well. The first applications are apt to be a little painful for a few moments, but after that even little children do not complain of pain. No epilation is necessary.

When used on the bearded portions of the face, the applications are more painful than when the scalp is the part treated. If much reaction with swelling is caused, the use of the remedy can be suspended for a few days, and a salicylated oil of 3-per-cent. strength can be used. As soon as the reaction subsides, the remedy should be used again. The result in this form of ringworm is remarkable. A few days ago, I asked Dr. Dade, who has charge of one of the classes for men at the Vanderbilt Clinic, how long it took to cure barber's itch with the preparation. He said just three weeks, as he had noted in a number of cases. This coincides with the results I have had in private practice.

Just one word of caution. Be sure that you obtain the genuine article. I am told by those who should know that the goose grease dispensed by many druggists has never seen a goose, but is manufactured of several fats which, like goose grease, melt at a low temperature. There are some good samples on the market. The finest variety is expensive, as it is made from the fat of uncooked geese.

PROGRESS IN VETERINARY MEDICINE IN ITS RELATION TO PUBLIC HEALTH.*

By DR. WILLIAM HERBERT LOWE,
PATERSON, N. J.

PRESIDENT OF THE VETERINARY MEDICAL ASSOCIATION OF NEW JERSEY.

The progress made in veterinary medicine in its relation to hygiene, as well as in many other respects, during the last few years, has been constant and amazing, and shows that the two great branches of medical science—human and animal—are inseparable. This fact, I believe, is recognized by scientists the world over. The leading veterinary colleges of America are no longer independent institutions, but have become departments of great universities. Cornell and the University of Pennsylvania has each a veterinary department, and the New York University, also, has recently established a veterinary department. This department is the result of the union of the two oldest veterinary colleges in this country, viz., The New York College of Veterinary Surgeons and the American Veterinary College, and the adoption of the consolidated institution as a school of the New York University, under the title of the New York-American Veterinary College.

Comparative anatomy, comparative physiology, comparative pathology, bacteriology, entomology, animal parasites and parasitism, chemistry, physics, meat and milk inspection, and sanitary science are among the subjects found in the curricula of the recognized veterinary schools of to-day.

Harvey's discovery of the action of the heart, and the circulation of the blood, by experiments made upon living animals; Jenner's discovery of vaccination and announcement that smallpox might be prevented by inoculation with the virus of cowpox, are well-known examples of the inestimable value to mankind of a scientific study of animal life in connection with experimentation. In fact, it might be said that it was by the student entering the domain of comparative or veterinary medicine that many of the now known scientific facts were discovered and demonstrated, and as many of the diseases of animals are transmissible to man, the subject assumes an importance of no small proportion when considered from the standpoint of hygiene or public health. Well, indeed, may the New Jersey Sanitary Association give consideration to this subject.

By investigations and experiments, conducted by veterinarians in Texas fever, it was found that cattle in the infective district carried in their blood the contagion of Texas fever; that it was due to a protozoan organism, *Pyrosoma bigeminum*, analogous to the parasite of human malaria, and that this parasite was transferred to susceptible cattle outside the infected district by the southern cattle tick, *Boophilis bovis.* The experiments alluded to are interesting to the scientific investigator and make a remarkable chapter in the progress of medical science. They have already led to extensive studies of the part played by insects in the propagation of human diseases, and particularly malarial and yellow fevers, opening up a new field in medical research, by which it was discovered that mosquitos are responsible for disseminating these diseases.

No fact has drawn a closer relation between animal and human diseases or the protection of the public health through domestic animals than the introduction of the antitoxin principles of serum therapy. The immunizing of animals against fatal contagious diseases; the rapid and certain diagnosis of latent diseases, which cannot be known by physical symptoms, and their early isolation before they have spread their disease germs among their kind, and to the human family; the cure of some diseases by the administration of repeated doses of attenuated virus, and the prevention of development of disease by their early administration, are phases of veterinary science which make it a preserver of the public health. Contemplate for a moment the importance of tuberculin used for the diagnosis of tuberculosis in dairy cattle; mallein used for the diagnosis of latent glanders in the horse; vaccine employed to protect mankind from smallpox; tetanus antitoxin employed in the treatment of lockjaw; diphtheria antitoxin employed in the treatment of diphtheria, as well as other antitoxins employed in the treatment of anthrax, rabies, and other diseases. It is impossible to estimate the value of animal serums to mankind, employed for diagnostic, prophylactic, and therapeutic purposes.

The position taken by Professor Koch in the recent British Congress on Tuberculosis has awakened a great deal of interest in the question of the transmissibility of the tubercle bacillus from animal to man and from man to animal.

The experiments showing the difficulty or the impossibility of transmitting human tuberculosis to cattle in a fatal form cannot be accepted as evidence that the bovine bacillus, which is far more virulent and fatal for many animals, cannot infect man. On the contrary, the greater disease-producing power of the bovine bacillus would appear to make it more dangerous for human beings as well as for lower animals.

---

* A paper read before the New Jersey Sanitary Association at Lakewood, N. J., December 7, 1901.

The evidence showing the practical impossibility of cattle being infected with human tuberculosis under ordinary conditions is a great encouragement for the eradication of bovine tuberculosis, since it proves that the danger so often feared that cattle if freed from the disease would be immediately reinfected from mankind does not exist in fact, and need not be considered.

Even if it were true that bovine tuberculosis is not communicable to man, it would nevertheless be to the interest of cattle and swine growers to have the disease eradicated as an economic measure, and such eradication would also be to the interest of the public, since it would have great effect as a means of preserving the food supply of the nation and of protecting consumers from the unwholesome products of diseased animals.

The communicability of tuberculosis received its full share of attention at the recent annual meeting of the American Veterinary Medical Association held at Atlantic City last September, and resolutions were adopted expressing the sense of the association as above. I might state that a number of veterinarians are making a series of experiments at the present time that promise to be of no little value to science and mankind. Some of these experiments, I am glad to say, are being made in our own State by the Public Health Committee of the Veterinary Medical Association of New Jersey.

The last New Jersey Legislature enacted a pure food law and put the execution of the law under the control of the State Board of Health, and I hope that ample provision is made in said law for necessary veterinary inspection of all food animals as well as animal food products. The qualified veterinarian is the expert on this subject. This association can do much to enlighten the general public on veterinary hygiene and sanitation, and I regard the same as an important function of this organization.

All dairies should be regularly inspected by a competent veterinarian. The cattle should be examined as to their health, and the attendants as to their own healthfulness and cleanliness; the stable should have sufficient air space, be well lighted, ventilated, and drained; the quality and kind of food are important, and the water supply should be uncontaminated. Milk is often tainted, contaminated, or infected after it is drawn from the cow. The whole system of producing, handling, and marketing milk is being revolutionized, and great improvement has already been made in many dairies by enterprising producers.

Milk is pure while in the udder of a healthy cow, but the moment it is exposed, impurities soon deteriorate it. It should be conveyed to the milk house as soon as drawn. Care must be taken that the water in which the milk cans and utensils are washed is not polluted, for it is in this way that epidemics of typhoid fever are sometimes started. No dairyman should give medicine to a cow, and allow the milk to be used, especially for children. The use of various preparations of mercury, arsenic, zinc, iron, iodine, purgatives, and other medicines may easily cause fatal results.

I am of opinion that practitioners of human medicine might, in certain maladies of their patients, especially of children, administer medicine to their patients through the agency of a cow by her milk.

The importance of meat inspection is becoming more evident every day. A layman or butcher is not qualified to do work of this character. It requires the services of the veterinary expert. The danger is not so much from meat of inferior quality or even from putrid meat, as it is from fresh meat containing microorganisms of communicable diseases. Certain parasites (*Cysticercus cellulosæ* and *C. bovis*) are directly transmissible to man through the use of meat. The veterinarian with a knowledge of these worms is able to prevent the spread of their tapeworm stage among human beings by condemning the infected meat or subjecting it to processes which will render it harmless. The rigid system of meat inspection in Germany has resulted in an actual decrease in tapeworm disease (by *Tænia solium*, and probably also by *T. saginata*) in man and in the frequency of *C. cellulosæ* in the human eye.

Condemnation and destruction of organs infested with certain other parasites (*Echinococcus*, *Cœnurus*, *Cysticercus tenuicollis*) will prevent the spread of these parasites in their tapeworm stage to dogs and by that means prevent the reinfection of man (by *Echinococcus*) and of domesticated animals (by *Echinococcus*, *Cœnurus*, *Cysticercus tenuicollis*), in this case, prevention of tapeworm disease in dogs though of comparatively little importance so far as the dogs are concerned, becomes very important not only in public hygiene (in the prevention of disease in man and animals), but also from an economic standpoint, preventing financial loss to stock-raisers from disease and death in their herds and flocks caused by these worms. The destruction of livers heavily infected with flukes will also result indirectly in decreasing fluke disease in man and animals. I would refer those interested to an exhaustive work on the subject compiled by the Bureau of Animal Industry, some of the data of which I have incorporated in this paper.

Pork before being put on the market should be examined microscopically for a minute worm called *trichina spiralis*, which causes the disease known as trichinosis. As a secondary precaution, no pork should be eaten unless it has been thoroughly cooked throughout, so as to kill any parasites which may exist in it. The pernicious and most unsanitary practice of feeding swine with garbage should be prohibited, as it induces disease in that animal whose carcass constitutes a large portion of our food resources.

Cold storage, cooking, or salting will destroy the parasites of certain diseases. In other cases the meat should be "tanked" and converted into fertilizer. In each city and town the slaughtering should all be done at one abattoir, and that abattoir should be constructed upon sanitary principles. There should be a competent veterinary inspector appointed as director in every slaughter-house, with assistants, if necessary.

Veterinary inspection of meat is now being efficiently carried out on a large scale for interstate and foreign trade by the United States Bureau of Animal Industry. Meat inspection should be carried out along the same lines in every city and town in New Jersey. The State, and every city and township, board of health should have at least one veterinarian officially connected with it. Veterinarians should be appointed on boards of health, as well as physicians and others, for no small part of preventive medicine and sanitary science belongs essentially to the veterinary profession.

I take a deep interest in this association because it brings together members of several professions interested in a common cause.

Pathological Society of Philadelphia.—The second annual exhibition meeting of the society was held on January 9, a large number of gross and microscopic specimens being displayed in the Mutter Museum of the College of Physicians of Philadelphia

CASE OF ACUTE ARTICULAR RHEUMATISM WITH PYÆMIC TEMPERATURE, TREATED BY ANTI-STREPTOCOCCIC SERUM.

By R. J. CHIPMAN, M.D.,
PORTLAND, ORE.

Patient, Miss W., aged twenty-five years, was exposed to cold wind and low temperature in Seattle about August 31, and came home from a street-car ride thoroughly chilled. For a week afterward she complained of great nervousness, general malaise, and anorexia. On Saturday, September 8, she had a severe chill, followed by a temperature of 104°, and general muscular pains. The next day, the finger joints of both hands and the wrist joints became painful on motion, with slight swelling, and a few purpuric spots appeared on the arms and legs. She was immediately put on salicylates internally, and externally in the form of salicylic-acid inunctions, and the joints were wrapped in laudanum and soda fomentations. The pain and swelling traveled from one finger to the other from day to day, and finally subsided at the end of the second week, leaving the midphalangeal joint of the left index finger enlarged and stiffened. The temperature ranged from 102° to 104°, the body was bathed in acid sweats, and the patient experienced a chill with a temperature of 104° every three or four days. The salicylates were tried in different forms, and finally discarded entirely, owing to their intolerance by the stomach. Quinine and other antipyretics were tried without effect, and the patient was then treated expectantly with cold sponging to reduce the temperature, and opiates for relief of pain. At the end of the second week the chills became more frequent and the fluctuations in temperature were greater. The left knee became acutely inflamed, and this was followed by swelling of the dorsum of the foot and great toe joint. The leg was put in a plaster cast from the toes to the hip, the knee remaining tense and swollen, and causing acute suffering. The heart sounds during this time were muffled and indistinct, the aortic note being slightly accentuated. There was no increase of cardiac dulness, and no subjective symptoms were complained of. The pulse range was 110-130-146. There was complete anorexia with flatulent distention of the stomach, which gave continual trouble. The spleen was enlarged and tender. The third and fourth weeks were marked by the increasing number of chills, ranging now from one to three in the twenty-four hours, when the temperature would shoot up to 105° and drop in a few hours to 97°; the patient would be drenched in cold sweats, with lips and finger-tips cyanosed. The beginning of the fifth week saw a slight remission of the symptoms for three days, when there were no chills, and the temperature ranged from 97° to 102°; diaphoresis was still excessive. On October 10, after these three days respite, the chills commenced again with increased severity and greater prostration. An axillary temperature was then taken, the patient being unable to hold the thermometer in the mouth; it ranged from 97° to 103.6°. On October 11, at 2 A.M., the temperature was 98.6°; there was a chill, and in three hours (5 o'clock) it was 104°; there was another chill, and the axillary temperature taken for ten minutes three times was 105.4°. At eight o'clock it was 103°, and at 8.30 there was another chill and the temperature rose to 104°. It was decided to try as a last resort the use of anti-streptococcic serum with the hope that it might antagonize the profound septicæmic condition present, which seemed due to some germ infection, possibly by the streptococcus. On that day, October 11, at 2 P.M., the first injection of 10 c.c. was given under the skin of the abdomen, and the temperature did not go above 100° the rest of that day.

At 9 A.M. the next morning the temperature was 100°; a second injection was given, and at 10.30 the temperature was 97° by the mouth; the pulse was 108 (the previous pulse rate had been 110-130). At 12.40 the temperature was 97°, pulse 98; at 2 P.M. it was 97.2°; pulse 108; at 4.30 P.M. the temperature was 98.6°, pulse 120, and at 6.45 P.M. there was another chill lasting a few minutes, and the temperature at 7.25 was 102°. At 9.45 P.M. a third injection of serum was given—the last that could be obtained in the city.

October 13, at 2 A.M., the temperature was 97.4°; there were no more chills that day, and the highest temperature was 102°. The patient felt well, did not perspire any, and complained of pain in the knee only at night; before that it was almost incessant.

October 14, the temperature ranged from 98.6° to 102°.

October 15, the morning temperature was 100.2°. At 1 P.M., more serum having been sent from Spokane and Seattle, a fourth injection was given. The temperature then fell to 99.6°. At 4 P.M. it was 100°; at 6 P.M., 100°; at 8.20 P.M., 99°.

October 16, the temperature was 98.6° to 101°. A fifth injection was given that night at 10.30.

October 17, the temperature at 1 A.M. was 99°, pulse 104; at 7.30 it was 99.2°; at 12.20, 100.4°, pulse 120; at 3.10, 100.2°; at 5.30, 100°; at 9, 100.8°, pulse 120; at 11, a sixth injection was given, and the next morning (October 18) at 8.30 the seventh and last injection was given, the temperature then ranged from 98.8° to 99.2°.

On October 19, the temperature was 98° to 99°; on October 20, it was 98.2° to 100°, and on October 21, it was 98.4° to 99°.

On October 23, a severe attack of urticaria developed, involving the whole surface of the body and causing great distress. This lasted for six days, being worse at night.

At this time, November 7, being two months from the date of the onset, the patient is sitting up, having convalesced very rapidly. The swelling in the left knee has almost entirely subsided, and only slight stiffness remains. The left index finger is still slightly stiff, and enlarged in the mid-phalangeal joint. The heart sounds are normal.

In reviewing the history of this case it seems impossible to ascribe the sudden remission of symptoms to mere coincidence. The patient was greatly prostrated physically and mentally, and seemed to be rapidly progressing toward a lethal ending; all her symptoms were being intensified, when the serum was commenced and the improvement was marked from the first injection, and her condition was practically normal from the third injection. In looking over the small amount of literature at my disposal, I was able to find case reports of serum being used with marked success in erysipelas, cellulitis, and puerperal septicæmia, and of its signal failure in pneumonia. In the *Philadelphia Medical Journal*, October 19, 1901, one observer reports finding in a case of acute articular rheumatism an organism closely resembling the streptococcus, which, on being inoculated into animals, produced a disease presenting the clinical picture of acute articular rheumatism. Autopsy showed marked inflammatory changes in and about the joints, and the latter contained a small amount of turbid fluid. In one of the guinea-pigs inoculated, a well-developed endocarditis was found. It is noteworthy that the patient from whom this organism was originally obtained had a relapse, and the same organism was found the second time. No mention was made of serum therapy in this case, nor am I aware of its having been used in any case of acute rheumatism.

EARLY MECHANICAL EFFECTS OF ALTITUDE OF THE ROCKY MOUNTAIN PLATEAU IN PULMONARY TUBERCULOSIS.

BY J. N. [illegible], M.D.

DENVER, COLO.

Leaving out the ordinary effects of pure, dry, cool air, and sunshine, and also the moral effect of change, in cases of pulmonary tuberculosis with limited involvement of lungs, there is still a most important immediate, and, at first, purely mechanical effect of the altitude of from five to six thousand feet on the Rocky Mountain Plateau. The extensive and [illegible] [illegible] [illegible] as a natural response. In low levels, as a result of the catarrhal condition, there is a more or less constant accumulation in the bronchi, [illegible] [illegible] the mucous membrane [illegible] the bronchioles dilated [illegible] in short, [illegible] the [illegible] stage of pulmonary tuberculosis. The bronchi and bronchioles leading to this diseased area are quickly dilated by the rarefied air, and the deeper respirations necessary to get sufficient oxygen. The quantity of expectoration may, therefore, be at first increased, indeed, a constricted or clogged bronchus may be suddenly dilated and the accumulated contents quickly expelled by expectoration to the alarm of the patient. The unwonted dilatation of the air vesicles and stretching of the trabeculæ may cause the loss of the expectoration in such a paroxysm to be tinged with blood, or there may even be some hemorrhage. The process may fairly be compared to the stretching and revivifying of indolent surfaces, nature's surgery of the lung, a species of curettage previous to the institution of the healing process.

Weber* says that the tubercle bacilli cannot be at once removed by change of surroundings; but the process just described is quite in the direction of accomplishing this. I am convinced that a small cavity even may be emptied by this mechanism. The beneficial effects are plain; quantities of bacilli are removed, the foci for the generation of toxins, for reabsorption of pyæmic material, and the chief source of irritating cough by accumulating mucus are cleaned out. The stagnant and toxin-laden air in the bronchi and vesicles is evacuated, and oxygen admitted.†

The various applications of the pneumatic cabinet have been devised with a view to accomplishing something of this sort, but the great defect is that the application is not sufficiently sustained. It is not simply the relative disease of the breathing area engaged in the morbid process, but the partial clogging of the bronchus leading there, which causes the anæmia and dyspnœa. The dilatation of the bronchus opens to aeration this entire area, and it immediately becomes available for respiration, except, of course, the small spot of ulceration, and this is now fully exposed to the dry aseptic atmosphere. The above considerations, I believe, account for the many phenomenally rapid improvements, and even recoveries, seen in this region, and the reverse of the process explains their often rapid relapse on returning to lower levels. In a denser and more moist atmosphere the lumen of the bronchus diminishes, partly from collapse, partly from tumefaction of the walls, mucopurulent secretion containing bacilli accumulates, toxins form, absorption takes place, and fever returns.

Numbers of persons have related to me the experience of paroxysms of cough, and with large amounts of expectoration, as the first effect of the high altitudes of the Rockies.

GUNSHOT WOUND OF THE STOMACH.

BY GEO. P. JESSUP, M.D.

NEW BRIGHTON, NEW YORK CITY

ATTENDING SURGEON TO THE S. R. S. INFIRMARY

On May 12, 1898, I had just finished making my rounds at the S. R. S. Infirmary, when the police ambulance arrived with a negro who had shot his wife and then himself. He was a burly fellow, of fine physique and thirty years of age. The shooting had occurred about eight in the morning at Tottenville, thirteen miles from the hospital, and he had been transported in a steel tired police patrol wagon and had received no medical attention. He reached the hospital at half past eleven. He was unconscious and nearly pulseless. I had him taken directly to the operating room, and at forty minutes past eleven he was given a small quantity of ether, which anæsthetic was administered with great care and in very small quantities during the operation, which lasted about half an hour. There was a perforating wound, made by a thirty-two caliber bullet, about three inches to the left of the median line and two inches below the free border of the ribs. This wound was surrounded by an areola of swollen and inflamed tissue. I made a five-inch incision in the median line, extending from the tip of the xiphoid process to within two inches of the umbilicus. There presented a slight tear in the right lobe of the liver, and a perforation of the anterior wall of the stomach near the cardiac end. The liver had nearly ceased bleeding, and I made no attempt to suture it. The stomach wound I closed with Lambert sutures of black silk, and cutting through the lesser omentum round the stomach closed the wound of exit, in its posterior wall, in the same manner. After leaving the stomach, the bullet passed through the capsule of the left kidney, and buried itself in the muscles of the back. It was removed four weeks later from just beneath the skin, where it was easily located. There were perforations of the transverse mesocolon, but as these had ceased to bleed, they were left alone. There was still considerable hemorrhage from the kidney, and the abdomen was full of clots and loose blood. The larger clots were removed and part of the blood was sponged out, but no attempt was made to flush the abdomen or remove all the blood. The incision was closed with buried catgut sutures, and the skin with a subcuticular suture. A piece of lamp-wick was put through the bullet wound, just to, but not into, the peritoneal cavity. For twenty-four hours the man was given strychnine subcutaneously every three hours, and rectal infusions of eight ounces of decinormal saline solution at about the body temperature every four hours. At five in the afternoon of the day of the operation, his temperature was 100.4° F., his respirations were 52, and his pulse 108. The next afternoon the temperature reached 101.3°, with a pulse of 96, and from that time continued to go down, never reaching 101° again, and becoming normal on the sixth day. At the end of twenty-four hours after the operation, the man was given peptonized milk. On the fifth day he had "soft" diet, and "home" diet on the tenth day. He was taken from the hospital to the county jail nineteen days after his injury, and was eventually electrocuted at Sing Sing. I wish to call attention to two factors which seem to me to have influenced the unusually favorable course of this case. First, the incision was not through the wound of entrance, but through sound tissue, and hence healed perfectly under a single dressing, and eight days after the operation was almost imperceptible. The second point is that there was very little handling or disturbance of the abdominal contents. I feel sure that most of us are tempted to disturb the viscera entirely too much in our abdominal work, and that the peritoneum will take care of large blood clots and an almost unlimited amount of free blood or serum, and can even endure the presence of considerable foreign matter, such as the escaped contents of the stomach or intestine. I do not mean in any way to compare this case with that of our late lamented President, for my patient was a young and unusually robust man, an almost ideal subject for such an operation.

GALLSTONES COMPLICATED WITH EMPYEMA OF THE GALL-BLADDER.

By H. T. MILLER, M.D.,
SPRINGFIELD, OHIO.
SURGEON TO THE CITY HOSPITAL.

This patient, Miss H., aged twenty-three years, had been treated for about three years for what was always supposed to be "stomach trouble." When called to attend her in December, 1900, I found her suffering from a large abscess in the region of the parotid gland, and it was at this time that I was given a history of "stomach trouble." I would here interject that I believe that a large number of cases of "stomach trouble" are, in fact, genuine cases of gallstones, and it is only when there is a volcanic outburst of symptoms plainly characteristic of gallstones that a diagnosis of this condition is ever ventured. It is generally supposed that jaundice must be present in every attack, when, in fact, it is rarely, if ever, present, unless the attack should last from three to four days, when one can arrive at a reasonable conclusion that there exists an obstruction in the duct. It happens quite frequently that we discover postmortem calculi in the gall-bladder which in life were never suspected to exist, though there may have been symptoms of stomach trouble always present. In a case in which the attacks are as frequent as two a week, in which the duration of each attack is twenty-four hours, and in which it is necessary to administer frequently a grain of morphine hypodermically, in addition to chloroform, I have never been able to discover, either before, during, or after an attack, the slightest sign of jaundice.

In the case I am about to relate, the symptoms were never those of an acute attack of gallstones, but rather those of a flatulent dyspepsia. I was called one night in January last and found the woman suffering with symptoms so plainly characteristic of gallstones that a diagnosis was easily made. Though there had been more or less constant disturbance of the stomach, and moments when there would be freedom from all suffering, yet there were never present any symptoms resembling those of an acute attack of gallstone colic. Frequently she would seat herself at the table, feeling that she could eat heartily, and after eating a few mouthfuls be compelled to leave the table and not get any relief until the stomach had been thoroughly emptied of its contents. Not until the night that I was called had any of the attacks been so pronounced as to prompt a diagnosis of gallstones. In this attack, I found her lying upon the floor in the throes of the most agonizing pain, and giving vent to the most pitiful and piercing shrieks; and it was not until I had given heroic doses of morphine that I was able to make a satisfactory examination. I could then define a globular tumor swaying to and fro in the abdominal cavity, like the pendulum of a clock, as the patient turned from side to side. The tumor was so low in the abdominal cavity—on a level with the umbilicus—and the movement was so free, that I hesitated in diagnosis between gallstones and right floating kidney. The sudden ushering in of the symptoms, however, with a distinct chill, rise of temperature followed by a sweat, and the presence of jaundice, prompted the diagnosis of gallstones complicated with empyema of the gall-bladder, and I advised an immediate operation.

The following morning the patient was taken to the hospital and the abdomen opened, revealing the gall-bladder, greatly distended, protruding about three inches below the border of the liver. After the gall-bladder had been isolated from the peritoneal cavity with sterilized gauze, it was opened and gave exit to at least a quart of pus and nearly two handfuls of stones, varying in size all the way from a millet-seed to a hazelnut. The walls of the bladder were indurated to the thickness of a quarter of an inch.

After the bladder had been thoroughly irrigated, it was closed with interrupted sutures of catgut, the lower end being left open for the drainage tube. In closing the external incision, two sutures were passed through the walls of the bladder, one above and one below the tube. At the end of four days, the tube was removed, leaving a fistula which in about ten days closed entirely, the patient being discharged from the hospital about a week later.

It is now nearly a year since the operation, and aside from an occasional pain in the region of the liver, there has been no return of the gallstones; in the meantime, however, the patient has been taking ten drops of the tincture of carduus marianus, three times a day, in alternation with three drops of a solution of the spirits of turpentine in Hoffmann's anodyne (one in twenty) three times a day, being warned to discontinue the drugs should their physiological action become noticeable.

A CASE OF GALACTORRHŒA.

By FREDERIC GRIFFITH, M.D.,
NEW YORK.
SURGEON, BELLEVUE DISPENSARY; FELLOW OF THE NEW YORK ACADEMY OF MEDICINE.

The following case came under my notice at the surgical clinic: F. F., female, aged twenty-three years; married six years; has one child, a boy, five years old. The woman is a blonde, five feet two and one-half inches in height, and weighs 116 pounds, being of good figure and muscular.

While of a bright and cheerful disposition, the woman is of a somewhat nervous temperament; she sleeps restlessly at times, and suffers from headache; the appetite is good; the bowels vary between constipated and loose. Menstruation is always regular, appearing at intervals of twenty-eight days and lasting for five days. It is not painful, the woman stating that rather more pleasure than discomfort is felt at these times. The breasts are of good size and well formed, with prominent nipples and a darkened areola surrounding them.

Without apparent cause, for a period of two years the breasts have exuded a milklike fluid. By manipulation the woman is enabled to project a stream of the milky fluid from both breasts, but the left is rather more active than the right one. Excitement seems to increase the quantity, and the woman considers this abnormal functional activity more in the light of an accomplishment than otherwise. She denies having had a miscarriage since the birth of her child, or any irregularity of menstruation.

Intercourse is carried on at irregular intervals, though the woman is of a passionate nature.

Deciding that frequent manipulations must act as a stimulant to the secreting glands, I ordered the woman to let them absolutely alone, but did not give her any medicine. The case continued without change under my observation for several weeks.

805 Madison Avenue.

CIRCUMCISION FOR THE RELIEF OF ACNE.

By W. C. [illegible], M.D.

[illegible]

Eight months ago a man, twenty-two years of age, applied to me for treatment for an aggravated facial acne of five years' standing. For three years he had been treated by several general practitioners and one dermatologist, but the disease continued to increase in severity. At no time had even temporary improvement been noticeable.

Not long before the consultation, I had read in a medical journal, the name of which I cannot now recall, an article stating that one or two cases of acne had recovered after circumcision. The name of the author has also escaped me.

My patient being an unusually intelligent young man, I explained to him the probable uselessness of attempting to treat him in the orthodox way, because of his inability to accommodate his spare time to mine. I explained the journal article to him and advised a circumcision.

Although his prepuce was not unusually long, and there were no adhesions, he readily consented to the operation, which was done the next day.

I advised him to discontinue all local treatment, internal medication, and special diet. In fact, I told him to eat and drink what he pleased, so as to give the proposed method of cure a perhaps unreasonable test.

Before the wound was completely healed, there was an improvement in his face. At the end of three months the last of the pustules had disappeared. To-day his face is as smooth as any man's, aside from numerous scars following the incision of pustules several years ago.

I see no reason why one would not be justified in freeing adhesions, if present, between prepuce and clitoris of girls and young women, who so often have acne, particularly in those stubborn cases which resist the usual methods of treatment. I had hoped to have such a case to report with this one, but have been unable to secure the consent of the patient to the procedure.

PROTOZOA IN GANGRENOUS STOMATITIS.

By W. MOSER, M.D.,

BROOKLYN, N. Y.

PHYSICIAN TO THE GERMAN HOSPITAL.

It is possible that in gangrenous stomatitis (cancrum oris, noma) we may not be dealing with the same etiological factor at all times. That mercury may produce a severe stomatitis is well known.

Aside from the ordinary aphthous stomatitis in childhood, which usually improves with borax washings or nitrate of silver applications (gr. 1 to ℥ j), there occurs a severe form of stomatitis with gangrenous ulcerated cheek and disease of the bone, ultimately leading to death through septic venous thrombosis or general septicæmia. Now and then, however, a child severely affected, after a protracted illness ultimately recovers.

A few years ago (1897), while making microscopical examinations of the exudation of a severe gangrenous stomatitis, I encountered protozoa. The microorganism was ovoid in shape and remarkably lively in its movements. It was slightly larger in size than the average red blood cell. If it possessed cilia or flagella, I did not detect them. I have seen these organisms in three cases, and believe they stand in causal relation to the disease. It is possible, however, that they may have been only incidental, although protozoa are not usually found in the normal oral cavity.

It is well known that the mouth is a favorite habitat of microorganisms, and notably of fungi, such as leptothrix, streptothrix, mycothrix, and other thread-like species. The ray fungus (actinomyces) is apt to gain entrance through some decayed tooth and produce the well known symptoms of "lump jaw." Few of the fungi found in the mouth have yet been artificially cultivated. Miller, however, who has described many forms of fungi and cocci in the mouth, has, in conjunction with other investigators, produced cultures of the Iodococcus magnus and parvus. The Leptothrix gigantea of Miller, an unusually large fungus, probably stands in causal relation with pyorrhœa alveolaris in which disease it has been found.

Without entering into a study of the morphology and biology of the many described forms, we may note that it is easy to demonstrate fungi in most cases of aphthous stomatitis and in mercurial stomatitis. In both conditions they are more abundant than in the healthy mouth.

The Spirochæte dentium is an organism having much resemblance to the spirillum of Obermeier. Both have pointed ends, and are regarded by Koch as quite distinctive from other forms of spirilla. I regret to be unable to give a more minute or accurate description of the protozoon seen, or to name it properly, but hope that some investigator who has studied all varieties of protozoa may yet do this.

I would suggest in the treatment of gangrenous stomatitis an application of pure carbolic acid followed immediately by alcohol, as is done in the case of infected abscess cavities.

Ichthyol in Tuberculosis.—Charles P. Spangler considers it doubtful if any climate can be so perfect that it will not bear some additional means of enhancing its efficiency. This he finds in ichthyol, which possesses a wide range of therapeutic utility by reason of the innocuous form of sulphur contained in its composition. It is acceptable to the stomach, promoting its function, is readily absorbed by the alimentary mucosæ, and when administered in quantity is in turn eliminated by the mucous surfaces in general. In the tissues it possesses to a high degree the property of stimulating that function of protoplasmic life concerned in constructive metabolism, resulting in an increase in bodily weight, and aside from the local impression exerted through the process of elimination, accomplishes its chief curative value in tubercular and other forms of wasting disease through this reconstructive property. The chief objections to its use are the odor, taste, and eructations which are neutralized to a considerable extent by the use of capsules. Ichthyol is especially valuable in the treatment of patients who are unable to seek an appropriate climate.—*Proceedings of the Philadelphia County Medical Society.*

The Koplik Spots in Measles.—Emil Feer says that the presence of the so-called "Koplik spots" in the pre-eruptive stage of measles is almost universal and is of great diagnostic importance. These spots vary greatly in size, but the original description of them given by Koplik is amply sufficient for their determination. The time of their appearance is somewhat variable. The author observed seventy-five cases, in sixteen of which they were first noticed one day previous to the eruption; in nine cases, two days previous, in four cases, three days previous; and in one case, four days previous. In thirty cases they were not present until the first day of the eruption, and in seven cases not until the second day. So far as Feer's observations extend, these spots are not found in other diseases. Especially is this the case in German measles. Here their absence or presence is a valuable differential diagnostic sign. They are also of great prophylactic value, as by their means cases may be isolated before the eruptive stage, and the other members of the family protected. —*Correspondenz-Blatt fur Schweizer Aerzte.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, February 1, 1902.

THE AMENDED CHARITIES BILL.

THE charities of New York State, and of New York City in particular, are a magnificent and enduring testimony to the generosity and public spirit of the inhabitants. Money is poured forth with a lavish hand to assist the sick and needy, and although the charge has been of late frequently made that undue extravagance has characterized the management of charitable institutions under the existing system, the majority of those versed in such matters believe that, upon the whole, the methods now employed are best suited to the circumstances.

Governor Odell's plan, as sketched in his message, to centralize the management and patronage of the eleven State insane hospitals and to invest their control in a State Commission in Lunacy at Albany has met with stout and determined opposition. The criticism of the opponents of the measure to abolish the boards of managers has had the effect of deciding the Assembly Judiciary Committee to amend the bill, so that some of the opposition may be allayed, but the patronage of the State hospitals will still revert to the State Commission in Lunacy.

The bill in its amended form does away with the local boards of managers, substituting for them a visiting board of five members for each State hospital. The visitors must live within the hospital district to which they are appointed.

These changes would seem to be in the nature of a "sop to Cerberus," and leave the situation, to all intents and purposes, *in statu quo*.

In the first instance, it is cogently argued that a visiting board of five members could not satisfactorily attend to three hospitals, having to visit them once a month.

The Manhattan State Hospital, with its three branches, is to have but one board of visitation, and Long Island State Hospital, with two branches, one visiting board. One superintendent and one steward will officiate at the two hospitals on Ward's Island, and the other hospitals and branches will each have a superintendent and steward. The visiting boards will report to the Governor and to the State Commissioner in Lunacy.

Thus it will be observed that the changes made are trifling, and do not affect the main tenor of the Governor's original suggestions. These alterations will meet some of the objections brought against the bill at the hearing on January 22, but the control of the patronage connected with the hospitals will remain in the hands of the Governor and the State Commissioner in Lunacy, the powers of the local boards of visitation being restricted to visitation and inspection.

In fact, the real authority will be centralized at Albany.

The grounds upon which well-founded objections may be advanced against this scheme are that, if carried out, the State hospitals will be virtually brought within the domain of politics. The boards of managers who have up to the present time supervised the institutions for the insane have been, at any rate, outside politics. They have received no pay, and have performed their duties faithfully and well in the cause of charity alone. Perhaps their management has not been at all times distinguished by close economy, but some extravagance, when it directly benefits the patients and those attached to the institutions, is preferable to cheese-paring methods of conducting such establishments upon political lines.

Again, if reforms be needed, they can surely be introduced under the existing régime, and without proceeding to so extreme a measure as to overturn the entire system.

The boards of managers have done efficient service in the past, and no valid reasons have been forthcoming that their freely given services should be abruptly dispensed with.

SMALLPOX RASHES.

MM. H. ROGER and E. Weil, writing in *La Presse Médicale*, on the prodromal and secondary eruption of smallpox, say, that the cases admitted under their care numbered 928, rashes being observed in 171, or 18.42 per cent.

The frequency of such rashes was not the same in the two sexes. Thus of 235 males, sixty-two, or 14.48 per cent., had rashes, and of 493 females, 109, or 22.1 per cent. While rashes occurred in all types of the disease, their frequency increased with the severity of the attack. They were most frequent in hemorrhagic cases, being noted in rather more than 47 per cent. of such cases compared with a percentage of less than 13 in cases of varioloid. In unmodified attacks other than hemorrhagic, the percentage differed but little from 20 in all forms, irrespective of the termination of the cases.

The authors state, with regard to individual rashes, that six varieties were recognized—namely, the erythematous, the urticarial, the morbilliform, the scarlatiniform, the purpuric, and the astacoid. The erysipelatous described in standard text-books was not observed by them. The above rashes are described as follows:

"The erythematous rash is in the form of uniform red patches, disappearing on pressure.

"The urticarial rash consists of slightly raised wheals, white in the center, reddish at the edges, and usually associated with some itching.

"The morbilliform rash, much more frequent in occurrence than the preceding varieties, is an erythema, consisting of blotches, sometimes slightly elevated, in color a delicate rose tint, and peculiarly soft to the touch, the blotches being separated from one another by areas of normal skin. The rash has the exact appearance of measles. The blotches of the rash of smallpox are, if anything, a trifle larger and paler than those of measles, but the difference is in most cases too slight to enable a differential diagnosis to be made between the two diseases.

"In the scarlatiniform rash the skin of the affected parts is colored an intense red, which does not completely disappear on pressure. By a close scrutiny it will be found that the rash consists of two parts, a uniform coloration which disappears on pressure, and a fine speckling of a deeper hue, giving the skin a punctate appearance which cannot be entirely removed by pressure.

"The astacoid (Greek ἀστακός, color of boiled lobster) rash differs materially from all the former. Those already described may be met with in any type of the disease, but the astacoid rash is never encountered except in cases of the hemorrhagic type, and its appearance is a certain indication of a fatal result. The other rashes, even when general, are practically never seen on the face, while the astacoid is almost always present there as well as in all other parts of the body, so that the patient resembles a boiled lobster. It is not, according to the authors, as has sometimes been described, a generalized purpuric eruption, but a uniform coloration, a diffused sanguineous extension. In certain cases, however, parts of the body are free from the rash, and areas of healthy skin may be found on the lower parts of the thighs, on the legs, or on the forearms. In some regions, the color may be of a deep red, in others of a purplish hue, lurid, or even petechial. When it is added that the face is slightly turgid, that subconjunctival ecchymoses soon appear, followed by multiple hemorrhagic spots, or even subcutaneous hemorrhages sufficient to produce large bullæ, it will be understood that the patient presents an appearance the like of which is seen in no other disease."

The foregoing descriptions of the rashes of smallpox are vivid, and doubtless in the main correct, and convey a good idea of the difficulties with which the medical practitioner has to contend in making a diagnosis of smallpox in its early stages.

The fact, however, must be borne in mind that even at MM. Roger and Weil's estimate prodromal rashes are only observed in less than 20 per cent. of smallpox cases, and it is probable that as a rule they do not occur so frequently.

MM. Roger and Weil go on to say that these rashes almost invariably precede the true eruption, appearing on the first or second days after the onset of the attack, lasting for from twenty-four to forty-eight hours, and usually disappearing with the appearance of the eruption. The purpuric rash lasts longer, and does not disappear until it has gone through the changes common to hemorrhages in the process of absorption.

Notwithstanding the comparative infrequency of the occurrence of prodromal rashes in smallpox cases, the subject is important and the physician who is able, with more or less certainty, to differentiate between the rashes which sometimes usher in smallpox and those of the affections which they simulate, has a great advantage over the practitioner who cannot do so.

Early diagnosis of smallpox is universally allowed to be of vital consequence, and accordingly as accurate knowledge as possible of the prodromal rashes cannot but be of the greatest service in checking the spread of the disease.

THE INJECTION OF SOLIDIFYING OILS INTO THE TISSUES FOR MECHANICAL PURPOSES.

A great deal has been written and spoken of late regarding the injection into the tissues of solidifying oils, the purpose being to effect some mechanical end—occlusion of blood vessels, narrowing of ducts, inhibition of spasm in muscles, filling out of cavities, making good tissue deficiency consequent upon deformity, operation, or disease, the prevention of the union of various structures—nerves, muscles—after section, and so on.

The MEDICAL RECORD, having already made note of some of the uses to which the principle has been put, has received a number of letters from interested correspondents, requesting that more light be shed on the subject. Agreeable to these requests of our subscribers and contributors, we have had the field carefully gone over, the following being a condensed account of the whole matter.

Oils—liquid paraffin and the like—have been used hypodermically for a long time, as simple vehicles for suspended insoluble medicaments, notably in the management of syphilis. They have also been used for their nutritive value, real or supposed, as any one can find out for himself by consulting the catalogues. These uses, however, while they seemed to show the essentially bland and non-irritating character of the liquid oils themselves, have nothing in common with the employment of solidified oils for mechanical purposes, a later and altogether different idea.

As a matter of pathological interest, it may be noted, by the way, that as long ago as 1889 it became apparent that pulmonary embolism might result almost immediately from injections of liquid oils in this way—doubtless because of the entrance of the non-solidified oil into a vein. This accident, when not promptly recognized, has often been taken for pleurisy, but it is gratifying to note that, despite the threatening character of the symptoms, the outlook, so far as a fatal termination is concerned, is quite favorable. There is no doubt that such accidents deterred many otherwise favorably inclined to it from using this method of administering medicinal substances, especially in the management of syphilis. Moller, however, the chief advocate of it, is inclined—not altogether justly, we think—to perceive in the coarse granules of the suspended mercurials the chief cause of the embolism. Such an accident has, in fact, quite recently been seen to follow the injection of melted vaseline alone.

We come now to a radical departure in the method and purpose of employing oils in the tissues.

As long ago as 1891, Dr. J. Leonard Corning published a paper on the "Localization of Remedies about the Sensory Nerves of the Skin" (*New York Medical Journal*, December 26, 1891). To give effect to his purpose, which is sufficiently indicated by the title of his paper, Corning made use of a double-barreled syringe, the smaller barrel containing an aqueous solution of the medicament (anæsthetic, etc.), the other and larger one a solidifying oil. The aqueous solution was first injected into the skin, and immediately followed (through the same needle) by the introduction of the oil. A spray of ether or other refrigerating medicine was then thrown upon the injected region, which caused the instantaneous solidification of the oil in the tissue, and consequent occlusion of the blood vessels, thereby insuring the prolonged sojourn of the medicinal solution *in loco*.

This procedure, unique and ingenious as it is, is the forerunner of the principle which, now thoroughly established, was later applied by the author in a modified and still more striking manner.

About this time, having ascertained that by employing a firmer fat, *i. e.* a fat with a higher melting point, it (the fat) would remain permanently in the tissues.

This fact aroused in him the belief that if a melted oil of this kind were injected into a muscle affected by spasm, and then precipitated by cold, the convulsive condition might be arrested. In course of time, a proper case presenting (spasm of the splenius), he put his theory into practice with complete success even going so far as to give the procedure a special name—elæomyenchysis (The New York *Medical Journal*, April 14, 1894).

A third, and in some respects, the most ingenious of Corning's contributions in this field was published in the Medical Record of December 5, 1896. In that paper, an extension of the principle already enunciated by him, the author introduced the melted oil between the subcutaneously divided ends of sensory nerves (the great and small occipital and the auricularis magnus), and then solidified it as before, by the application of cold. A small knife having a cannula in the back was employed both for the subcutaneous division of the nerve and for the injection of the oil. The results obtained were very satisfactory.

Corning has also successfully injected solidifying oils in and about a small tumor that gave rise to pain by pressing upon a sensory nerve, thus preventing its growth by shutting off the blood supply ("Reference-Book of Practical Therapeutics," by Frank P. Foster, D. Appleton & Co., New York, 1896, Vol. I, p. 356, Article: Elæomyenchysis).

In the *Zeitschrift fur Heilkunde* for 1900, surgical number, Gersuny, under the caption "Ueber eine subcutane Prothese," states that melted vaseline, when injected into a yielding tissue, forms a small tumor, which remains *in situ*, causing no appreciable reaction. Profiting by this knowledge he has injected this oil to overcome various adverse conditions—the deformity incident to castration, blemishes due to cavities, depressed scars following bone operations, etc. He has also caused artificial narrowing of orifices in this way.

In the *Centralblatt für Gynäkologie*, 1900, No. 48, Pfannenstiel reports a case in which he resorted to the injections as practised by Gersuny; and not only was there little or no success, but an oil embolism precisely like that described by the syphilographers supervened. The distinctive symptoms were cough, chill, headache, vomiting, and accelerated respiration, followed twenty-four hours later by dyspnœa and cyanosis. The subject remained ill for about a week.

Meyer of Berlin has also commented on Gersuny's proposals, while Moskovicz, on behalf of his chief Gersuny (*Wiener med. Wochenschrift* of June 20, 1901), has given a full account of the procedure, wherein he refers to the mild inflammatory reaction taking place before encapsulation.

More recently the method has been used to obliterate smallpox marks, restore contours of saddle-nose, and to prevent reunion of nerves after neurectomy.

From this testimony, derived from a careful examination of medical literature appearing since the invention of the hypodermic needle, it is clear that the credit for the idea of the mechanical employment of oils in the tissues belongs wholly to Dr. Corning. And not only is this true, not only is he entitled to the honor of originating the principle, but also to credit for developing a method far more scientific than that of any of his followers; for even to the merest tyro in pathology it must be clear that by the immediate solidification of the injected oil by cold, as originally recommended by him, the possibility of the occurrence of oil embolism is immeasurably reduced. In any future application of the principle these facts should not be forgotten.

A Bill to Increase the Efficiency of the Medical Department of the United States Army.

At a recent meeting of the army medical officers stationed in Manila the following bill was adopted, and a committee was appointed to draw up a report to accompany the same, and to transmit the bill and memorandum to Congress for its consideration:

"Be it enacted, . . . that from and after the approval of this act, so much of Section 18 of act 4300, approved February 2, 1901, as provides as follows:

"Eight assistant surgeons-general, with the rank of colonel; twelve deputy surgeons-general, with the rank of lieutenant-colonel; sixty surgeons, with the rank of major; two hundred and forty assistant surgeons, with the rank of captain or first lieutenant, shall be and is hereby amended to provide as follows:

"Ten assistant surgeons-general, with the rank of colonel; twenty deputy surgeons-general, with the rank of lieutenant-colonel; eighty surgeons, with the rank of major; two hundred and ten assistant surgeons, with the rank of captain or first lieutenant.

"Provided, that all the other provisions of the said Section 18, act 4300, shall remain in force, and that nothing in this bill shall be held or construed to change any other portion of said act 4300; approved February 2, 1901."

The memorandum accompanying the bill proposed above is signed by the committee on legislation, consisting of Lieutenant-Colonel P. F. Harvey, Deputy Surgeon-General; Major L. M. Maus, Surgeon; Major L. W. Crampton, Surgeon; Capt. M. W. Ireland, Assistant Surgeon, and First Lieutenant J. J. Reilly, Assistant Surgeon. The memorandum states that the object of the proposed bill is to provide for a more satisfactory rate of promotion, such as would serve as an inducement for capable and desirable young medical men to enter the medical department of the army. The memorandum says: "The law now in force provides for such a large number of the lower grades and small number of the higher that it has been found impossible to induce a sufficient number of candidates to present themselves for admission to the medical corps. There are, at the present writing (November 18, 1901), about seventy vacancies, and although since the passage of the act approved, February 2, 1901, examining boards have lowered the standard of examinations, there appears no prospect of a possibility of attracting a sufficient number of properly qualified young men considerably to reduce this very large percentage of vacancies."

The memorandum recites the fact that the medical department has been severely discriminated against, as regards promotion, as compared with other branches of the military service, and shows that while previous to the act passed last year the medical officer could hope to become a major in eighteen or twenty years, and of becoming a colonel at the time of retirement, under this act the young medical man now entering the army can never hope to attain a higher grade than that of major, even after as much as forty years' service, and that the greater portion of such new appointees would probably retire with the grade of captain. "These facts are fully appreciated by the younger physicians of our country and by the volunteer and contract medical officers, hundreds of whom are now serving with troops, and they are declining to become candidates for a position offering such an unpromising career and so little in the line of promotion and emolument."

The memorandum goes on to state that the regrading proposed in the above bill merely restores the rate of promotion as it existed for many years prior to February 2, 1901, and shows the position in which the officers of the proposed higher grades could be utilized. "The readjustment of grades proposed will provide for satisfactory promotion and induce worthy civilian physicians, volunteer, and contract surgeons to present themselves for admission to the corps, who are now deterred from doing so by the gloomy outlook. It is believed certain that unless the relief asked for is bestowed the corps cannot be filled with well-qualified physicians, and the medical service will be seriously embarrassed."

Printed copies of the proposed bill and the accompanying memorandum have been widely distributed among those who might be interested and in a position to assist in securing favorable action by Congress on the proposed regrading of the medical corps. It is said, however, that the authorities in Washington who secured the passage of the act of February 2, 1901, in opposition to the earnest protests of the medical department, are unwilling to have the matter reopened at this session of Congress, and insist that their plan shall be given trial for a year longer. The military committees of the House and Senate have also announced that there would be no army legislation during the present session of Congress, so that the action of the medical officers in Manila will probably amount, for the time being, to little more than making an existing defect a matter of record.

Titles for Medical Officers.

In this country and in Great Britain there has been for some time much dissatisfaction with the manner in which the medical officers are treated by the authorities.

In both countries military titles have been accorded to the army surgeons, but it seems there still remain various causes for complaint.

Some surgeons in the army are by no means grateful for their recognition as to rank, but would prefer to be styled simply doctor, holding that to grant a medical man military rank is somewhat of an anomaly.

Captain John Stewart Kulp, in the *Army and Navy Journal*, January 18, explains lucidly why it is fitting that an army medical man should have a title.

He points out that in our country the title of doctor is borne not only by graduates in medicine and surgery, but as legally by dentists, veterinarians, preachers, and by the graduates of some schools of science and pharmacy. In addition, it is attached to Christian Scientists, osteopaths, eclectics, faith curists, root doctors, as well as to the magnetic healer, and the good ship's cook. Then, it is also bought and sold.

Captain Kulp also draws attention to the fact that the use of the military title is now universal in the English medical service and in the sanitary service of the French army, and adds: "Some of us think that because we are medical men doing purely medical duty, it is better that the different grades which we have reached by service and real examinations be recognized by our superiors and subordinates, and that it is unwise for the contract surgeon and the officer of thirty years' service to bear the same title."

The conferring of titles upon military surgeons would seem to be warranted in view of the duties which they are called upon to perform. They are an essential part of the military organization of a country, and there is no reason they should clash with or usurp the prerogatives of the army officers pure and simple. To each department are allotted its special duties, and if by giving the military medical officer a title his powers for doing good work are rather increased than diminished, and his *amour propre* is gratified, then any argument against this course falls to the ground.

Vaccination and Smallpox.

Dr. J. S. Hunt, President of the Board of Health of Easton, publishes in the Easton *Express* a review of the benefits conferred upon the community by the adoption of vaccination.

At the present time, when smallpox is widely spread through the whole country, it is desirable that the facts concerning vaccination and smallpox should be heralded everywhere.

Dr. Hunt gives the following statistics with regard to vaccination in Germany:

"In Germany every child is vaccinated at or before it is two years of age, and again revaccinated when it enters school. It would seem that if we were wise and prudent we would follow the German custom, for there were only twenty-eight deaths from smallpox in Germany in 1900, which has a population of 54,000,000. A good example of the value of vaccination is found in the German and French armies. When Paris was besieged by the Germans in 1873, there were about a hundred thousand men in the German army. Germany required of her soldiers compulsory vaccination, while France didn't. While the French army lost over 23,000 by smallpox, the Germans lost less than 100. Compare the death rate from smallpox in Germany and Philadelphia. Why, in Philadelphia they lose more in a month by death from smallpox than Germany loses in a whole year."

Dr. Hunt then proceeds to insist upon the necessity of efficient vaccination. A most important point and, as suggested in the Medical Record recently, a probable cause of the prevalence of smallpox.

Evasion of vaccination is culpable, if not criminal, and the physician should always be firm in his determination to vaccinate thoroughly.

Vaccination is not only a question affecting the individual, but the entire population of a country.

Havana, the Healthful.

The reproach has been taken from Havana, and in place of being shunned and loaded with obloquy, the capital of Cuba now takes a position among the salubrious cities of the world.

According to the report of Major Gorgas, the death rate of Havana in December last was 20.47 per 1,000. In December, 1900, it was 23.28.

In December, 1899, 534 deaths occurred; in December, 1900, there were 488 deaths, and for the same month, in 1901, the deaths only numbered 463, a very satisfactory progressive decrease. The city was free from smallpox or yellow fever in December last, and Major Gorgas expresses the opinion that it is not likely to appear in the near future.

The work of exterminating mosquitos, however, is proceeding briskly. The "Stegomyia" brigade is pursuing its operations within the city limits, while the "Anopheles" brigade is doing its best to clear the suburbs of the malaria-bearing mosquito.

The condition of the city with regard to mosquitos is reported to show much improvement.

Major Gorgas rightly lays a great deal of stress upon the disappearance of yellow fever during October and the two following months, an event which has not happened within the memory of the oldest inhabitant. This would appear further to substantiate the correctness of the findings of the American army doctors as to mosquitos and yellow fever, for as Major Gorgas points out in the years 1899 and 1900 every known means was employed to destroy fomites, but until this past year, when similar exertions were put forth to exterminate mosquitos, yellow fever was present to a greater or less extent.

The sanitary rehabilitation of Havana is a monument to American science and energy.

Sanatoria for Consumptives.

All the medical and many of the lay journals have long been urging the crying need of sanatoria for indigent consumptives. The slowness of the United States to follow the example of Europe in establishing such institutions has been made the subject of much unfavorable comment.

Germany has a magnificent sanatorium system, and most of the countries of the European Continent possess some institutions to which the needy sufferer from tuberculosis can betake himself and receive treatment after the most approved fashion.

In Great Britain institutions of this kind are springing up everywhere throughout the land. London has for many years possessed hospitals especially for consumptives, and will soon erect a magnificently equipped sanatorium for the treatment of this disease.

The United States, however, has been up to the present tardy in providing buildings in which those who are unable to pay for treatment may receive the care and nursing which their condition requires.

Dr. Knopf, in the New York *Herald*, January 26, has this to say on the matter:

"A State sanatorium in the United States means an institution for the exclusive treatment of patients suffering from pulmonary tuberculosis, created by the funds of the State, and supported entirely or in part by the State." The first State sanatorium in America was erected a few years ago near Rutland, Mass. Recently other States, New York, New Jersey, Iowa, Illinois, Maine, etc., have projected the building of similar institutions.

Dr. John H. Pryor of Buffalo publishes in the Medical Record, January 25, the report of the Committee on Sanatoria for Consumptives, in which the whole question of State care of these sufferers is ably discussed.

New York has been too long negligent of her responsibility with regard to consumptives, but she has yet the opportunity of atoning for her sins of omission.

The question should be attacked in no spirit of niggardliness, for it must ever be borne in mind that tuberculosis is more or less of a public menace, and the truest economy will be to banish consumption regardless of cost.

The Osteopath Bill.

Opposition to Senator Brackett's bill to legalize osteopathy is assuming large proportions among the members of the medical profession of this State, and physicians are preparing to fight against its enactment tooth and nail.

There is no doubt that if the lay community had a clearer conception of what the passing of such a measure really means, many who now are in favor of osteopathy, or who regard it with lethargic interest, would take active steps to prevent the bill in question from becoming law.

The bill gives to a class of people with no adequate medical or surgical training the right to treat disease, to attend midwifery cases, to sign death and birth certificates, and, with the exception that it restricts them to the practice of their own methods, places them on an equal footing with regularly licensed physicians.

The teaching and training at the osteopath colleges is flimsy and superficial, in most respects farcical, and it would be a gross injustice to place their graduates legally on the same plane as the medical practitioner who has expended much time and money in rendering himself competent to practise.

At the same time, the general public will be, in the long run, the chief sufferers, for the passage of the Brackett bill would enable incompetent men to practise their medical art without let or hindrance upon the bodies of those who might be sufficiently foolish to trust themselves to osteopathic treatment.

The legalizing of osteopathy, too, would assuredly have the effect of encouraging quacks of every description to attempt to gain a license, and might result in flooding the country with persons ignorant of medical knowledge, but with legal qualifications to treat disease.

It would be well that New York State should set the example to other States of refusing to countenance the passage of laws permitting osteopathy to take rank with legitimate medicine.

Preservation of Forests in Massachusetts.

The deplorable destruction of forests in the United States is becoming a highly serious matter, and the President's well-timed reference to it in his message should bear good fruit.

Massachusetts has taken time by the forelock, and a few years ago the State joined hands with some public-spirited citizens to preserve sections of beautiful woodland in the vicinity of Boston.

Their efforts have been attended with great success, and large tracts of forest land have been rescued from the ruthless lumberer.

There are also other forest reservations in various parts of the State, outside the jurisdiction of the Boston Metropolitan Park commissions, and which are looked after by special commissions.

Massachusetts, in addition to caring for the preservation of forest tracts for the enjoyment of the public, has regarded the subject from the commercial standpoint.

The Massachusetts Forestry Association, according to the New York *Tribune*, is organized chiefly to secure the preservation of the present forests through the education of the farmers into the knowledge that forestry pays. It is also the aim to secure the enlargement of the present acreage of forests by planting with trees the 250,000 acres of idle land within the limits of the State.

The suggestion has been made recently by an able writer that an immense region of forest land in

Minnesota should be reserved by the Government as a national park.

The MEDICAL RECORD has always advised that trees should be spared as much as possible from a business as well as a health point of view.

The action of Massachusetts and of some other States would seem to show that the authorities are becoming alive to the necessity of preventing the further wholesale destruction of forests.

SENATOR PLATT'S LEPROSY BILL.

The following are the salient features of a bill to control the spread of leprosy, introduced in the National Legislature by Senator Platt of New York:

The appointment of a leprosy commission to reside at New York or San Francisco, to get a yearly salary of $5,000.

The setting aside of a mile square for a national leper home, the site to be chosen by a leprosy board.

The appropriation of $50,000 to erect suitable buildings for the habitation of lepers in the United States, not including Hawaii, Porto Rico, Cuba, or the Philippines.

The transportation of lepers who are unable to care for themselves to the National Leper Home.

The injunction of steamship companies or individual vessels or railroads to bring to the United States any leper, or to accept any emigrant from any of the countries known to be leprous without a special certificate.

The strict supervision for seven years of immigrants of leprous families, though they themselves be free of the disease.

The deportation of any leper, who, despite all precautions, manages to enter the United States. No discrimination to be made in behalf of Americans who contract the disease in a foreign country.

The Marine Hospital Service of the Treasury Department to have full charge of the National Leper Home.

This bill should have the effect of checking the spread of leprosy in this country. With regard to the contagiousness of leprosy opinions differ; some believe that it is so in a high degree, while others hold that the disease can only be communicated under certain conditions.

However, in the case of a malady so loathsome as leprosy it is better to err on the side of caution than by any laxness to run even a risk of disseminating its germs.

Strict segregation is generally believed to be the only effectual way of restricting the scope of leprosy, so that an appropriation of $50,000 for this purpose would be money well spent.

Acute Appendicular Pneumonia in Children.—R. Massalongo reports four cases of pneumonia in children which began with all the symptoms of appendicitis. Five other cases he has heard of in which operation was performed, only to find a perfectly normal appendix. The differential diagnosis is not easy; pneumonia is often ushered in by colicky pains, especially in the abdomen, and frequently has a most insidious onset. Moreover, appendicitis is sometimes accompanied by pulmonary complications, and there are symptoms common to both diseases, due to infection of the organism by some microbe—pneumococcus or streptococcus in pneumonia, colon bacillus or streptococcus in the majority of cases of appendicitis. A better name for the affection under discussion than the one given in the title would be acute pneumonia with appendicular onset, or pneumonic pseudo-appendicitis.—*La Riforma Medica.*

News of the Week.

The Board of Health Vaccines.—A very healthy discussion has arisen concerning the manufacture of vaccine virus and diphtheria antitoxin by the Board of Health of this city, the disasters following the use of the city antitoxin in St. Louis being the exciting cause. Two societies have recently debated the question and have come to diametrically opposite opinions. The New York County Medical Association recently appointed a committee to investigate the process of manufacture by the Health Board, and this committee has made a report that everything is done properly, and that the vaccine and the antitoxin furnished are thoroughly reliable and safe. A few days after this report, the New York County Medico-Pharmaceutical League held a meeting in which a number of speakers attacked the Health Board methods, and denounced the sale of city vaccine and antitoxin. It was said that the calves and horses had, until very recently, been kept in underground stables, and that the assistants were incompetent and were frequently changed. The question as to the purity of the Health Board's vaccines seems to have been brought no nearer a satisfactory answer by these reports than it was before. The report of the County Association committee was not at all reassuring, for the investigation seems to have been of a more or less perfunctory character. On the other hand, the attack of the Medico-Pharmaceutical League was weak, and bore the appearance of having been inspired by a bias in favor of private manufacturers. The President of the Board of Health denies the accuracy of the criticism of the department's methods of manufacture and refers to the report of the other society. The Academy of Medicine might silence some of the criticisms which have been recently brought against it by correspondents in our columns if it would undertake a thorough investigation on its own account by a committee of competent bacteriologists and clinicians, free from any possible bias and courageous enough to state its conclusions freely without regard to the feelings of any one. It is possible that the report of such a committee would be accepted as satisfactory by the medical profession of the city, and the interested and now somewhat alarmed lay public.

The Stony Wold Sanatorium.—At the first annual meeting of the Stony Wold Sanatorium Association, held last week in this city, it was announced that money enough has been raised to warrant the beginning of work. The Lake Kushaqua property, where the institution will be situated, was bought last September. It is in Franklin County, at an elevation of 1,730 feet above the sea, and comprises about 1,200 acres. The style of architecture will be the same as that of the Massachusetts State Sanatorium, which is considered a model of its kind. The plans call for a three-story administration building, on either side of which will eventually be erected four dormitories two stories high, each containing twenty-five rooms. The erection of the administration building will be begun this spring, and it is hoped that this building and one dormitory will be completed by November 1, 1902.

Suggested Changes in Medical Education in Michigan.—The Michigan State Superintendent of Public Education, Professor Delos Fall, makes the following recommendations in his last annual report concerning medical colleges in the State. "A standard of preliminary education should be required, and a board created to examine all students before entering upon the study of medicine. Some safe, uniform standard for graduation ought to be fixed and insisted upon as a condition precedent to a license to practise medicine.

The financial solvency and stability of each institution should be more carefully guarded and insisted upon. Medical colleges should not be chartered in small towns where clinical and hospital facilities, so necessary to the proper education of a physician, are not ordinarily found. A constant and thorough visitation and inspection of such institutions should be regularly made by a board of visitors competent fairly to judge of their merits. The capital of every medical college should be large enough to warrant the employment of men learned in their profession, and the provision of equipment in all branches adequate to promise a proper medical course."

The Loomis Laboratory.—The Supreme Court has dismissed the suit of the New York University against the Loomis Laboratory to gain possession of its property. Colonel Payne, who gave the money to build and equip the laboratory, testified that his purpose was to build a laboratory for original research and elementary teaching in scientific medicine, and that this laboratory was to be entirely independent of the New York University, being governed by five trustees. The court decided that the fact that the laboratory was for a time used in connection with the instruction given in the medical department of the New York University did not give the latter any right of possession in it, nor entitle the students of the university to its use without the consent of the trustees.

The Health of Immigrants.—In the immigration bill introduced early in the present session of Congress is a section which makes it unlawful for any transportation company or the owners, masters, or agents of any vessel, to take on board for transportation to the United States "any alien afflicted with a loathsome or with a dangerous contagious disease," and imposes a fine of $100 for each and every violation of the prohibition. It also is provided that the decision of the examining officer of the United States Marine Hospital Service shall be final, both as to the fact and nature of the disease, and on the question whether the disease existed at the time of embarkation. At present the only penalty for bringing passengers with any prohibited disease to this country is the necessity of carrying them back if the officials here refuse them admission. Sometimes steamship owners take aboard their vessels persons who they know are suffering from diseases which, if manifest to the inspecting officer on this side the Atlantic, will cause the immigrants' rejection here. In such cases it is customary for the steamship owners to require a deposit from the diseased individual sufficient to pay his way back home if he should not be allowed to land in the United States.

Hypnotic Reformation.—The President of the Board of Children's Guardians in Terre Haute, Ind., is said to have given his consent to a Chicago "professor of hypnotism" to experiment with the children in the home maintained by the board. The experimenter claims that by hypnotic suggestion he can start a train of thought in the minds of the children for better things. Children who have been taken from vicious parents will be experimented upon, and those concerned say it can do the children no harm and possibly will have good results.

New Cures for Consumption.—It is reported from Cracow that an engineer of that town has discovered a gas which he calls "electroid," and which he claims is inimical to the bacilli of tuberculosis. It is stated that several Polish physicians are prescribing the gas by inhalation, the séances lasting from one to fifteen minutes, and claim to have had excellent results, in combating the symptoms at least, if not in actually arresting the morbid process. In London, experiments are being carried on at the Brompton Hospital for Consumption in the treatment of phthisis by means of Tesla's high-frequency currents and the intravenous injection of a bacillicide. Dr. Symes-Thomson, in a recent lecture, said that favorable results have been observed to follow this treatment, and he spoke hopefully of the final extinction of the disease by means of this and other modern methods of treatment.

Insurance Against Smallpox.—In England it is possible to insure nearly everything from a long overdue ship to the life of the king. According to a Liverpool paper, an extensive business is now being done in the larger cities of England in insuring against an attack of smallpox. The premium is 2s. 6d. per cent. on recently vaccinated cases, and 3s. 4d. per cent. on persons who have not been vaccinated since infancy.

Dearth of Vaccinators.—The health commissioner is finding difficulty in getting additions to the corps of vaccinators urgently needed at this time, because of the increase of smallpox. Civil service restrictions prevent the appointment offhand of the necessary number of physicians, but physicians already in the employ of the city can be appointed by being transferred from one department to another. There is a large number of medical school inspectors, and many of these were appointed vaccinators. Most of the appointees have, however, refused to serve; for, although the salary is much larger, the hours of service are longer and the work is more arduous. But the main objection was that by becoming a vaccinator one would cease to be a school inspector, and so would be out of the department upon resigning or being dropped from the vaccinating corps. There is no eligible civil-service list from which the commissioner can draw, and it will be several weeks before examinations can be held and new appointments made. By that time extra vaccinators may not be needed.

The Hydriatic Department of the Riverside Association.—This association is a society in New York organized with the aim "to help the poor to help themselves." It maintains a gymnasium, kindergarten, clubs for boys and girls, a penny provident fund, sewing and cooking schools, and public baths. In the latter is included the "Hydriatic Department," designed for the water treatment of indigent patients sent by physicians or other dispensaries. Dr. Simon Baruch, the medical director of this department, reports that during the past six years 1,848 male and 1,780 female (in all, 3,628) patients have been received for water treatment from 128 physicians and ten dispensaries. The number of treatments administered in 1895 was 2,146; in 1900, 12,945. This sixfold increase in six years, Dr. Baruch says, shows clearly the favorable results obtained, and the consequent rapidly growing appreciation of hydrotherapy in the management of obstinate chronic diseases. There were over thirty distinct diseases treated by this means.

Opposition to a Pest House.—A temporary injunction was granted last week restraining the city of East Orange from receiving smallpox patients in the new portable isolation hospital building, erected on the boundary line between East Orange, Vailsburg, and South Orange. The application was made by the pastor of a Catholic church and orphan asylum in East Orange, who alleged that the isolation hospital was a menace to the children attending his parochial schools, also the 200 and more orphans and caretakers at the asylum. His residence, he asserted, was within 900 feet, the distance required by law. The hospital was built in less than two weeks at a cost of several thousand dollars, and it [illegible] the time the [illegible] was [illegible]

Pathological Society of Philadelphia.—At a stated meeting held January [illegible], Drs. [illegible] and David Riesman exhibited a specimen of "Primary Carcinoma of the Liver and Thrombosis of the Inferior Vena Cava." The patient was an alcoholic in whom oedema of the lower extremities developed in the absence of evidence of disease of the heart or kidneys, with progressive enlargement of the liver and the appearance of nodules on its surface and also hemorrhagic ascites and enlargement of the abdominal veins. Dr H D Jump exhibited a specimen of "Primary Carcinoma of the Liver." Dr D J McCarthy presented a communication entitled "Experimental Osseous Formation in the Brain of a Cat." He cited observations showing that the introduction into the brain of fragments of bone with or without periosteum was followed by the development of bony tissue free from calcareous matter. Dr D L Edsall presented a communication entitled "The Relation Between the Glycouronic Acid and the Benzoyl Esters in the Urine in Diabetes." He cited observations tending to show that together with dextrose there occurred in the urine of cases of diabetes other products of carbohydrate metabolism. Dr W. G. Spiller exhibited a specimen of "Tumor of the Pons." During life the case had been variously diagnosticated as chlorosis, nephritis, exophthalmic goiter, and brain tumor. Cerebellar symptoms were absent, although the cerebellum was found greatly compressed. Tinnitus had been present as an early symptom, but it was attributed to ear disturbance, and the ossicles were removed for its relief but without effecting the desired result. A prominent feature, in addition to headache, nausea, and vomiting, consisted in convulsive movements of the face, from the presence of which operation was undertaken over the facial cortex. The patient survived but a few days, and after death a tumor was found displacing the facial nerve, while in the facial cortex marked round cell infiltration was found, and which it was thought was responsible for the convulsive movements rather than the irritation of the facial nerve. Dr. W. M. Coplin exhibited specimens of "Uterus, Liver, Bladder, and Kidney, with Sections, from a Case of Puerperal Septicæmia Due to Mixed Infection by the Cocci of Suppuration and the Bacillus Coli Communis." The patient was a colored woman, with a contracted pelvis, and craniotomy was required for the delivery of the fœtus. In addition to the local lesions, acute dilatation of the stomach was present, and on microscopic examination, fragmentation of the muscular coat of the stomach was found. Dr. J Alison Scott exhibited a specimen of "Tuberculous Mediastinal Tumor with Ulceration into the Œsophagus, Bronchi, and Pulmonary Artery."

The Late Dr. Clayton Parkhill of Denver, Colo.—The following resolutions have been adopted by the Medical Board of St. Luke's Hospital, Denver, on the death of Dr. Clayton Parkhill:

The medical and surgical staff of St Luke's Hospital is called upon to mourn the death of one of its most prominent members.

"Dr. Clayton Parkhill was appointed attending surgeon to the hospital in 1880 and served continuously in that capacity until his death. As a surgeon he was painstaking, intelligent, and careful, successful in his work, kind and gentle in the treatment of his patients; as a man, he was courteous and amiable, as a colleague, he was companionable and helpful.

Dr Parkhill was one of the most brilliant of operators, and the profession is indebted to him for many useful and practical surgical inventions. His counsel was eagerly sought by students and practitioners. As a writer he was clear and forcible, as a lecturer he was eloquent and thorough. He was, in truth, among the distinguished of American surgeons, and did much to shed luster on his chosen profession. At the breaking out of the Spanish-American War he was among the first to respond to the call of duty, and as a military surgeon he deservedly held high rank.

"The staff of this hospital desires to record its appreciation of his long and valuable services to the institution, and of his many endearing personal qualities, and it extends to his bereaved family and friends its profound sympathy.

"CHARLES A. POWERS,
"WALTER A. JAYNE,
"E. J. A. ROGERS,
"Committee."

Homœopaths Express Themselves in Favor of Vaccination.—At a meeting held January 20, the Germantown Homœopathic Medical Society recorded "its unqualified approval of the value of vaccination as a preventive of smallpox," and expressed itself as "heartily in accord with the effort of the Board of Health to secure universal vaccination."

Philadelphia Polyclinic.—Mr John Scott, Jr., has been elected President of the Board of Trustees in succession to Mr W. T Donovan, resigned. Dr George C. Stout has been elected Professor of Diseases of the Ear in succession to Dr. B Alexander Randall, resigned.

Philadelphia County Medical Society.—At a stated meeting held January 22, Dr Jas. P. Mann exhibited "A Case of Multiple Symmetrical Exostoses" in a man twenty-four years old, in whom the abnormality had begun at the age of three years. Major Louis La Garde, Surgeon United States Army, by invitation read a paper entitled "Gunshot Wounds of the Knee by Reduced Caliber Projectiles." He pointed out the reduced mortality and the greater restoration of function resulting from the small-caliber steel missile of swift velocity employed in recent years as compared with the larger caliber softer missile of slower velocity of an earlier day.

Dr Sherbourne W. Dougherty has been appointed United States medical inspector in the Philadelphia post office, in succession to Dr. James B Harwer.

High Death Rate in Philadelphia.—The number of deaths reported to the Philadelphia Bureau of Health for the week ended January 25 was 563, which was 61 more than for the preceding week and 27 more than for the corresponding week of the previous year. Typhoid fever and smallpox exhibit an increase in the number of cases and of deaths, there having been reported 117 cases of the former and 9 deaths, and 90 cases of the latter and 19 deaths. There were besides, 72 cases of scarlet fever and 3 deaths, and 65 cases of diphtheria and 10 deaths. The principal causes of death were as follows: Pneumonia, [illegible] cases, pulmonary tuberculosis, 72; nephritis, 42; diseases of the heart and pericardium, 41; inflammation of the stomach and bowels, 27.

Generous Bequests.—By the will of the late Wm. McClary of Philadelphia, the sum of $1,000 is bequeathed to the Protestant Episcopal Hospital, to endow a bed in his wife's name; $5,000 to the Presbyterian Hospital to endow a bed in memory of his sister-in-law; $5,000 to the German Hospital, to endow a bed in his own memory; $5,000 to St Joseph's Hospital, to endow a bed in memory of himself, and $5,000 to the Samaritan Hospital, to endow a bed in memory of his son.

Obituary Notes.—Dr. Francis Clemens, Jr., of Paoli, Pa., was drowned on January 1 in fording a stream, whose waters had become greatly swollen in consequence of the breaking of an ice gorge.

Dr. Andrew J. Hines died at Doylestown, Pa., on January 21, at the age of 76 years. He was graduated from Jefferson Medical College in 1853.

Dr. Amos B. Lewis, of this city, died on December 28, after an illness of several weeks' duration. He was fifty-nine years of age, and was a graduate of the Cincinnati College of Medicine and Surgery, in the class of 1871. He was visiting dermatologist to the Fordham Hospital.

Dr. Charles George Sproull, of this city, died after an operation for ileus on January 25. He was thirty-four years old, and was a graduate of the New York University Medical School, in the class of 1893, and served for two years as an interne at Bellevue Hospital.

Dr. Lachlan Tyler, of this city, died after an operation for appendicitis on January 26. He was fifty years old, and was a graduate of the College of Physicians and Surgeons, New York, in the class of 1876. Dr. Tyler was a son of former President John Tyler.

Dr. Dominick George Bodkin died at his home in Brooklyn, on January 26, at the age of sixty-nine years, after a long illness. He was born in Ireland, and was brought to this country by his parents in his childhood. At the breaking out of the Civil War he was a student in the New York University Medical School, but broke off his studies and volunteered in the army, and served as assistant surgeon on the staff of Gen. Canby. At the close of the war he resumed his medical studies and was graduated in the class of 1866. He resided for thirty years in the same house, which was known in that section of the city as "the doctor's house," and had a very large practice, his waiting patients, it is said, sometimes forming a line extending out into the street. He was a member of many local and national societies, and for many years was a member of the attending staff of St. Mary's Hospital.

Dr. Robert B. Grimes died at his home in Cheyenne, Wyoming, on January 27. He was a graduate of the St. Louis Medical College in 1869. Dr. Grimes was a veteran of the Civil War and an Indian fighter. He was a member of the Thornburg party that went to the relief of the White River Agency in September, 1881, and was one of the few who survived the massacre.

Case of Resection of Two-thirds of the Liver for Angioadenoma.—Carl Beck describes the case of a young man, twenty years of age, suffering from a tumor in the left epigastrium, which was of the size of a man's head. It was movable to a certain degree, solid, somewhat irregular, and not especially tender, and by percussion was found to extend into the liver. The diagnosis was between tumor of the kidney, pancreas, omentum, or stomach. But when the abdomen was opened, the tumor was found to be continuous with the liver, taking in entirely the left side of the liver, the right lobe being extremely small; with some difficulty half of the tumor was removed, the other half being left to slough off. The after-treatment consisted in removing the sloughing portions gradually until there was nothing left but a small pedicle. From all spaces of the sloughing tissue there escaped bile for two or three weeks. The patient made a good recovery, and the right portion of his liver is enlarging, so that it may yet give him good hepatic function. The tumor was found to be an angioadenoma. The prognosis as regards recurrence is favorable, neither adenoma nor angioma being tumors that recur, as a rule. —*Chicago Medical Recorder.*

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

KING EDWARD'S MODEL SANATORIUM FOR TUBERCULOUS PATIENTS—POSTPONED HONORS—CORTICAL LOCALIZATION IN THE HIGHER APES—LADY HOUSE SURGEON RETIRES—SUGGESTION FOR A CANCER CONGRESS—SMALLPOX.

London, January 3, 1902.

An anonymous philanthropist has placed at the King's disposal for charitable or utilitarian purposes a sum of about £200,000, and His Majesty has decided to apply it to the establishment of a sanatorium for tuberculous patients.

To carry out his purpose, the King has appointed an advisory committee of medical men, and has already sanctioned the expenditure of £800 in prizes for the three best essays and plans of a model sanatorium. The prizes of £500, £200 and £100, respectively, will be open for competiton to the medical men of all nations.

It is intended that the King's sanatorium shall provide one hundred beds, fifty for each sex; of these twelve beds are to be set apart for well-to-do persons, who desire to try sanatorium life, while the others will be at the disposal of persons who can contribute only a small proportion of the cost of their maintenance. The institution will be fully equipped with all requirements for research, it being understood to be the desire of the King that his sanatorium should be as perfect as our present knowledge can make it.

I hope a firm hand will be kept on architects' ambitions, so that the money may not be all squandered on buildings. There are several object lessons on the extravagance of architects standing, which the advisory committee might profitably study.

There was no distribution of honors on New Year's Day—to the disappointment of some aspirants. But it will make little difference. The change in the custom will be merely a change of dates. The King's birthday being in November, it is almost too soon for another set of honors, and the next will most assuredly be at the Coronation. Those who are sure of being on the list can very well wait till then. Those who are not, have a little longer to prove their worth to their country.

Localization in the motor cerebral cortex was brought before the Pathological Society on the 17th ult., in a paper by Professor Sherrington and Dr. Grünbaum. These experimenters have investigated the subject, using the higher apes, and in some points have been obliged to correct some statements of their predecessors, at any rate, so far as these animals are concerned. They have laid all the known species of anthropoid apes under contribution, but the majority of their experiments were on the chimpanzee. In this animal the extent and arrangement of the motor area certainly differs from that described by other observers in the lower apes and the orang. They examined nineteen hemispheres. One point clearly results: that the anterior limit of the motor region does not coincide with any fissure. The value of the fissures as landmarks to the topography of the functional centers is thus impaired so seriously as to become useless. The patterns exhibited by the convolutions and sulci of these richly convoluted brains differ so much that hardly a pair are exactly alike. The fissures, therefore, are not physiological boundaries.

The ease with which faradism elicits movements from this cortical region of anthropoids at first surprised the experimenters, considering the intensity reported to be required in man, and it is suggested that if that intensity is really required, it constitutes a difference between the motor region of man and that of the anthropoid and lower apes.

Another interesting difference from former observations relates to the production of epilepsy. Drs. Sherrington and Grünbaum found this easily produced in the majority of the animals on which they experimented, though in some individuals the tendency was slight, in others it was strong, the condition being the same.

The sequence of representation of movement observed followed a plan more in accordance with the order of the spinal segments than that previously obtained.

Another notable discrepancy, the experimenters have never seen anything to lead them to include any part of the surface of the postcentral convolution in the motor area of any of the apes they employed. Strong currents on the postcentral showed no movements. Weaker currents on the precentral evoked widespread movements. Small lesions in the precentral convolution caused marked paralyses and regenerations; similar larger lesions in the postcentral gave rise to neither.

Miss Clark has at length given up the contest with [illegible] Happily, too, the [illegible] and, standing together, refused to be ridden over roughshod by the board.

Miss Clark may herself have learned a useful lesson and will perhaps not again attempt to [illegible] with the majority of the people. If she could imagine herself a medical man who in some way had occupied a position in which all his colleagues refused to recognize him, she might further imagine what a union would do in such case. Then she will congratulate herself that she has withdrawn from an untenable position.

The Cancer Society wants to get up an international congress on the lines of the recent tuberculosis congress. Perhaps it is rather too soon for another congress [illegible] and the society has not, I believe, at present sufficient [illegible]. By waiting a little its members will have a better opportunity.

The march of smallpox continues. There were twenty-four fresh cases yesterday, and thirty-nine the day before. Fresh districts are being invaded. There are now over 500 cases under treatment. An unfortunate error of diagnosis has in one or two instances caused the infection to spread in a family. One borough council has ordered chickenpox to be notified, with a view of preventing mistakes. A return case from one of the [illegible] is reported to have renewed the infection in one family. In another instance a case was at first treated as blood poisoning by a doctor who was unfamiliar with smallpox, and visitors were admitted to the patient's room, adding to the difficulties of prevention. At Reigate there has been quite a run on [illegible] lymph, [illegible] which the antis [illegible]. I hope [illegible] will not be a [illegible].

LETTER FROM NEW ZEALAND

(From Our Special Correspondent.)

(ABORTIONISTS—OPIUM SMOKING—VITAL STATISTICS.)

AUCKLAND, N.Z., December 20, 1901.

THE police in this colony are making a dead set at the abortionists. Every criminal [illegible] three or four [illegible], but it is very rare that a conviction can be obtained. Popular sympathy is [illegible] on the side of the accused, and, however clear the evidence may be, [illegible] in the large majority of cases. The case I mentioned in my May letter in which a well-known and fully qualified surgeon was accused of causing the death of a young woman by an operation, which was followed by [illegible] after three trials [illegible]. On two previous trials before the Supreme Court the jury had disagreed [illegible]. The accused [illegible] from May 18 to November 27, [illegible]. The evidence given on behalf of the accused clearly proved that the deceased could not have been present at the offices of the accused on the only afternoon on which the operation could have been performed. The case was of the most flimsy description [illegible] by a woman of very bad character, suffering agonies of pain, and most probably affected by brandy, which is invariably given by the lower classes for any abdominal pain. She was asked if she had seen Dr. ——, and, after first denying, then affirmed that she had, and that he had operated on her. There was not the slightest trace of any operation.

The new bill to prevent the smoking of opium passed the general legislature in the closing days of the session. One conviction has already been obtained against a man for importing opium for smoking. He was fined [illegible] about a thousand dollars. This system of making mala prohibita into crimes is destroying all respect for the criminal law. What can we think, when we see men heavily fined, probably ruined, for doing that which is absolutely harmless in itself?

The act is aimed at the Chinese, and no search warrant is required to enable a police constable to enter the premises of a Chinaman whom he may suspect of smoking opium. Of course, this means plenty of [illegible] to the police, and the opium smoking will go on as before. I think these Australasian colonies had better beware lest they provoke the Chinese. I should not at all be surprised if in ten years' time a Chinese fleet, officered by Japanese, were to come down here and demand compensation for all the insults and wrongs inflicted on the Chinese.

The New Zealand Official Year Book for 1901 has been issued since I last wrote. It is an admirable compendium of statistics and other information on every subject connected with New Zealand; but we could spare some of the information to enable it to be issued earlier. It is never out until at least nine months of the following year have elapsed.

The birth rate for 1900 has very slightly increased from 25.12 per 1,000 in 1899 to 25.60 in 1900. It was 25.74 in 1898. It is still the lowest in the Australasian colonies.

The handbook goes on to say: "With a falling birth rate, the census taken in 1896 showed lower numbers of each sex living at the period under five years than at the next quinquennial period, which is unsatisfactory, indicating, as it does, that there are not now sufficient children living at the earlier years to maintain the number of those of some years now found in the tables. [illegible] That the fertility of women in New Zealand is decreasing, further facts will tend to show. Taking the number of married women in New Zealand at what may be considered the child-bearing ages (i.e., from fifteen to forty-five years inclusive), as shown by each census since 1878, and for the same years the number of legitimate births (excluding plurals) registered, the birth rate per 1,000 married women of the above-stated ages is easily found, and is shown to be steadily declining. In 1878 the rate was 337 per 1,000, and in 1896 it had fallen to 252; or, in other words, in 1878 one married woman of the ages specified in every three gave birth to a child, while in 1896 the rate was 1 in 4 only." The figures for each census year are given below, and are followed by a table showing the declining birth rate and the increase in the marriage rate in the United Kingdom.

BIRTH RATES (LEGITIMATE) PER 1,000 MARRIED WOMEN AT CHILD-BEARING AGES FOR EACH CENSUS YEAR, [illegible]

Year (Census)	Number of Married Women between 15 and 45 Years of Age	Number of Legitimate Births (Plurals excluded)	Birth Rate per 1,000 Married Women (from 15 to 45 Years of Age)
1878	[illegible]	[illegible]	[illegible]
1881	[illegible]	[illegible]	[illegible]
1886	[illegible]	[illegible]	290.1
1891	[illegible]	[illegible]	[illegible]
1896	[illegible]	[illegible]	252.1

Of course, this decrease is in by far the greater number of instances voluntary and intentional, but I am inclined to think that partial or complete sterility is increasing. Certainly a very large number of married women have only one or two children, and deny stoutly that they take any measures to restrict the number.

One thing that lessens the birth rate is the almost entire absence of a class of women who are common in Europe—those who work on the land, and who are generally very fertile. Our women almost invariably wear corsets and wear them too tight. This, producing uterine and ovarian diseases, causes sterility. Our young women are almost all more or less anæmic, and suffer from [illegible].

SALT DIET AND CANCER.

To the Editor of the Medical Record.

SIR: I notice in the January 18th number of the MEDICAL RECORD that Dr. [illegible] thinks salt a causation of cancer. Whether this is so or not, the fact that a man has ever been a whaler I now believe is sufficient reason for supposing him to be predisposed to cancer of stomach. Having seen several cases of carcinoma of the stomach in men that had been whalers in earlier years has often made me ask myself the question, Has the fat or salt diet anything to do with the etiology of the disease in these cases? N. B. ALDRICH, M.D.

FALL RIVER, MASS.

SANE OR INSANE.

To the Editor of the Medical Record.

Sir: No better case offers for the discussion of this much-mooted and debatable question than that of Czolgosz. The medical experts on this notable case sum up their opinions, according to the daily press, thus: "Czolgosz was in all respects a sane man, both legally and medically, and fully responsible for his acts." "There has been found absolutely no condition of any of the viscera that could have been at the bottom of any mental derangement. Taking all in all, the verdict must be socially diseased and perverted, but not mentally diseased." Accepting that to be the verdict of the competent alienist and pathologist, still it is an open question whether, from a strict scientific point of view, and not that of accepted precedent, it be correct? Even though present methods of the investigation of viscera, especially the central nervous organs, yield no pathognomonic conditions in such cases, and perhaps may never be developed to that wished for perfection, it is a most debatable question if molecular changes of a most subtle kind do not really exist, manifest only in the "insane" deportment of the individual. If a person's sanity is so "socially diseased and perverted" as to lead him to acts which, taken by themselves, must be called insane, shall it be said that he is "not mentally diseased," or that he "is in all respects a sane man?" With all due respect to learned authority, its position is a *conditio ad absurdum;* no person can be "socially diseased and perverted" and "not mentally diseased" at the same time. There is "a great gulf fixed" between the position of the alienist, and the social scientist. The one goes to precedent, to accepted definition, for his verdict, the other seeks the truth, the fact, as it is, utterly regardless of precedent. The one turns to the law, the other to the deportment of the individual as a social unit. Let us ignore the law and precedent, and following advice once given by Thomas Paine, "turn to the book of nature," to the individual, and think as if our own sanity were the question at issue. If we turn to precedent, to alienistic authority, we shall find no really definite ground to stand on. We must turn to nature. Now, what is the natural standard, the only ethical basis, of sanity? The natural or ethical standard of sanity is that the individual is at all times in that condition of mental equilibrium as to be master of his environment to that degree of being mentally equal to self-maintenance, without, at any time, losing or weakening his mental balance so as to threaten in any way his self-maintaining abilities. In other words, the environmental or individual ethical standard of to-day is that a person shall, at all times, possess such mental abilities as to render him self-supportingly useful to others, and at all times be so mentally self-controlled as in no way to weaken his self-supporting abilities by acts of his own, or even want of action, inability to make use of self-maintaining opportunities presented in existing social conditions, or environment. The standard of nature is the ability to survive in the environment one finds himself in. Can it be said that the man Czolgosz was ever in that ethically sane condition? The expert verdict, "socially diseased and perverted," is all-sufficient evidence that he was not. It is true that on this ethical basis—the only scientific basis to judge such a question by—the oft reported assertion that "all men are partially insane, more truly often temporarily insane, is justified.

Insanity, *per se*, is of an emotional nature, very often acute, frequently a more or less continuous perversion of the emotions. The sexual pervert in all its varied perversions is a fitting example. Insanity is an emotional perversion, or loss of control of the self-preserving faculties. Czolgosz is an example in *optima forma*. The prevailing social madness for mental perversion, emotional excitement to "drive dull cares away," is another. Alcoholism has the same basic foundation. Many deeds of so-called "heroism" are of the same form of acute emotional madness. Insanity invariably assumes some degree of mentality, intelligence. Total self-control in all directions, total loss of intellectual self-maintaining ability, is not lost. When that is lost, the person approaches or has entered upon imbecility. Imbecility, idiocy, is total loss of mental excitability. The idiot is without self-maintaining ability in any environment. The insane possesses some. When Czolgosz attacked the President, he was emotionally insane; he had temporarily lost all control of his self-preserving abilities. In another sense, and because others benefit thereby, the hero, who sacrifices his life to save another's, entirely forgets self, and from the natural ethical standpoint is in the same condition. The emotionally insane person who so loses control of his self-maintaining abilities as to be dangerous to the life or property of others, is in a criminal condition from the social standpoint, and must be so treated. The assassin, the incendiary, and often the thief, are emotionally mad, and under circumstances must be treated with that kind of justice meted out to mad dogs, in order to save the lives and properties of others. They may be as mentally irresponsible as the imbecile, and yet, because they seek to escape, to justify their deeds, they do show an equivalent degree of sanity. Czolgosz' emotional insanity went to that degree of perversity as to be on the danger line of mental imbecility, and for that reason, and in all such cases, merited the treatment received as a safeguard to others, and the general social equilibrium. These few remarks will suffice to introduce the discussion of the question "Sane or Insane" from the ethical, or strictly scientific, point of view, in contradistinction to the alienistic, or forensic, medical.

Sharon, Mass.

THE REPORT ON THE MORTON CURRENT.

To the Editor of the Medical Record:

Sir: My attention has been called to a report appearing on page 710 of your issue of November 2, 1902, in which it appears that I served on a committee of the Electro-Therapeutic Association to consider a question in controversy between Dr. A. D. Rockwell and Dr. W. J. Morton regarding certain currents obtained from the static machine.

Permit me to state that although originally appointed on this committee, I withdrew from service upon the same and had no connection with the report. The fact that I had the pleasure of being personally acquainted with one of the gentlemen, and not with the other, disqualified me from service. The retention of my name on the committee in the published report was doubtless an oversight.

A. E. Kennelly.

THE PRIVILEGES OF THE ACADEMY OF MEDICINE AND THE DUES QUESTION.

To the Editor of the Medical Record:

Sir: Although Dr. A. Jacobi speaks so slightingly of anonymity in his letter in the Medical Record of January 18, I must beg your leave to preserve mine, for reasons which will be appreciated. I have only a word to say in reply to the writer's strictures. In the first place, what is, is not always right, as Dr. Jacobi himself contends in the matter of what he calls the "Filipinoverbuchen," and if the by-laws of the Academy of Medicine prevail, the humiliation of publicity for delinquents, many of whom are so through misfortune and against their will, then it is time to amend the by-laws.

One can readily believe that the writer is correct in his observation that the prompt-paying members—those who are so prosperous as not to feel the spending of $20 in charity, or who get full value of their money in the sweets of office, delight at the multitude of outsiders. The managers of a dispensary are always pleased to see the waiting-room crowded with beneficiaries—it makes them feel so philanthropic. The talk about the honor of belonging to the Academy is absurd, for everybody knows how eagerly an applicant of the prescribed professional age, with a double eagle in his hand, is taken in. As for the rest, Dr. Jacobi advances no argument, but writes simply from the standpoint of a man of means with no sympathy for the self-respecting poor man, when he sneers at his less prosperous colleagues who cannot afford to pay $20 for an empty privilege, as fit only for "some money-making or money-shaving (*sic*) trade." If he himself has not striven all his life to get full money equivalent for services rendered the sick, then he is really different from (shall I say better, than?) his more humble professional brother, who must collect his bills or else let his Academy dues go by default.

A Mortified Listener.

LIBERTY AND THE SANATORIUM QUESTION.

To the Editor of the Medical Record

Dear Sir: In your issue of January 11th, over the signature of J. C. L. Whitcomb, M.D., appears a statement as follows: "Within the last four months an attempt was made to operate surreptitiously a sanitarium within the village limits. It was a sort of branch to an out-of-town hospital." . . . This statement is without foundation. There has been an attempt on the part of certain people to claim that the so-called sanitarium within the village limits was a branch of the Loomis Sanitarium. In the first place, it is doubtful whether the statement is correct that the village doctor under consideration attempted to run a sanitarium; but even allowing that he did, there never has been the most remote connection between his place and the Loomis Sanitarium.

Yours very truly, J. Edward Stubbert, M.D.,
Physician in Charge, Loomis Sanitarium.

PROLAPSE OF THE KIDNEY

To the Editor of the Medical Record:

Sir: In your issue of January [illegible], Dr. Mark I. Knapp, referring to my paper on "Some Points in the Diagnostic Palpation of Prolapsed Kidney," presented at the Genito-Urinary Section of the New York Academy of Medicine, says he does not see how I can diagnose prolapse of the kidney in the first and second degree with the patient in the erect position. I am accustomed to classify prolapse of the first and second degree as [illegible], and apply the term prolapse [illegible] to those cases where the upper pole has descended below the border of the ribs in front. I thought I made it clear that the lesser degrees of prolapse, though present, could be detected by grasping the right loin with the left hand [illegible] to be examined, the thumb in front, and depressing the fingers under the ribs when the patient inspires, the fingers of the same hand behind depressing the [illegible] at the same time, so as to narrow the space through which the kidney may escape. Thus, as the patient is made to take a deep inspiration, the kidney is driven down between the thumb in front and the fingers behind, and the degree of mobility is easily recognized. It is certainly easier to palpate the kidney when the patient is in the erect position than when she is on her back.

I quite agree with Dr. Knapp that prolapse of the kidney in the first or second degree seldom produces symptoms. The only treatment required is a well-fitting abdominal belt with pad, or a properly adjusted corset, to prevent or delay exaggeration of the degree of prolapse.

But prolapse of the kidney below the border of the ribs is quite a different thing. It does produce symptoms, though they are not always recognized. But if such a degree of malposition of so important an excretory organ as the kidney does not produce recognizable symptoms at the time it is observed, it should by no means be neglected. For the prolapsed kidney is always more or less congested in consequence of interference with its circulation and the discharge of the urine excreted through the urethra, and this must in time result in serious disease of the organ.

Those who can speak from experience must admit that any form of artificial support for prolapse of the third and fourth degrees is most inefficient and unsatisfactory, and, though it may for a time alleviate the symptoms, never results in a cure.

In view of the foregoing facts, then, and also that the technique of the operation for fixation of the kidney has been so perfected that the results are permanent, and that it involves no risk, I hold that every kidney prolapsed with its upper pole below the border of the ribs in front demands operation for its permanent fixation.

The operation is not so necessary to relieve the symptoms, which are often insignificant, but to obviate serious structural disease of the organ.

Augustin H. Goelet, M.D.

205 Broadway, New York.

THE GOOD OF PHTHISIOPHOBIA

To the Editor of the Medical Record:

Sir: Dr. S. A. Knopf's article on "Official and Private Phthisiophobia" shows him to be a man of practical clinical ability and great tenderness of heart; but, unfortunately, the problem of tuberculosis cannot be solved by giving the patient the benefit of the doubt, or by making him the prime object of attention. From the sociological standpoint, we cannot, with our present therapeutic attainments or expectations, make a very strong plea for institutions for the treatment of the tuberculous. On the other hand, we are justified in demanding any reasonable sacrifice and expense for establishing institutions whose special object shall be the protection of the nontuberculous part of the community. Secondarily, such institutions can be made to bear as strongly on the interests of the consumptive class as if this were the main reason for their establishment.

Now, there is just one way to obtain institutions for isolating and treating tuberculosis. Is that by appealing to the humanity of the public? By no means. You can touch in this way only the philanthropist and the voter who is tuberculous himself, or who has or recently has had tuberculosis in his family. Even then he will not vote to sustain such an institution unless you can convince him of the relative curability of the disease, and unless his own or his consumptive relative's sentiments are favorable to institutions. What is the best claim that can be made for the curability of recognizable consumption? Probably most medical men will agree with me that 25 per cent. is a liberal estimate, although [illegible] with reasonably favorable circumstances and habits. Of course, I have no regard to the pathology and prognosis that [illegible] is a little tuberculosis, but refer only to cases clinically recognizable. Go to the average citizen with the proposition to maintain sanatoria for the benefit of the tuberculous, with the prospect of curing one patient out of four, and what will be the result? He may not say it, but he will think about as follows: "This institution is going to cost a good deal and [illegible]. It isn't going to cure enough people to make much difference, and those that are cured [illegible] to the consumptive [illegible] and what will be the result? [illegible] without the sanatorium the chances for recovery are about [illegible] and that the [illegible] is 'human nature.'"

I fancy that the reader has been thinking that the sanatorium is practically an assured fact for New York State, but this was only because the [illegible] of the average citizen has been touched. Rightly or wrongly, the idea has become prevalent that tuberculosis is a disease which is contagious, and which has no source except in diseased human beings and certain animals. This phthisiophobia is the strength of all reform by public action in regard to the disease which kills more human beings than any other. Destroy phthisiophobia and you might as well abandon the fight. If it is absolutely impossible to prevent infection—or rather if the term infection applies to tuberculosis only in a theoretical sense, as Dr. Knopf and the school which he represents seem to believe—then let us drop all attempts at preventing tuberculosis except by personal hygiene. The people cannot understand fine discriminations, neither can that part of the profession which thinks as I do, and they must be dealt with consistently and without sentiment. If the people of the whole State vote for a sanatorium for consumptives, with the idea of limiting a specific infection, the people of the particular locality in which it is proposed to erect that sanatorium are bound to oppose it on account of the same argument, magnified by proximity. They can be appeased by showing them just what precautions will be taken against the development of local foci, but we cannot expect to secure sanatoria on the ground of the infectiousness of tuberculosis, and then disarm local opposition by explaining that it is not so very contagious after all.

As a matter of sentiment, I like to think of Dr. Knopf pleading against the United States Marine Hospital Service, for the admission of a poor consumptive foreigner. But from the standpoint of the issue involved, nothing could afford a worse precedent. The majority of our population now realize, whether they came here two hundred and eighty years or one year ago, that we have absolutely no selfish interest in immigration, unless the immigrant is far above the average human being in material wealth or intellect. We have population enough for all practical purposes, and, not to mention other reasons, the very basis of this discussion is the best possible reason for desiring to avoid overcrowding and for maintaining large tracts of land without permanent habitation. Setting aside purely personal and sentimental reasons, what earthly excuse can there be for admitting to this country an individual who is not only a source of disease, but who is almost inevitably destined to be dependent on some one and very probably on the public? Here is one of the most brilliant of the advocates of State assistance in regard to the problem of tuberculosis arguing by word and deed against the ultimate necessity of such assistance.

Again, Dr. Knopf argues for a national health board in the same breath in which he protests against the only institution which can perform such a function. Theoretically, I agree perfectly with Dr. Knopf in his condemnation of our State system. I would go further and deplore the fact that in America we have some forty-five legislatures, governments, sets of laws, and sets of politicians. I wish we might wipe State lines off the map, as was seriously proposed when our constitution was framed, but we can't do it. Our only possible hope of securing something like national unity in matters of public health is to support in every possible way the tendency to enlarge the scope and powers of the United States Marine Hospital Service. Even if we disagree with some of the regulations of this department—and some one will always disagree with any proposition—the future interests of the country demand that the medical profession shall uphold it until it is established on such a basis that dissent with certain of its expressions can be made without threatening the very existence of a national health board.

A. L. Benedict, M.D.

Buffalo, January [illegible], 1902.

Progress of Medical Science.

The Boston Medical and Surgical Journal, Jan. 23, 1902.

Notes on X-Light and Radio-Active Substances in Therapeutics.—William Rollins has made experiments with radio-active substances in the hope of finding a substitute for x-light. He found that some of the radiations retained their activity after passing through animal tissues as thick as the body of a guinea-pig. He is anxious to have radium tried on lupus, superficial cancer, and diseases of the skin in which x-light has been found useful. Radio-active substances can be used in sealed capsules held against the body by adhesive plaster, or they can be made to cover larger areas by mixing them with rubber or celluloid to form moisture-proof plasters. These plasters may be still further protected by being coated on the side nearest the body by aluminum foil, and on the opposite sides by lead foil. They could be kept in stock by the yard by druggists and given to patients by prescription with proper directions as to the length of application. They could be worn at night. They could be used by the poor at much less expense than sittings for the use of x-light from a vacuum tube.

Lymphatic and Portal Infections Following Appendicitis.—John C. Munro says that these infections, singly or combined, are not so rare as many would have us believe. He himself has previously reported fourteen cases, and now adds six more which establish the following conclusions: The degree of lymphatic infection is not dependent on the extent of the appendiceal inflammation, a mild chronic appendicitis at times giving rise to a severe lymphangitis. The lymphatic disturbance may date its origin from an appendicitis occurring many months beforehand. Persistent fever without any other evident cause should suggest one or both of these infections. Spasm, tenderness, and fulness (spasm of the quadratus lumborum) indicate a retroperitoneal infection, possibly due to appendicitis. Chills and hepatic tenderness, associated at times with jaundice, may be of appendiceal origin, and this origin, especially in obscure cases, should be sought for most carefully in physical examination, in the personal history, and, if necessary, in abdominal exploration. Prompt and thorough drainage of the liver, together with the removal of the inflamed appendix, offer the best means for recovery. Finally, abdominal section, with definite free exploration of all abscesses within reach, is far more satisfactory, not more difficult, and less dangerous than aspiration.

Journal of the American Medical Association, Jan. 25, 1902.

Blood Examination from the Standpoint of the General Practitioner.—F. W. Higgins makes a plea for a more thorough consideration of the clinical problems of blood conditions, and says that, while few general practitioners may hope to make any original discoveries, each one can follow out without great expense or so very elaborate apparatus many of the technical methods. He gives some of the formulæ used in staining preparations, etc., and describes some of the simpler procedures. He also adds certain statements to the significance of the more common blood findings.

Climatology of Arizona with Especial Reference to the Climatic Treatment of Pulmonary Tuberculosis.—C. F. Craig thus enumerates the peculiarities of the Arizona climate: (1) The temperature of Arizona is higher than in some regions of the Mississippi Valley, by an average of 15 to 20° in summer, and by 30 to 40° in winter. Yet the relative humidity is so low in summer that the sensible temperature is 5 to 10° lower in Arizona; that is, the sensibility of the human body to heat is really less in Arizona than in Illinois. The nights throughout the winter are apt to be cool enough for open wood fires and for blankets. Generally, overcoats are not needed during the day, even in midwinter; (2) The variations in altitude are very pronounced, and this is a striking advantage in some respects, as with the same general conditions as to temperature and dryness of air the physician is able to select nearly any altitude he may desire, ranging from sea level at Yuma to 6,800 feet at Flagstaff. The improvement in nutrition, particularly the great increase of red blood corpuscles, that sometimes occurs upon removal to a higher altitude is remarkable; but the intense expansion of the lungs in these cases is detrimental rather than otherwise. That an enlargement of the thorax follows a residence at a high altitude there is no question, but the increased resonance of the percussion note is generally due to an emphysema produced by the altitude rather than to increased lung power; (3) A low percentage of humidity is a most important essential in the elements that go to make up the ideal climate for the treatment of pulmonary tuberculosis. Other conditions being equal, tuberculous cases improve much more rapidly, and a greater percentage of recoveries is found where the relative humidity is lowest. The lack of moisture in the atmosphere, as reported by the United States Weather Bureau at Phœnix, is truly surprising. On several occasions during the month of June, 1900, the relative humidity fell as low as 1 per cent., as compared with 50 and 60 per cent. in Chicago, and Eastern cities. One especially noticeable effect of the dry air is the great diminution in the amount of sputum in those cases in which there is excessive bronchial catarrh accompanying the tubercular lesion; (4) The value of a maximum of sunshine can hardly be overestimated, as the relative humidity and the temperature depend to such a large extent upon it. Its mission cannot be fulfilled by the model comfortable house, and, as the love of sunshine is proverbial, its influence in inducing patients to live outdoors is perhaps greater than any other climatic feature.

Death from Chloroform Anæsthesia.—Bayard Holmes says that his anæsthetizers have been trained to give chloroform on two thicknesses of cheese-cloth held over the left index finger or spread on a wire mask. It is given drop by drop from a bottle with a notched cork. But in the case reported the anæsthetizer was a physician with whom the author had had no experience, and the operation was done under unfamiliar surroundings. There was no oxygen at hand. The patient was a woman of thirty-eight years. The presumptive diagnosis lay between (1) Extrauterine pregnancy and hemorrhage; (2) Tumor arising from the pelvis with twisted pedicle, or (3) Pregnancy with some complicating intrauterine hemorrhage. Abdominal section revealed a multilocular cyst of the left ovary, which was removed in the usual manner. The patient apparently stood the anæsthetic well. Operation required twenty minutes and no stimulants had been required. On account of the small amount of fluid in the peritoneal cavity, and on account of the slight contamination of the wound edges with the cyst contents, the abdomen was now washed out with warm normal salt solution. This much revived the patient, and she resisted and threw her body and legs about. This led the anæsthetizer to administer more chloroform, and she became quiet again. Suddenly it was noticed that she had stopped breathing. The operator left the care of the abdomen to an assistant and immediately opened the mouth, drew out the tongue and compressed the root of the tongue forward. The assistants elevated the foot of the table and artificial respiration was performed. This resuscitation was very tardily begun; the heart was beating and the blood became aerated. The abdomen was closed and artificial respiration was continued. There seemed to be occasional efforts at automatic respirations, but it was necessary to keep up the mechanical breathing. Dressings were applied and the patient removed to her room, placed crosswise of the bed on a stretcher, and artificial respiration kept up. Although the woman was in better position for this procedure, it became less and less effective. She became cyanotic, the heart stopped, and she died more than an hour after the first recognition of danger. There was no post-mortem examination. The heart continued to beat for three-quarters of an hour after all automatic respiration was suspended. The aeration of the blood was for a long time quite perfect, as shown by the red lips and disappearance of all signs of cyanosis. There is no evidence that the patient died of thrombosis, enzyme poisoning, or any other effect of the simple and rapid operation.

New York Medical Journal, January 25, 1902.

Curettage of the Puerperal Septic Uterus an Inexcusable Procedure.—W. R. Pryor notes that in curettage of the uterus, septic from streptococcic infection, the mortality rate is 22 per cent. He states that he has personally followed a certain method of treatment (already published) which has given no mortality either in his own hands or in those of the gentlemen who have adopted it, except in one class of patients, namely, those who had been curetted before coming under observation. There were ten such patients, three of whom died, a mortality of $33\frac{1}{3}$ per cent.; and the lesions remote from the pelvis and in the pelvis which were found at the time of operation were in these curetted cases far more general and of a more serious nature than in any others seen. In the light of such experience the author holds that curettage of the septic puerperal uterus is most mischievous. Such being the case, it is imperatively necessary that gentlemen who attend cases of puerperal fever should be able either from clinical symptoms, or, better still, from bacteriological examination, to determine what cases are septic and what cases are not septic; for if mistakes are made, valuable lives are lost.

Paratyphoid Fever.—S. J. Meltzer calls attention to a series of cases presenting the general features of typhoid fever, but negative as to the Widal test. On the other hand, the sera of these patients agglutinate promptly specific bacilli, which are isolated either from the blood or [illegible] These [illegible] belonging to the [illegible] groups are [illegible] by the [illegible] [illegible] from those [illegible] of this disease. They resemble those which occur in true typhoid fever. [illegible] It is very likely that the paratyphoid [illegible] [illegible] [illegible] Widal [illegible] [illegible] typhoid [illegible] (1) By [illegible] the blood [illegible] (2) By testing the blood of each patient with paratyphoid bacilli [illegible] from established cases of paratyphoid.

Transitional Displacement of Purulent Fluid of an Empyema by Saline Solution at the Time of Operation.—Dr. A. J. [illegible] describes a typical case of pleural empyema, in which he resected the seventh rib at the angle of the scapula [illegible] Simultaneously with the cutting away of the rib with the bone forceps, [illegible] entering the pleura, he introduced the glass nozzle of a fountain syringe containing saline solution at [illegible] F. [illegible] The moment the cavity was opened the solution was allowed in, with good pressure from a height of at least six feet. By no [illegible] of compression the too rapid expulsion was prevented; the saline solution gradually displaced the purulent effusion and he was enabled to flush the cavity out entirely without stopping, at the same time obviating the danger from hemorrhage, the saline solution doing away with the necessity of leaving part of the purulent fluid in; thus insuring a clean cavity from the start. A simple gauze drainage was applied and the saline solution by the aid of a gauze wick was gradually absorbed by capillary attraction. After the pus had been removed, the adhesions existing were broken down and the lungs expanded perfectly. On the second day after the lung had expanded the wick was removed and a small drainage tube put in its place. This was removed on the fourth day. The best part of the case was that a complete recovery took place in three weeks and four days, and the soldier returned to light duty. The only other treatment consisted in the syringing out with hydrogen peroxide, followed by the saline solution. A collodion seal was put on on the tenth day. In this connection the author notes that the degree of rapidity or retardation of the absorption of the saline solution is entirely in the hands of the operator. An oiled silk protective pad can be put next the skin.

Medical News, January 25, 1902.

A Case of Spontaneous Rupture of the Eyeball.—W. Whitehead Gilfillan reports a case of this kind in a woman of eighty-seven years. When first seen she had a slight catarrhal conjunctivitis of both eyes. Senile cataract in each eye was also observed. Nearly a year later she was seized with a severe pain on the left side of her head, which was followed by rupture of the eyeball. There had been a large hemorrhage from the globe of the left eye, the crystalline lens was lying on the left cheek, much vitreous humor had escaped, and a part of the iris was prolapsed. This is an unusual case from the fact that there was no traumatism, nor was there any ulcerative process of the cornea. There was no staphyloma. There was marked arteriosclerosis, and it is possible that straining at stool caused the rupture of one of the vessels of the eye, and so gave rise to the hemorrhage.

On the Use of the Opiates, Especially Morphine.—Oscar G. Young declares that for the relief of intense pain in any [illegible] under ordinary conditions there need be no hesitancy in giving a moderate dose of morphine hypodermically. Or it may be given by mouth or by [illegible]. Inflammations, especially of the serous membranes, are [illegible] benefited by its use. For excessive cough without increasing the number of râles, it is most useful. In cases of [illegible] and in ordinary [illegible] so-called, there is no greater relief obtainable than by hot internal and external applications and four or five 2-grain doses of Dover's powder, one every hour. Opiates are [illegible] in [illegible] diarrhea, diabetes mellitus, and in oversecretion of any part except the skin. In mucous diarrhea, after the intestinal canal has been cleansed by a purge, opiates may be used to check the diarrhea. Unless there are [illegible] effects from the drug after the first or second administration, ¼ to ½ of a grain can be given once a day or even twice for one or two weeks without hesitation. However, one injection every second or third day will often be sufficient. Morphine is chiefly eliminated by the stomach. For intense neuralgias there is nothing so powerful to relieve the

[illegible] a [illegible] can be used to [illegible] of [illegible]. [illegible] But these [illegible] effect be [illegible] by the administration of the [illegible] of [illegible] grain of [illegible]. The [illegible] The [illegible] of the [illegible]

What Reliance Can Be Placed upon the Image Produced by the x-Ray from a Medicolegal Standpoint?—[illegible] James [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] of accuracy that can be attained by no other method of diagnosis. The [illegible] It is within the discretion of the trial judge to admit in evidence an x-ray photograph, and [illegible] of whether it is a [illegible] appears to be representative of the object portrayed, and may be useful to the jury or not, rests in his discretion. The employment of this method should be [illegible] if it is [illegible]

Hemorrhagic Typhoid Fever, Report of a Case Ending in Recovery.—C. B. L[illegible] and J[illegible] [illegible], from their experience with the case which they report, believe that it is a question whether more than a very few of the many drugs which have been recommended for the hemorrhagic diathesis are of use in this condition. Oil of turpentine holds a [illegible] to control hemorrhage and to [illegible] in typhoid fever and in other hemorrhagic conditions. Calcium chloride favors more rapid coagulation. Gelatin is undoubtedly making for itself a place as a hemostatic. Decinormal salt solution may be called for in lowered blood pressure or to stimulate a flagging or weak heart. Whiskey, ammonia, or strychnine will generally suffice for a cardiac stimulant. Adrenalin chloride [illegible] is now demanding attention. [illegible] of [illegible] walls it would undoubtedly be of great service. The local use of astringent washes is often beneficial. Statistics seem to show that about two-thirds of the patients die.

A Rapid Method of Detecting Bacillus Coli Communis in Water.—B. H. Stone describes a method which requires only seventy-two hours to be sure of the presence of the organism, while specimens which do not contain gas-fermenting bacteria can be declared negative in twenty-four hours. (1) A Smith's tube filled with a 2 per cent. dextrose bouillon is inoculated with [illegible] of the water to be examined and grown twenty-four hours at [illegible] C. If no gas is formed, the absence of the colon bacillus is shown. (2) If from 25 per cent. to 70 per cent. of gas is formed in the closed arm, a tube containing [illegible] of neutral broth to which has been added 0.3 [illegible] [illegible] solution is inoculated with [illegible] c.c. of the contents of the Smith's tube, and grown twenty-four hours at [illegible] C. (3) A second Smith's tube is inoculated with 0.5 c.c. of the contents of 2 and grown twenty-four hours at [illegible] C. If there is no gas, it is certain that the gas producer in 1 was not the colon bacillus. If, on the other hand, gas is produced in this tube, it is reasonably certain that the bacillus coli communis is present. The gas formula may be ascertained from 3.

Philadelphia Medical Journal, January [illegible] 1902.

Remarks on Vaccination in Relation to Skin Diseases and Eruptions Following Vaccination.—Arthur Van Har[illegible] [illegible] that the [illegible] which have [illegible] employed the [illegible] have [illegible] to retain [illegible] keep in the [illegible] thus acting as a [illegible] for all pathogenic [illegible]. They have at present [illegible] fallen out of favor but have their place. As a [illegible] for the first few days [illegible] [illegible] the [illegible] has [illegible] the condition of the areola will [illegible] [illegible] rest [illegible] [illegible] should be applied. [illegible] proper way of treating a vaccination sore.

Gastroptosis and Gastric Motor Insufficiency.—J. [illegible] Steele, in speaking of the treatment of this condition, says that tight lacing and the hanging of heavy clothing from the waistband should be absolutely forbidden. [illegible] of the health corsets may be worn that do not constrict the waistband, and that have an arrangement by which the weight of the clothing is supported from the shoulders. After pregnancy or operations upon the abdomen [illegible] should not be worn too [illegible]. The manner of the patient's life should be carefully directed. Rest for at least an hour after meals, flat upon the back with the clothing loosened, is most useful. Large amounts of food should not be taken at one time. The food should be [illegible]

Any stated diet cannot well be given, but it must depend upon the amount of hydrochloric acid secreted, and upon the presence or absence of dilatation. A milk diet is not usually well borne. The patient should wear abdominal bandage.

A Case of Pneumococcic Arthritis Accompanying Acute Croupous Pneumonia.—D. J. Milton Miller reports the case of a laborer who was attacked by acute croupous pneumonia. The only infection outside of the lungs was a rather extensive pleurisy, which, however, was not attended with a demonstrable effusion. On the eleventh day of the pneumonia the right wrist became swollen and painful. Cultures from the joint fluid were taken later, and a pure culture of a lancet-shaped diplococcus was obtained, and in the water of condensation a few short chains were observed. The inflammation was confined to the single joint. The prognosis of this form of arthritis is grave, for the high mortality is well known. The wrist in this case at the last observation was still stiff and of little use, and the prospect of complete restoration of function seemed very doubtful. The treatment consisted in fixation upon a splint and the application of lead water and laudanum; later, massage and similar measures to restore the function of the joints were employed. In suppurative cases the treatment should be by incision, flushing, and drainage.

The Lancet, January 19, 1902.

Observations on the Nature and Treatment of Pernicious Anæmia.—A. McPhedran gives unhesitating adherence to the theory of gastroenteric toxæmia as the cause of this affection. As to treatment, the use of arsenic has been largely abandoned. The gastroenteric theory has suggested intestinal antiseptics, but those tried have not been found to offer any definite results. Decinormal saline solution has been used subcutaneously with benefit, but it is so painful that it cannot be continued. In other cases, antistreptococcus serum was of great value. McPhedran does not believe that at the present time we have any remedy acting with certainty for the cure of this malady.

Fibroma in the Male Breast.—A. Webb Jones reports the case. The patient, an Egyptian soldier, aged thirty-five years, came to hospital complaining of a gradually increasing swelling of the left breast which he first noticed four months previously. Latterly he had also been troubled with slight pain. On examination the left breast was uniformly enlarged to about twice the size of the right. The outline stood out in marked contrast to the opposite side, but retained its general shape. On palpation the mass felt soft and elastic, but no indication of lobulation—as in a lipoma—could be obtained. It was freely movable on the chest wall. The breast was removed without difficulty by Thomas' incision. Microscopically the growth proved to be a pure fibroma.

Ocular Pain; Its Significance, Varieties, and Treatment.—Percy Dunn says that generally speaking pain is an invaluable symptom. It teaches us many an important lesson and provides us with many a clue to treatment. This is especially the case in glaucoma and in iritis; so, also, to a great extent in ocular affections generally, except in diseases of the fundus of the eye which are not painful. Very little pain occurs in connection with conjunctival troubles. The cornea, on the other hand, is exquisitely sensitive, and the slightest irritation evokes great pain. Corneal lesions leading to photophobia give rise to pain, and in most of these cases we find blepharospasm due to a minute corneal ulcer. In these latter cases the patients should be encouraged to open their eyes voluntarily as far as possible. Locally, the eye should be cleansed twice a day with a 1-4000 chinosol solution, and atropine with cocaine be dropped in. Internally we should order arsenic and quinine. The pain of specific iritis calls for leeches to the temple, early use of atropine to prevent posterior synechiæ, and for the constitutional mercurials. For rheumatic iritis, nothing relieves the pain so quickly as the old-fashioned bran poultice. Pain in eyes which are atrophied may call for enucleation of the affected globe. The pain of glaucoma calls for iridectomy.

Note on the Blood Relationship of Man and the Anthropoid Apes.—Albert S. F. Grunbaum reminds us that the serum from an animal—*e. g.* a rabbit—which has been injected intraperitoneally several times with any given organic fluid will, if mixed in small quantity with a dilute solution of the fluid used for injection, produce a more or less marked precipitate. To such a serum has been given the name "anti-serum." Hence, the serum from a rabbit that has been treated in this way with human blood which gives a precipitate with human blood may be, although somewhat paradoxically, called "human anti-serum." Adopting the general mode of application of the test, the author finds that "human anti-serum" gives a precipitate with three species of anthropoid apes, and to him this precipitate is practically indistinguishable from that obtained with human blood either in quality or quantity. Occasionally it has seemed that the blood of the orang gave a more gelatinous precipitate as compared with the granular precipitate of the other bloods, but this may have been due to accidental circumstances. The granular precipitates from other bloods are also liable to become sticky when shaken up. But it is not only by the action of "human anti-serum" on anthropoid blood that this close relationship of the various bloods may be demonstrated. He has prepared gorilla, orang, and chimpanzee anti-serum. Tested in the way described they all react, not only with their own blood, but with each of the others, and also with human blood. Here again, in the absence of definite standards, he is unable to assert that there is any difference of reaction among the many combinations of anti-serum and blood which can be made with the four above-mentioned bloods and sera. He has not noticed any record of a microscopical application of this test applied in the same way as in serum diagnosis. By this method, using one drop of 1-per-cent. blood solution with one drop of anti-serum, a result is produced reminding one very much of the clumping of bacteria, and in this way, too, it is possible to differentiate human and anthropoid blood, because there is an earlier and more complete reaction when the anti-serum is used on its own blood.

British Medical Journal, January 18, 1902.

Two Cases in Which the Activity of Phthisis Was Excited by Operations for Local Tuberculosis.—A. J. Rodocanachi reports these cases. The first was that of a man aged forty years, with extensive disease of the metatarso-phalangeal joint. This was operated on, and the cough which he had had became much worse, and he died in less than a month. The second case was that of a man aged twenty-two years. Suppurating inguinal glands were excised, and the patient grew rapidly worse, dying in less than a month. The patients were poor, and could not go away for any change, and a refusal to operate would have condemned them to a lingering death in either a poor cottage or a city workhouse. So the operation was risked in the hope of benefiting the patients.

The Relation of Glaucoma to Thrombosis of the Retinal Veins, with Notes of Cases.—E. Harries Jones quotes several cases in which glaucoma occurred as a sequel to unilateral thrombosis of the central retinal vein, associated with arteriosclerosis, but without albuminuric retinitis. In three of the cases the glaucoma was acute, and followed the retinal condition in about six weeks. In the fourth case, the glaucoma was chronic, and did not occur until nine months after the retinal vessels were affected. In two of the cases, glaucoma occurred also in the eye unaffected with thrombosis. The clinical significance of this complication in cases of thrombosis naturally lies chiefly in the direction of prognosis, which is really not bad in many cases of simple thrombosis, as, after the circulation is established again and the hemorrhages are absorbed, the patients often retain some useful vision.

Observations on the Surgical Treatment of Obstructive Jaundice from an Experience of Over 200 Cases.—A. W. Mayo Robson declares that the treatment of this affection depends upon the diagnosis. If the diagnosis is doubtful an exploratory operation is advisable, providing the general condition of the patient renders it probable that such a procedure *per se*, apart from what is to follow, will not hasten death. If malignant disease is positively diagosed, operation can, with some few exceptions when it is possible to remove it completely, do little good, or, at the best, can probably prolong life for only a short time. If a diagnosis is made of gall-stones, common duct cholelithiasis, chronic pancreatitis, simple stricture of the common bile duct, inflammatory adhesions causing pressure on, or stenosis of, the hepatic or of the common bile-ducts, or hydatid disease of the liver pressing on or discharging into the bile-ducts, operation is decidedly advisable if the patient is at all in a condition to bear it.

A Possible Predisposing Cause of Cancer.—Harold Mason from his investigations concerning the cause of cancer has collected some valuable statistics: Out of 175 houses, deducting one in which two cases occurred, 117 are upwards of thirty years old and fifty-seven are less than thirty years old; *i. e.* 67 per cent. of these cases occurred in the older houses. All these observations seem to point to the conclusion that whatever the ultimate cause may be cancer will be found to be due to some germ, whose habitat is a sewage-contaminated subsoil, and that it gains entrance to the organism through one of the mucous membrane-lined apertures in the body. This would account for various facts which have been noted in the study of this disease: That the cancer death rate has increased during the last sixty years—a time synchronous with the development and extension of the water closet system of drainage, the first style of which was simple unglazed drain pipes laid end to end, sometimes joined with clay and sometimes not. That the infection of the alimentary system is as high as 88 per cent. That people over forty years old are more subject to it. That females are more subject to it than males. That cancerous houses in the [illegible] are found often [illegible] houses. That a large proportion of these cancer houses are old houses [illegible]. That the older houses are more apt to become cancerous than the newer ones. That the houses which are built on a porous subsoil are more likely to become cancerous than those built on clay.

Deutsche medicinische Wochenschrift, January 6, 1902.

Formation of Anti-Bodies Against the Bacteriolytic Immune Bodies of Cholera.—R. Pfeiffer and E. Friedberger, in experimenting with anti-cholera serum, have convinced themselves that, under certain circumstances, anti-bodies against the bacteriolytic immune bodies of anti-cholera serum are formed, although according to Ehrlich's theory the formation of anti-immune bodies is very improbable. They took old anti-cholera goat serum and inoculated it into rabbits. The serum of these rabbits was then mixed with fresh anti-cholera goat serum, which had a marked bacteriolytic action, and it was found that such bacteriolytic action was entirely destroyed. This phenomenon can be explained in three ways: (1) In the anti-immune serum there were present anti-complements which nullified the action of the complements in the anti-cholera goat serum. (2) In the anti-immune serum there were present anti-complements, which owed their origin to the presence of complementoids present in the old anti-cholera goat serum used, and thus indirectly acted upon the complements of the fresh anti-cholera goat serum. (3) The action was due to the presence of anti-immune bodies produced by the inoculation of the old anti-cholera goat serum. Pfeiffer and Friedberger think that in our present knowledge the last view is the most tenable. In regard to cholera-immune bodies two questions are of interest: (1) Are the cholera-immune bodies of different species of animals identical? (2) Are such immune bodies, present in normal and specific goat serum, identical? The first question is to be answered in the negative, the second in the affirmative.

Blood Examinations in Pulmonary Tuberculosis.—L. Appelbaum considers the blood changes which occur in pulmonary tuberculosis in the various stages of the disease. In the first stage cases may be divided into two groups: First, those persons who have shown a marked predisposition to tuberculosis and who possess the characteristic cachectic appearances, and second, those in whom such is absent, and in spite of the tuberculous lesions the general condition has remained good. In the first class of cases there is present hæmoglobinæmia, a reduction in the number of erythrocytes and leucocytes, together with a decrease in the specific gravity. These changes are principally brought about by the poor nutritive conditions present. In the second class of cases, the blood condition does not perceptibly vary from normal. In the second stage of tuberculosis, the blood condition in the first class of cases above mentioned shows apparent improvement; the amount of hæmoglobin, the number of red blood cells and leucocytes, and the specific gravity are all increased. At first thought it seems paradoxical that, with the increase in the severity of the disease, the condition of the blood should show improvement. It is certain, however, that this improvement is merely apparent, and in reality means only that a marked concentration of the blood has taken place, thus giving the increase in the constituents mentioned above. This concentration is brought about by many factors, prominent among which are night sweats, diarrhœa, and fever. In the third stage of the disease all the constituents of the blood, with the exception of the leucocytes, are markedly decreased. The leucocytes are considerably increased in number, usually from 15,000 to 20,000 being present. The peculiar characteristic of this leucocytosis is the percentage increase in the polynuclear neutrophiles. They often constitute from 84 to 85 per cent. of the total number of leucocytes.

Münchener medicinische Wochenschrift, January 7, 1902.

Treatment of Melæna Neonatorum by the Subcutaneous Injections of Gelatin.—Dr. [illegible] reports five cases of melæna neonatorum which were successfully treated by subcutaneous injections of gelatin. As the mortality from this disease when treated by other methods is about 50 per cent., these results are very gratifying. Fifteen cubic centimeters of a warm 2-per-cent. gelatin solution were used in each case. In only one case was a second injection necessary. As a rule the quantity injected was divided into two portions, which were separately inoculated into the anterior thoracic wall or under surface of the thigh. Great care must be taken that the gelatin solution employed is absolutely sterile, and the inoculations must be carried out under all possible antiseptic precautions.

Silk Tendons.—Fritz Lange reports fifty-one cases as illustrative of a new method of tendon transplantation and the utilization of artificial silk tendons. The tendon of the muscle to be employed is divided, and if it is not long enough to reach the desired place for insertion, unto the free end a strong silk ligature is attached. The extremity of this ligature is inserted as desired. In order that satisfactory results may be obtained from the use of this method it is essential, first, that the artificial tendon be of a length sufficient to give the employed muscle its normal degree of tension; and second, that the operation be conducted under antiseptic precautions so that primary union shall take place. Observation has shown that in time the silk threads are completely surrounded by a layer of connective tissue and thus practically converted into a normal tendon. By this means the author has been enabled to correct many paralytic deformities even after marked contraction had taken place.

Hæmolysis.—Max Matthes undertakes to throw some light upon the point of contention between Ehrlich and Bordet as to whether the immune body prepares the red blood cells for the action of the complement or whether it unites with the latter before the erythrocyte is attacked. In order to settle this question in some measure, it is necessary to decide whether or not the immune body destroys the life of the red blood cell. It has been established that active pancreatic extract only digests red blood cells which are dead, and that it has no effect upon them so long as they remain alive. By the application of this principle the author shows that the immune body does not in any way reduce the vitality of the erythrocyte. The supposition, therefore, that it prepares this cell for the action of the complement is not well founded. Another interesting fact ascertained was that Hayem's solution when added to red blood cells, acts as an immune body, and when the complement subsequently is added, hæmolysis promptly occurs.

French Journals.

Syphilitic Chancre of the Lower Eyelid in a Little Girl of Six Years.—Lagrange describes the patient who, when she was first seen, was supposed to have purulent ophthalmia, but the development of enlarged submaxillary and preauricular glands with the presence of mucous plaques in the mouth determined the diagnosis. The pathogeny of this very rare affection cannot be determined in this particular case.—*Gazette Hebdomadaire des Sciences Médicales*, January 12, 1902.

Maladies of European Children in Hot Countries.—Crombie compares the mortality of children in England and European children in India in the year 1899. It stands as 15.31 to 1000 in England to 41.09 in India. The difference is 26 in every 1000. Diarrhœa is more frequent and severe in India. Enteritis is twice as frequent and severe in India. The mortality from dysentery is 9.8 to 100 in India. Pneumonia is more frequent in India. Abscess of the liver is unknown in children. In twenty-six years in India the writer has not seen one case of abscess.—*Gazette Hebdomadaire de Médecine et Chirurgie*, January 12, 1902.

Compression of the Umbilical Cord.—Maygrier states that there are cases of compression of the cord, the cause of which may be definitely determined, and also other cases in which the cause remains doubtful or indeed unknown. In general this accident can be avoided by carefully keeping watch of the infant's condition. It is not so easy during pregnancy to guard against, but in labor the constant use of the stethoscope will surely give timely warning. If the fetal heart sounds become feeble for any length of time, or if compression of the cord is only suspected, intervention to rapidly terminate the labor should be instituted at once for the sake of the child's life.—*La Médecine Moderne*, January 8, 1902.

Two Cases of Restoration of the Nose for Hypertrophic Acne.—Baudon describes these two interesting cases. The first patient was an Italian workman, whose nose was so deformed by this tumor that he had to raise the whole mass when he ate, as it hung so far down on his lip that it offered an obstruction to the introduction of food. The tumor was very soft, jelly-like in consistence. It was composed of two large lobes, separated by a central groove, while there were smaller lobes besides. The patient was anæsthetized and the operation performed by means of the thermocautery. There was no bleeding. There were various cavities filled with sebaceous material with friable walls. Within three or four weeks after the operation the wound was healed. The result was excellent. The second case was operated on in the same manner, only on account of a weak heart no anæsthetic was given. The writer prefers the cautery to the knife, as the operation with the former is bloodless. The operation, whatever the method, is easy, without danger, and productive of excellent results. The cautery should not be too hot; then hemorrhage and inflammation of the fat which forms such a large part of the tumor will be avoided.—*Archives Provinciales de Chirurgie*, December 1, 1901.

Laryngeal Syphilis.—Desplates relates his observation of a case of this nature. The patient, a woman, had suffered from aphonia for several months, had coughed for ten or fifteen years, was much emaciated, was partly deaf, and also showed ocular troubles, chief of which was a unilateral ptosis. It seemed to be a case of tuberculosis in the last stages. This diagnosis had already been made in a special throat clinic, which the patient had attended for a year. On the second examination, the writer found nothing in the lungs upon percussion, and almost nothing on auscultation. He made out cicatricial lesions on the epiglottis and on the aryepiglottic folds; the vocal cords were destroyed by large ulcerations that were on the way to cicatrization; the ventricles were a little affected. The trouble was evidently syphilis and not tuberculosis. There were no other lesions apparent, except those of the larynx. Radioscopy also confirmed the absence of tuberculous lesions of the lungs. Mixed treatment was instituted. At the end of three weeks the ptosis had disappeared, the eye had almost completely recovered its power of motion, pain had stopped, and the general condition was very good. It seemed unfortunate that the correct diagnosis could not have been made sooner, for the vocal cords can not be restored, and there is danger of stenosis of the larynx.—*Journal des Sciences Médicales de Lille*, January 11, 1902.

Annals of Surgery, January, 1902.

Mechanical versus Suture Methods for Intestinal Approximation.—J. Frank offers the following conclusions: (1) With no other method can be obtained all the excellent qualities in such an ingenious combination as with the mechanical devices of the Murphy type; (2) None of the suture methods can show such a low mortality; (3) The perfect holding together of the intestinal ends throughout their entire circumference with the button or coupler, obviating the danger of leakage, has been demonstrated by von Chlumski, who subjected all methods to the hydraulic-pressure test, and demonstrated the inferiority of the suture methods; (4) For end-to-end approximation, the button and coupler are the only devices that will achieve their greatest triumph, for it is in this operation that the suture methods yield the largest mortality.

The Cause of "Stitch Abscesses" and Their Prevention.—A. E. Maylard discusses the elements of septic infection under the circumstances suggested by the title of his paper, and makes a plea for the disinfection of the skin by mercury, according to the following method: (1) Cleanse the skin in the usual way by soap and water (turpentine and alcohol, or ether, if necessary); (2) Anoint freely and widely with hydrated lanoline-oleate of mercury (20 per cent.) and rub in; besmear a piece of lint with the same and leave on until a second inunction is performed twelve hours later. Every case should be treated for at least twenty-four hours before operation; preferably forty-eight hours should be given, with at least two separate periods of "rubbing in" for about ten minutes on each occasion; (3) On the operating table the piece of lint is removed, and the superfluous ointment rubbed off with a piece of sterilized gauze. The part is now ready for operation.

Intussusception of Meckel's Diverticulum.—The patient of J. M. Wainwright was a boy of seventeen years with abdominal symptoms calling for exploratory laparotomy. No tumor was made out, but there was great tenderness all over the lower zone of the abdomen with considerable pain. On opening the peritoneum there was a gush of about eight ounces of clear serum. The small intestine immediately presented in the wound. It was distended and showed a very marked general injection of its peritoneal coat. The sigmoid colon was then found to be collapsed and the cæcum sought. This was also collapsed with the appendix normal. The terminal collapsed ileum was then caught and followed up, and an intussusception about three inches long was found about three feet from the ileo-cæcal valve. There were as yet no adhesions, and the invagination was easily reduced by pressure on the apex. When the lumen of the bowel was restored, it was found that there was in addition a diverticulum, which was itself inverted. It was not until this moment that the true condition was known. This diverticulum, the inverted apex of which had evidently formed the apex of the intussusception, in its turn was easily reduced and found to be about one inch long and somewhat less in diameter. The diverticulum was clamped and cut away, and the wound in the intestine closed with silk Lembert sutures. The abdominal wall was sewed without drainage. Recovery was rapid and uneventful. Flatus was passed freely the night of the operation, and the bowels moved without cathartics the second day. Microscopical examination of the removed diverticulum showed a complete investment of both muscle layers, even at the tip, but otherwise was not noteworthy. That the case was one of a true omphalo-mesenteric remnant was proved by the presence of its muscular coat, as well as by its situation at the circumference of the gut opposite from the mesentery and by its distance from the cæcum.

Bristol Medico-Chirurgical Journal, December, 1901.

The Quiet Production of Anæsthesia.—J. Freeman considers this question along the usual lines. So far as the initial steps are concerned, he says that in his experience asking the patient to take deep breaths is a frequent source of trouble. It at once prevents any imitation of natural sleep, and it often produces reflex holding of the breath or coughing, because a vapor which can be breathed readily with quiet respiration may not be inhaled so well if deep breaths are taken. Imagine, however, a case where these troubles have not arisen, but the patient goes on rapidly taking deep breaths. Now this forced breathing is hard work; and besides that, in a minute or two a condition of apnœa is produced. For these two reasons the patient takes a rest, which is to a great extent a physiological one. A practical anæsthetist is able to see that this is not at all like respiratory failure from paralysis of the center; but the beginner, thinking the patient has "stopped breathing," commences shouting to him to go on breathing, slaps his face, or may even apply tongue forceps. Any rough treatment of this kind with a patient only partly unconscious should be carefully avoided, as it is frequently followed by alarming symptoms.

Some Surgical Aspects of Meckel's Diverticulum.—W. Sheen calls attention to the fact that the vitelline or omphalo-mesenteric duct usually becomes obliterated in the eighth week of fetal life, or a little earlier, and then disappears. It may persist under various aspects, the commonest of which is where its proximal end develops into a blind sac of gut some three inches long, attached to the ileum near its lower part, forming the ordinary Meckel's diverticulum, and usually giving no signs of its presence during life. Other lines of development or partial failure of involution may give rise to conditions of both clinical and pathological interest, and examples occur with sufficient frequency scattered through surgical literature to make the subject appear worthy of summary and comment. Closely associated with the duct, and producing various phenomena as a consequence of their persistence, are the omphalo-mesenteric vessels. Experience has shown that these cases may be divided into seven classes: (1) The common form of Meckel's diverticulum is a free tube of intestine, ending blindly, springing from the convex border of the ileum usually about three feet from the ileo-cæcal valve. It usually has no mesentery, and varies in length from three to ten inches. It may be strangulated in a hernial sac, may be ulcerated or perforated, may become knotted and produce strangulation; (2) The end of the diverticulum is connected with the posterior aspect of the umbilicus by a fibrous cord, which may be partially pervious. It may cause intestinal obstruction in various ways, the gut being thrown over it or drawn under it, or pushed through its mesentery—as in the case above detailed—or under certain conditions, especially much distention of the bowel, the diverticulum may drag upon it at its point of attachment, producing kinking; (3) The end of the diverticulum may be simply attached to the posterior surface of the umbilicus, giving the same series of conditions as in class two. (4) The most important class is that in which the diverticulum, having been continued for a variable distance into the cord, is pervious throughout at its separation. The mucous membrane at the umbilicus, prolapsing and proliferating, often forms a little polypus in the center of which is a minute channel through which fecal matter exudes; (5) There may be a large thick-walled, pear-shaped sac passing downward and backward, and adherent by a band of fibrous tissue to the small gut. In such a case the vitello-intestinal duct has become obliterated, and the remainder has become distended by secretion; (6) Closure of the process at its proximal and distal extremities will give rise to cysts in or behind the umbilicus; (7) The duct may exist as a fibrous cord from umbilicus to intestine. Illustrative cases are given under the foregoing headings.

The Edinburgh Medical Journal, January, 1902.

Treatment of Tuberculosis of the Bladder.—F. J. Freyer urges treatment of such a case on general principles, as if it were tubercle of the lungs or other organ. Cases are on record in which patients suffering from tubercle of the bladder have entirely recovered. Cod-liver oil, lime, strychnine, cacodylate of guaiacol and other tonics should be employed, together with a nutritious diet, and the patient should live in the open air as much as possible. As there is pus in the urine, urotropin will be administered in from 5 to 8 gr. doses three times daily, freely diluted with water. Salol and boric acid are also important drugs. Instillations of iodoform have not proved useful, and nitrate of silver is actually injurious in tubercular cystitis. Corrosive sublimate is the most efficacious drug for injections, and should be used in a 1 to 10,000 solution to begin with, gradually increased to 1 in 2,000. Morphine and belladonna suppositories should be given for relief of pain. As a final resource, cystotomy by the suprapubic route is recommended.

On the Treatment of Nervous Indigestion or Gastric Neurasthenia.—George Herschell says that the diagnosis of this condition is mainly to be made by a process of exclusion. We have the presence of indigestion in a patient who has evidently not gastritis, ulcer, myasthenia, nor cancer, but who just as evidently is a neurasthenic. In regard to treatment we must first make sure that the condition does not depend upon the absorption into the system of toxins from the alimentary tract. If by examination we can exclude myasthenia retention, we may give the frequent small meals which are best for neurasthenia. If HCl is in excess, we must give such food stuffs as combine with it, yet do not greatly stimulate its secretion, and these will be sweetbreads, calves' brains, oysters, egg albumen, and milk. We should give toasted bread and converted starch. For deficient HCl the author gives a dietary. For giving tone to the system, he recommends static electricity and the sinusoidal bath. The most valuable drug in the treatment of gastric neurasthenia he considers to be nitrate of silver given in ⅙ gr. doses in palatinoid form, diluted with a vegetable inert powder. It acts as an astringent, diminishes abnormal irritability of the nerves of the stomach, and is a tonic to the nervous system. The author gives in detail the local treatment, which may have to be applied to the interior of the stomach.

The Causation of Paralysis in Diphtheria.—Alexander C. R. Foulerton concludes from his experimental observations that in some cases of diphtheritic paralysis a descending affection of the neuron occurs, commencing in the portion lying in the motor ganglia, and it is not unlikely that the peripheral affection in these cases is not so much caused by the action of the toxin itself as by nutritive changes following on the lesion of the central portion of the neuron. On the other hand, in the common palate paralysis of diphtheria, for instance, there is distinct evidence of a peripheral affection, the muscles paralyzed being those in connection with peripheral nerve fibers, which come into close relation with the seat of toxin formation in the throat and naso-pharynx. In other words, the concentrated action of the toxins at the seat of their formation may, in some cases, be sufficiently powerful to affect the peripheral segment of the neuron, whereas, in cases in which the paralysis is obviously caused by the action of diluted toxin circulating in the blood, as in paralysis of the lower limb muscles, we conclude that the more susceptible ganglion cell may be affected by a degree of toxæmia which is not always sufficient to set up a primary change in the peripheral nerves. With the affection of the motor cells a descending lesion, due to nutritive disturbance, occurs, and so we get the peripheral neuritis at a later stage.

Archives of Pediatrics, January, 1902.

Sun Play-Rooms on City Roofs.—W. P. Northrup describes sun play-rooms which he has had some of his patients construct for delicate children or those suffering from incipient tuberculosis. The roofs of the houses in New York, or sometimes the roofs of tenements, can be utilized in this way, and give fine air free from dust and removed from the noise, confusion, and dangers of the street. These rooms are chiefly heated by the sun, but on cold days can be warmed by a gas stove. Their usefulness is beyond dispute, and in case of needed nervous isolation would be additionally useful in providing a place where the patients might be treated through any of the contagious diseases without contact with others.

The Malnutrition of Tuberculosis.—Floyd M. Crandall says that wasting, anæmia and other evidences of malnutrition are constant accompaniments of tuberculosis. These symptoms may occur in infants long before local disease can be detected. In infants tuberculosis shows a special tendency to be disseminated or to spread itself in the deep tissues as the lymph nodes. In some cases fever follows the anæmia and wasting, and then local lesions appear, mainly in the lungs. In other cases tuberculosis in children begins with well-marked local manifestations, particularly pneumonia. Anæmia of tuberculosis is usually simple anæmia. A diagnosis of tuberculosis cannot be made alone from anæmia or malnutrition, but when persistent and increasing without known cause suggests it. Anæmia or malnutrition should receive prompt and active attention, for it increases the danger of tubercular invasion, common at that period of life.

University of Pennsylvania Medical Bulletin, January, 1902.

The Pathogenesis of Lacunar Keratosis of the Tonsil.—George B. Wood concludes from his study of the subject that the disease commonly called mycosis pharyngis leptothricia is a true keratosis of the epithelium lining the crypts of the tonsils. The leptothrix buccalis maxima, the bacillus buccalis maximus, and other organisms do not possess any etiological importance, but are present simply as saprophytes. The disease is probably the result of a moderate degree of inflammation of the parenchyma of the tonsil causing an increased growth of the normal epithelium of the crypts.

A Review of the Literature of Ovarian Transplantation.—William R. Nicholson states in conclusion of his review that transplantation of the ovaries either homo- or heteroplastically is possible and that pregnancy will follow in a small proportion of cases. Furthermore, there is without doubt an influence in the ovaries beyond the mere process of ovulation which is very important for the development of the genitalia and also for their conservation. Whether this is strictly an internal secretion or not, remains to be proved, but certainly many facts seem to point to this as the solution. There is some evidence that the influence of transplanted ovaries may be most beneficial in the prevention of degenerations of the genitalia. Finally, all the evidence adduced tends to strengthen the position held by the so-called conservative school that the whole ovary, or if that be impossible, at least a portion of it, should be left in all operations in which such conservation will not tend to subject the patient to a greatly increased danger.

Observations of the Nature and Diagnosis of Acute or Infective Endocarditis.—Aloysius O. J. Kelly says that as this disease is rarely, if ever, a primary disorder, it is important to search for the possible source of infection. He gives the differential diagnosis from septicæmia, acute tuberculosis, typhoid fever, malaria, etc. He emphasizes the diagnostic importance of leukocytosis, of the results of bacteriological examination of the blood, and of a peculiar arhythmia or instability of the heart. The leukocytosis may not be marked, but will be a polymorphonuclear leukocytosis. The blood to be examined bacteriologically must be drawn from a small vein under strict aseptic precautions, and allowed to flow over the surface of agar or blood-serum slants and placed in an incubator at 37° C. Pyogenic organisms have often been found in the blood in many cases of sepsis of obscure origin. The arhythmia of the heart manifests itself by the sudden developing and almost equally sudden ceasing of extreme rapidity of the heart's action.

The Penetration Power of Formaldehyde through Various Substances.—Saverio Bufnanni found (a) that the dried vapor of formaldehyde, 20 grams per cubic meter, applied for twenty-four hours, does not sterilize the spores of anthrax. (b) Their destruction can be accomplished by means of 8 grams combined with 92 c.c. of water vapor to the cubic meter, for twenty-four hours. (c) Moist formaldehyde vapor in the quantity mentioned penetrates through ordinary cotton textures up to a thickness of 1.37 mm., linen 0.63 mm., wool 1.18 mm., and silk 0.16 mm., destroying anthrax spores beneath. (d) Formaldehyde vapor, up to 20 grams, with 182 c.c. aqueous vapor to the cubic meter, and for twenty-four hours, does not penetrate through dry paper, even though it be as thin as 0.06 mm. (e) Moist formaldehyde vapor, in the same amount and under the same conditions, penetrates moistened paper, and through writing paper (0.06 mm.) and some other varieties of paper it sterilizes spores placed underneath.—*Annali di Medicina Navale.*

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Ninety-sixth Annual Meeting, held in Albany, N. Y., January 28, 29, and 30, 1902.

HENRY L. ELSNER, M.D., OF SYRACUSE, PRESIDENT.

FIRST DAY—TUESDAY, JANUARY 28.

THE meeting was held in the Common Council Chamber of the City Hall, and was called to order at 10 A.M. by the President, Dr. Henry L. Elsner, of Syracuse, who then delivered the inaugural address.

Inaugural Address.—Dr. ELSNER briefly sketched the work of the year, and in so doing pointed out the danger of accepting unreservedly the views propounded by Koch. In this connection the speaker said that had these views emanated from lesser light than Koch they would have received little attention. He recommended that the society, as a body, should insist upon keeping up the effort to secure a good, wholesome milk supply. The president also recommended that the president-elect and the secretary be empowered to take such steps as would further the establishment of a national bureau of health. The speaker also declared that the profession in this State demanded the abolition of the delegate system of the State Society.

Proposed Union of the Medical Profession of the State.—Dr. ELSNER called attention to the fact that the American Medical Association had been practically reorganized on a broad and liberal basis. The old disagreement on a point of ethics, he said, had become a dead issue because of changed conditions and a more liberal spirit of the profession. The unification of the profession was demanded, not only by the profession, but by the thinking public. A reconciliation must and could be accomplished with dignity and without sacrifice of principles. The time had come for a final effort to gather the profession of this State under a single banner and upon a liberal platform which would secure representation in the American Medical Association. The Medical Society of the County of New York had taken the initiative by resolving to appoint a committee on conference, provided the New York County Medical Association did the same. It was found, however, that the latter body could not act in such a matter independently of the State Association, although it formally expressed itself as heartily in favor of bringing about a union of the medical profession in the State. The president recommended that the Medical Society of the State of New York appoint a committee of five, to confer with an equal number representing the New York State Medical Association, such committee to confer regarding the formulation of a plan which would unite the two State medical organizations into a body which should have representation in the American Medical Association. This committee should report at the next meeting of the State Society, and it should be understood that, in the event of a failure to bring about such reunion, the committee of the State Society should have the power to send delegates to represent that body in the American Medical Association.

Committee on Hygiene.—Dr. HENRY R. HOPKINS of Buffalo, chairman of this committee, presented a report in which he called attention to the prevalence of typhoid and smallpox, and the notable work done in the investigation of the relation of mosquitos to malaria. The meagerness of the salary of the State Commissioner of Health, as compared with the remuneration of the commissioners of game and fisheries and the State architect, was commented upon, and the folly of such a penurious policy pointed out.

Committee on Legislation.—Dr. FRANK VAN FLEET of New York presented the report of this committee. He said that no laws seriously affecting the medical law had been enacted during the last session of the Legislature. During that session 379 bills had received the attention of the committee.

The Osteopathy Bill.—On motion of Dr. VAN FLEET, the Society adopted resolutions protesting against the passage of the osteopathy bill. The chief reasons presented were: (1) That osteopathy is now legal in the State of New York in the hands of licensed practitioners, and requires no regulation; (2) That the class of people calling themselves osteopaths seek, not the right to introduce a new method of treating disease, but the right to treat disease without complying with the laws regulating all other practitioners, and (3) That the medical laws of the State are enacted for the protection of the community, and should apply to all practitioners or to none.

State Board of Medical Examiners.—Dr. M. J. LEWI of New York presented this report. He said 749 candidates had applied for license, and 150, or 20 per cent., had been rejected. There had appeared before the board of the State Society 671 candidates, of whom 139, or 20.7 per cent., had been rejected; the Homœopathic Board had examined fifty-eight and rejected six, or 10.3 per cent., and the Eclectic Board had examined twenty candidates and rejected five, or 25 per cent. Up to the present time, 6,349 candidates had appeared before the State Examiners, and 1,379, or 21.7 per cent., had been rejected.

Goitre; Its Medical and Surgical Treatment.—Dr. M. J. LEWI of New York presented this paper. He said that he had treated forty-seven cases of goitre. In the use of electricity, whatever success was achieved was in the parenchymatous, hemorrhagic, and exophthalmic forms of goitre. Iodine, applied externally in the form of the tincture, was comparatively useless, and if employed at all it should be internally. Much could be said both for and against parenchymatous injections of iodine. In many instances, death had followed such injections. In no case should such an injection be given until the part had been rendered surgically clean. After the injection, the site of the puncture should be immediately painted with iodoform collodion. His results had been more satisfactory with a mixture composed of equal parts of tincture of iodine and a 5-per-cent. solution of carbolic acid. From ten to thirty minims of this mixture should be injected once a week, each time in a different place. There was much less pain after the injection of this mixture than where iodine alone was used. Galvano-puncture was useful in parenchymatous goitres, but in the cystic form both electricity and drugs were useless. Such cases should be treated surgically, and in this connection it was reassuring to recall the fact that Professor Kocher had operated upon 2,000 cases, many of them exophthalmic or malignant, with only 1 per cent. mortality. The chief surgical procedures included ligature of the thyroid arteries, division or resection of the thyroid isthmus, and partial or complete excision. Professor Kocher employed local anæsthesia in all cases. This was advantageous because the patient was apt to suffer from dyspnœa during the operation, and if by chance the recurrent laryngeal nerve were included in the literature, the change in the patient's voice would indicate to the surgeon what had happened Another advantage was the absence of nausea and vomiting which in such cases might interfere with the healing process.

What Shall Be Done with the Professional Midwife?—Dr. M. J. LEWI of New York read this paper. As an indication of the extent to which midwives practise, the records of the health department of New York City were quoted. These showed that in the past year out of 80,735 births reported, 42,253 were by physicians and 38,482 by midwives. The author recounted the well-known abuses incident to the custom of allowing ignorant midwives to practise, and advocated such legislation as would exclude ignorant women from acting as midwives.

Dr. SIMMERMAN of Amsterdam, Drs. FRONZIAC and LUCIEN F. HOWE of Buffalo, Dr. A. JACOBI of New York, and Dr. Henry of Kings County discussed the paper and were practically in harmony with the views expressed in it. On motion, the Committee on Legislation was requested to draft a bill for the Legislature in accordance with the views expressed.

Human Asymmetry.—Dr. W. S. Ely of Rochester was the author of this suggestive paper. He called attention to asymmetry of the testicles and the veins of the scrotum, to asymmetry of the pelvis, to inequalities of the lower extremities, as shown by both longitudinal and circular measurements, and to many evidences of asymmetry in other parts of the body. The feet, he said, were never symmetrical by nature, and these asymmetries were intensified by the bootmaker. Most of us had our best eye or our best ear, and many persons would admit that when fatigued one leg leads and the other lags. The lungs were certainly far from being symmetrical, and were comparatively rarely involved in the same disease process. The heart itself was far from symmetrical, and the kidneys might be said to be never symmetrical. As no two individuals were alike and the two sides of the body were not identical, doubts arose in making deductions from the results of physical examination. Again, symptom asymmetry was a common mark of neurological conditions.

Dr. Henry R. Hopkins of Buffalo said that modern educators were urging the importance of child study—a subject which naturally came within the province of the physician—and therefore this paper was exceedingly timely and suggestive.

Dr. Lucien F. Howe of Buffalo said that he had had occasion to look up the literature with reference to asymmetries. He found that the left tear-duct was much more frequently diseased than the right, that deflections of the nostril were more often to the left, that the left lung was apt to be first involved in disease; that certain forms of degeneration were much more common on the left side; that the left lobe of the prostate was more often enlarged than the right—in short, and in a general way, that the left was the weaker side and the right was our "better half."

Dr. Carlos F. MacDonald said that this paper was in striking contrast with the views held by that modern school of scientific dreamers who were always seeking for signs of degeneracy as an excuse for the acts of criminals. He would venture to say that a perfectly symmetrical brain did not exist, and that marked asymmetry was observed in persons of the highest character and greatest mental attainments.

A Case of Sarcoma of the Tonsil.—Dr. Arthur G. Root of Albany reported this case. The patient was a male of twenty-three, in whom the whole of the tonsil was involved in a sarcoma. The only procedure available was lateral pharyngotomy, and it was successfully performed on January 17. Most of the cases reported had been in persons forty years of age, or older.

Dr. R. H. M. Dawbarn of New York spoke of his work in the line of complete double extirpation of the external carotid and all its branches for malignant growths in the region supplied by this artery. His experience comprised about forty of these operations, and other surgeons had done the operation about an equal number of times. He hoped this would be considered a sufficient warrant for his urging the more general trial of this method.

Dr. N. Jacobson of Syracuse said that two years ago he had presented to the Central New York Medical Association a patient upon whom he had, five months previously, performed lateral pharyngotomy for a very large sarcoma of the tonsil. Recurrence did not take place for eighteen months, and then it was in a part of the larynx which made a second operation impossible. He had reported also a case of epithelioma of the tonsil, in which he had removed the growth twelve years ago, and there had been no recurrence.

Dr. A. Jacobi said that he knew of one case in which a sarcoma of the tonsil had been removed ten years ago, and the man was still in perfect health.

The Treatment of Pelvic Suppuration.—Dr. Charles P. Noble of Philadelphia, Pa., was the author of this paper. It was based upon 200 cases of pelvic suppuration in women. In fifty-five cases treated prior to 1895 by the surgical methods then in vogue, the mortality was 16.3 per cent., whereas, since 1895, in ninety-one cases, the mortality was only 6.5 per cent. If fifty-four cases treated by incision and drainage were added, the mortality would be reduced to 4.8 per cent. Most of the latter cases were treated by incision through the vault of the vagina; in a few the incision was in the groin, and in a few others both incisions were employed. Incision and drainage should be the operation of election in puerperal cases.

The Sideroscope.—Dr. Thomas R. Pooley of New York exhibited this instrument, the purpose of which is to demonstrate the presence of particles of steel and iron in the eye. Dr. Pooley claimed to be the first to employ the magnetic needle for the purpose of determining the presence of such bodies in the eye. In June, [illegible], Dr. Pooley said he had read before the Section on Ophthalmology of the American Medical Association a paper on this topic. His attention had been directed to this method by his brother, the late Dr. James H. Pooley, but it was found that the underlying principle was not new. The instrument exhibited was an improvement on his own devised by Hirschberg. A glass tube has a magnet suspended within it by a very fine fiber of silk. In front of this and attached to the magnet is a concave mirror. The reflex of this mirror is thrown upon a graduated scale, and a deviation from zero points to the presence of a fragment of iron or steel. The eye must be brought as closely as possible to the glass tube in which the magnet is inclosed.

Gonorrhœa of the Prostate.—Dr. John Vander Poel of New York read this paper, which will appear in a future issue.

Fractures of the Nose.—Dr. John O. Roe of Rochester read this paper. He said that replacement of the fragments should be effected as early as possible. This was best done by the introduction of a smooth and slightly flattened sound, aided by the finger externally. He made use of a splint of aluminum or copper molded to the nose, covering its whole extent and resting on the superior maxilla. It is held in place by a strip of adhesive plaster. To prevent undue irritation, it was well to place adhesive plaster on the nose underneath the splint. In simple cases he used for the internal support a spring covered with rubber. In the more complicated cases it was sometimes necessary to pack the interior of the nose with gauze or cotton for three or four days. Before the introduction of any support the interior of the nose should be thoroughly cleansed, and then anæsthetized with cocaine or eucain. The dressing, if properly applied, would be painless; the only discomfort should be that arising from the cutting off of nasal respiration.

Dr. Leonard Weber of New York described two cases of severe compound fracture of the nose, successfully treated by the internal support obtained by the insertion of two large rubber tubes in the nose.

Dr. Wendell C. Phillips of New York said that those having the care of children should be impressed with the importance of attending immediately to even apparently slight injuries of the nose.

Dr. Roe, in closing, expressed his belief that the internal support was merely an accessory to the external support, the latter being of the first importance.

The Constitutional State Versus Catarrhal Deafness.—Dr. Sargent F. Snow of Syracuse presented this paper. He insisted that very little could be done if the skin were inactive, and that personal hygiene must be considered of paramount importance. Cold baths and frictions were exceedingly useful; they would so toughen the body surface that the latter would no longer constitute an ever-present menace to the internal organ. A torpid liver not infrequently thwarted all our best efforts to get medicaments through the Eustachian tube. It was Dr. W. C. Phillips who said that any one who undertook to treat the catarrhal diseases of the middle ear simply by the usual mechanical methods would surely fall far short of the possibilities of such treatment.

Dr. A. Jacobi said that middle-ear catarrh was very rarely primary, and hence local treatment of the nose and throat was almost everything in the treatment of disease of the ear. A most important prophylactic measure was the systematic daily washing out of children's noses. The iodides, when given for a long time in small doses, would certainly do away with a good deal of infiltration of the nose, throat, and ear. The ear should be treated principally through the nose and throat.

Dr. J. O. Roe said he believed nine-tenths of the cases of common "colds" arose from internal systemic derangements rather than from the influence of external causes, such as a cold draft.

The Educational Management of the Neurasthenic.—Dr. Edward B. Angell of Rochester was the author of this paper. He said that fatigue and exhaustion necessarily affect the higher mental faculties. The very weakness of the neurasthenic patient's volition made it easy for such a person to follow authoritative routine, and the physician should map out every detail of life for the whole twenty-four hours. By a carefully graded system of education or suggestion the neurasthenic could be most satisfactorily treated.

Dr. E. D. Fisher of New York said that as every chronic disease had its functional disturbance, where suggestion was carried on by wrong persons, such as Christian Scientists, a hold on the patient would naturally be secured because of the consequent improvement of the functional disorder.

Discoveries in Pathology.—Dr. Mary Dixon Jones of New York expressed in this paper some of her personal views concerning what is generally described as endothelioma, and also spoke of certain other pathological conditions which she claimed to have discovered.

A New Method of Bisecting the Uterus.—Dr. C. H. Richardson of Albany described the method. With the patient in the Trendelenburg posture, the uterus is separated from the rectum, brought well up, and one corner is then seized with forceps and drawn upon. An incision is then made into the median line of the uterus, through the body and the uterine cavity as well. With the fingers the adhesions of the tubes and ovaries are separated, and this is very easily done by following the lines of cleavage from below. The incision is then carried along the border of the broad ligament, and clamping the vessels as they are divided.

An Epidemic of Typhoid Fever in the Backwoods of Maine.—Dr. E. F. Brush of Mount Vernon described in great detail the conditions present in this region. The "fever" existed sixty miles up the river, and the boy who first became sick in the camp must have contracted the disease from picking up some of the flotsam. The interest of these cases was that they were so completely isolated. The family did not drink the water of the river, but the boy did swim in this river. His family used water from a barrel supplied from a brook which could not have become infected. The boy first taken sick drank from this barrel, and threw the water back. By this mouth contamination the other members of the family became infected.

A Case of Strangulated Hernia of the Left Ovary and Tube.—Dr. A. T. Bristow of Brooklyn reported this case. He said that he had been able to find about one hundred recorded cases. Congenital herniæ of the ovary were always accompanied by hernia of the tube. In very many of these cases other congenital defects exist, notably of the genital tract. The inguinal variety of ovarian hernia was the most common. In all cases of hernia of the ovary an operation was demanded. He had found the record of only one fatality after this operation. This low mortality, even in pre-antiseptic days, was probably to be explained by the fact that the operation was extraperitoneal.

Toxic Dosage in the Treatment of Some Nervous Diseases.—Dr. William C. Krauss of Buffalo read this paper. He said that failure in the treatment of many nervous disorders was dependent on the use of too small doses, even of appropriate remedies. The dose of bichloride of mercury, for example, was put down as from 1-20 to 1-10 of a grain, yet such doses would have no good effect in cases of brain syphilis. Such cases should receive hypodermic injections of one or two grains daily, and although these might cause toxic symptoms, gummata would be found to melt away quickly under their influence. Hypodermic administration was preferable in nervous disorders, and was less likely to cause excessive ptyalism. The usual dosage of Fowler's solution of arsenic was one to ten minims, yet in some cases of chorea he had given from thirty to sixty minims three times a day without causing toxic symptoms, and with an abortive effect upon the disease. He had not found the newer preparations of arsenic superior to the old ones. Nux vomica should be given in doses of 10 to 50 drops, after meals. In the treatment of neuralgic and neuritic disturbances he had found no other drug so satisfactory as nitroglycerin. The dose is rapidly increased until the pain ceases. The only unpleasant results from large doses were a throbbing headache, readily relieved by the bromides, and an increase in the size of varicose veins.

Dr. Henry R. Hopkins said that, *à propos* of large doses and vigorous treatment, he desired to say that for the past year he had adopted a plan of treatment for desperately severe cases of delirium tremens, which had been most successful. This consisted in removing at once from the patient one or two pints of blood, and at once transfusing double the quantity of normal salt solution. Under this treatment the mortality in these cases had been reduced from about 80 to less than 2 per cent.

Dr. A. Jacobi said that the doses used by Dr. Krauss were not "toxic," but simply large and effective. In cases of pneumonia, associated with cyanosis and dilatation of the right ventricle, he had obtained excellent results from giving 10 or 12 grains of good digitalis every three or four hours for several doses.

The Pathology of the Tissue Changes Caused by the Röntgen Rays.—Dr. Carl Beck of New York said that it might be assumed that, if in chronic inflammatory processes constriction of the vessels took place, the papillæ starve. A hair, extracted after prolonged irradiation, would be found altered in structure. Integumental specimens showed thickening of the tunica intima of the small blood vessels, a process tending to a narrowing of their caliber. Fibrous tissue was deposited in a reticular arrangement. The tunica muscularis and adventitia were affected in the same manner. The tissue change taking place in neoplasms was also of a similar type of chronic inflammation. The nutrition of their superficial strata was disturbed, the cells starved, and if over-irradiation were continued necrosis might result. It was easy, therefore, to understand the curative influence of the Röntgen rays on lupus, carcinoma, and sarcoma when confined to the integument. Reference was made to a case of lupus erythematosus in a woman of twenty-five, who was irradiated for twenty-five minutes every two days. It was not until the twentieth exposure that the redness decreased and some of the nodules began to shrink. Complete recovery was not expected for several weeks. In this work, it was well to have the vacuum tube as near to the diseased area as possible; it should certable not be more than four inches away, and might even be placed as near as two inches.

Glioma of the Retina.—Dr. Edward S. Peck of New York reported an interesting case of this kind coming under his observation, and briefly outlined the differential diagnosis.

The Position of the Eyes at Rest.—Dr. Lucien Howe of Buffalo presented a paper on this topic. He also exhibited a head-rest, in which exact fixation was secured by having the patient grasp a piece of soft wood with the teeth and indent it. This strip of wood was preserved as a record of that individual and by its aid the person could at another time be placed in exactly the position occupied at the first examination. Dr. Howe made the point that the way to find the position of the eye was to allow the light to come on to the macula of one eye and then to put some appliance, usually a prism, into position, that threw the image of the other eye off the macula. There then being no tendency to fusion, the eye swung into the position which it occupied with the greatest comfort.

Dr. Francis Valk of New York objected to this method because, as he understood it, the fusion power of the eye was eliminated. No method of testing, in his opinion, was worthy of confidence which did this.

The Civilized Indian; His Physical Characteristics, and Some of His Diseases.—Dr. A. D. Lake of Gowanda read a paper with this title. He said that the Iroquois Indians, before they felt the influence of civilization, were a type of perfect manhood and physical development, because they lived close to nature. They were now, on the contrary, extremely sensitive to changes of temperature, and were unable to do much work. Many of them die young, and if they reach the age of puberty, the women particularly show a high rate of mortality. They are very susceptible to tuberculosis, whole families often succumbing to this disease. Pneumonia is especially fatal, and if they recover they are apt subsequently to develop tuberculosis. Twenty years ago, the evidences of the former ravages of syphilis were often observed, but at the present time they are apparently immune to this disease. That there are abundant opportunities for venereal infection is shown by the prevalence of gonorrhœa. There is a steady increase in the diseases peculiar to women. There are about 1,800 Indians on the Cattaraugus reservation.

The Smallpox Problem.—Dr. Ernest Wende of Buffalo read this paper. He said that the first obstacle to prophylaxis was to be found in the lamentable ignorance of the masses regarding the measures necessary for the prevention of this disease. A constant menace to public health was the unreasonable and demagogic opposition of the antivaccinationists, who prate in season and out of season about the infringement of personal liberty. Health officers should be prepared for their work by a course of study in sanitation before being allowed to qualify for office. Instability and variations had characterized the present epidemic, and it was not to be wondered at that serious errors in diagnosis had occurred.

Symposium on Paresis.—A symposium on paresis was presented in the following papers:

Etiology.—Dr. Arthur W. Hurd of Buffalo opened the symposium with this paper. He said that probably a percentage of at least sixty had suffered from syphilis in former years, which was about ten times the percentage of syphilitics in other forms of insanity. Nine paretics had been inoculated with syphilis abroad, yet not one of them developed the disease. The records of one institution showed that only 3 per cent. of the priests admitted were paretics, and it was well known that syphilis was rarely found in this class of persons. Again, in the rural portions of Ireland, where syphilis was very rare, paresis was also rare. Four adult men were affected with paresis to one woman, while the disease was equally frequent in children of both sexes. This was to be explained by the fact that men have four times the opportunity of women for acquiring syphilis, while girls and boys have an equal chance of inheriting the disease. In his experience, paresis was one of the least transmissible of mental diseases. Paresis had been called the disease of the nineteenth century, yet if syphilis were the sole cause this disease should have been recognized and recorded much earlier. It was probable that the increasing mental stress, incident to the march of civilization, was an important factor. This theory found some support in the fact that the increase of the disease had been most rapid in those countries in which the national life had been the most strenuous. In a certain small proportion of cases mental stress might be the sole ascertainable cause, and in a still smaller number, traumatism might be the chief factor.

The Early Diagnosis.—Dr. Francis X. Dercum of Philadelphia, Pa., presented this paper. He said that early symptoms of paresis often resembled, though only superficially, those of neurasthenia. In the neurasthenic the symptoms were almost exclusively subjective, and he was anxious to describe his symptoms in minute detail. On the other hand, rarely did the paretic come to the physician of his own initiative, but he was usually brought by his relatives, who also are the ones to describe the symptoms. The neurasthenic was usually at his worst in the morning and at his best in the evening. In the paretic the reverse was the rule; he was apt to be somnolent toward night, and to exhibit defects of speech and mental action which were hardly noticeable earlier in the day. The paretic early exhibited evidences of fatigue, and a true impairment of memory and an indifference to everyday details of life were apt to be observed, together with certain occasional lapses in decorum. These symptoms served sharply to differentiate paresis from neurasthenia. When physical signs appeared, both neurasthenia and melancholia would be set aside. Changes in the reflexes, tremors of the tongue, and speech disturbances might be present, but their order of appearance varied greatly. The physical sign of the most importance was the peculiar manner of the paretic—the slight and almost infinitesimal changes in the facial expression and gestures, which showed that the patient was not in close touch with his surroundings. It was during the initial period—the neurasthenoid stage—that the diagnosis should be made.

Comparative Frequency.—Dr. Charles G. Wagner of Binghamton discussed this topic. He said that paresis had been recognized for about eighty years. Dr. Bell of the McLean Asylum in this country stated that while he had seen many cases of paresis abroad, he had not met with it in this country up to 1840, although on the lookout for it. During the last half of the nineteenth century 18,843 insane persons had been admitted to the Utica hospital for the insane, of whom 865, or 4.5 per cent., were cases of paresis. The proportion of women to men was 1 to 7½. In thirty years there were admitted to the Hudson River State Hospital 10,434 persons, of whom 672, or 6.4 per cent., were paretics. According to the reports of the Lunacy Commission, there had been admitted into all the hospitals for insane of the State a grand total of 49,7[illegible]7 persons, of whom 3,307, or 6.6 per cent., were cases of paresis. All the walks in life were represented. The records of one of the divisions of the Manhattan State Hospital show that in 1,300 cases the average duration of the disease was 15¾ months. They also show a remarkable preponderance of the disease among native Americans in an institution in which more than two-thirds of the inmates were of foreign birth. From the same source it was learned that paresis rarely occurred before the age of twenty or after the age of sixty. General paresis constitutes about 8.75 per cent. of all cases of insanity. The disease was gradually increasing in frequency.

Treatment of Paresis; Its Limitations and Expectations.—Dr. Edward Cowles of Boston, Mass., was the author of this, the last paper of the series. Tonics, a generous diet, and the interdiction of alcohol were well recognized elements in the treatment. Hydrotherapy was often beneficial. Hospital experience was opposed to the use of anti-syphilitic treatment in cases of general paresis, except when active syphilis was present. The limitations of treatment were suggested by the lack of a rational basis for our therapeutics in this disease. The modern conception of the intervening factor between syphitis and paresis was a grave nutritional disorder of the nature of a toxæmia.

SECOND DAY—WEDNESDAY, JANUARY 29.

Prize Essay.—Dr. A. Jacobi reported that the committee on prize essay recommended that the prize be awarded to Dr. Lucien Howe of Buffalo, the author of an essay entitled "A Study of the Connective Tissue of the Orbit by a New Method."

Ringworm; a Note on Its Treatment.—Dr. George Thomas Jackson of New York presented a brief communication on this topic. (See page 164.)

Dr. Baum of Syracuse said that he had tested this method for a long time, and now used it almost to the exclusion of all others.

A Case of Epilepsy, with Possible Medico-Legal Complications.—Dr. Frederick Sefton of Auburn presented this report. The patient was a candidate for admission to a college secret society, who was savagely tortured during the ceremony of initiation. He was taken home unconscious, but shortly afterward was apparently as well as ever. Months afterward he suddenly became morose and irritable, and without any reason shot a his sister, but fortunately missed her. In his flight from the house he fell collapsed, and was taken home unconscious. On awakening the following morning, he had no recollection whatever of what had happened, and to this day was skeptical when told of the occurrences of that night. Shortly before coming under the observation of the speaker he had taken Paris green, apparently with suicidal intent, though on his recovery he averred that he had no recollection of the act, and had no desire to die. On Dr. Sefton's recommendation he secured a position as purser on a ship, and still occupied that position, having had no further convulsions. The case was reported chiefly because of its medico-legal interest, and the ease with which testimony could have been obtained to prove the man's responsibility for his acts. The lesson to be learned was the need for such change in the taking of medical expert as would make it partake less of an *ex parte* character.

Dr. William Browning of Brooklyn said that while undoubtedly fright was occasionally an efficient cause of epilepsy, but in all the cases of this kind with which he was familiar the epilepsy had developed within a few hours or days. When the interval was very much longer, as in the case just reported, he would doubt very much whether the fright had had any material effect in producing the epilepsy. In these cases of psychic epilepsy, the patient does not usually do violence to others except when in some way disturbed or interfered with.

Report of the Committee on the President's Address.—The committee recommended: (1) That the question of holding a semi-annual meeting this year, and subsequently, be left to the judgment of the president-elect and the comitia minora; (2) That the question of a separate examination in internal medicine, to be held by the State Board of Medical Examiners, be referred to the Regents; (3) That the questions involved in Koch's paper regarding the communicability of bovine tuberculosis should be looked upon as inviting still further experimentation in this field before conclusions could be drawn, which would warrant any modification of existing methods of dealing with the disease; (4) That the various health boards of the State imitate, as far as possible, the work of the Milk Commission of the Medical Society of the County of New York; (5) That the Society favor the establishment of a national board of health, with representation in the President's Cabinet. After careful consideration of the recommendation to appoint a committee for conference with the New York State Medical Association, the committee gave it its unqualified approval, and suggested that the gentleman, from whom the recommendation had emanated, be made the chairman of the committee, and that he be empowered to associate with himself four representative members of the society. These recommendations of the committee were unanimously adopted without debate.

Nominations to the State Board of Medical Examiners.—For vacancies in the current year: Dr. A. Walter Suiter of Herkimer and Dr. George R. Fowler of Brooklyn; Alternates, Dr. James Spencer of Watertown and Dr. H. A. Fairbairn of Brooklyn.

Acute Lymphatic Pseudoleukæmia, with Report of a Case and Autopsy.—Dr. John L. Heffron of Syracuse discussed this subject. He said that although since 1832 this disease had been known as Hodgkin's disease, there was still a lack of agreement regarding its pathology. He agreed with Sternberg in the belief that it is a lymphatic tuberculosis, and the case he reported afforded an additional confirmation of this view.

The Changes of the Leucocytes in Disease as an Aid to Diagnosis and Prognosis.—Dr. Thomas R. Brown of Baltimore was the author of this communication. He considered the normal number of leucocytes to be 6,500 to the cubic millimeter. Physiological leucocytosis, the speaker said, was met with during the digestion of food—in pregnancy in primiparæ, in the new-born, and after violent exercise. The blood should never be examined for leucocytes during digestion, but in the fasting condition. The leucocyte count had been found most useful in such acute infectious diseases as typhoid, malaria, tuberculosis, influenza, whooping-cough, measles, scarlet fever, diphtheria, and pneumonia. Leucocytosis in typhoid fever pointed at once to some complication, often a perforation. In diphtheria, according to Engel, a high percentage of myelocytes was a very bad sign. The absence of leucocytosis in an uncomplicated tuberculosis was of value in differentiating it from other diseases; its presence pointed at once to a secondary infection with pyogenic organisms—a matter of much importance in cases of bone tuberculosis. A mild leucocytosis after ether anæsthesia was of special interest to the surgeon. A marked leucocytosis was sometimes observed after the administration of large doses of the coal-tar products, and it was probable that further study along this line would elicit information of value in connection with the diagnosis of secret drug habits. One could no longer doubt the very great value of eosinophilia as a diagnostic sign, even in sporadic cases of trichinosis. There was probably no surgical disease in which the leucocyte count was of more practical value than in appendicitis. It might be the only means of diagnosis in the fulminating cases.

An Unusual Case of Abscess of the Liver.—Dr. Edgar A. Vander Veer of Albany reported this case. The patient was a soldier who had had a severe attack of dysentery five months after reaching the Philippines. He returned to light duty in five weeks. He stated that about one-fourth of the men who were attacked with dysentery at the time this man was ill, developed abscess of the liver. This man continued to have many loose movements daily up to the time of his admission to the Albany County Hospital. At that time, physical examination suggested abscess of the liver, and on puncture three and one-half pints of a chocolate-colored pus were withdrawn. A rib was then resected and 1,000 c.c. more of this pus evacuated. The latter was examined at the Bender Laboratory, but no distinct microorganisms were detected. The patient's temperature fell after the operation, but the dysentery subsequently returned and was checked with great difficulty.

Gunshot Wounds of the Liver, with Report of a Case.—Dr. E. W. Mulligan of Rochester read this paper. He said that even as late as 1883 the prognosis for all but the slightest wounds of the liver was hopeless. Of ruptures, punctured wounds and tears of the liver, ruptures were the most dangerous. The case reported by Dr. Mulligan was that of an Italian male twenty-eight years of age, who, in a fit of despondency, had placed a revolver almost in contact with the abdomen, and shot himself through the liver. He was operated upon six and one-half hours later. The wound of entrance was clean, but the wound of exit from the liver was large, ragged, and was bleeding freely. The bullet had lodged in the muscles of the back. The hemorrhage was checked by packing in a large quantity of sterile gauze. The patient made a good recovery, leaving the hospital after about one month.

The Surgical Treatment of Peritoneal Tuberculosis.—Dr. John W. Whitbeck of Rochester reported in this paper two cases, one of which recovered. He left it still an open question as to whether or not light, air, and friction serve to kill the tubercle bacilli in cases of this kind subjected to operation.

Unusual Herniæ, with a Report of Complete Hernia of the Bladder, Complicating a Strangulated Hernia, Requiring Resection of the Bowel.—Dr. John B. Harvie of Troy presented this paper. He said that while many cases of hernia of the bladder had been reported, there were very few, if any, on record in which the whole bladder had been involved.

Dr. R. H. M. Dawbarn of New York reported a similar experience, in which his first impression, that the entire bladder had prolapsed, was only corrected by a rectal examination proving that the prostatic portion was still in its proper place. In view of the almost immovable attachments of the prostate, he felt that it was hardly possible for the whole bladder to become prolapsed into the scrotum. Careful examination in his own case had proved the large sac, which he had taken to be the bladder, was in reality a large diverticulum.

Dr. Harvie replied that in his case the fact, that the entire bladder was prolapsed, had been verified beyond any doubt.

President's Address. The Value to the Physician of Modern Methods of Diagnosis.—Dr. Henry L. Elsner of Syracuse delivered this address. He said that Leube's recommendation of the stomach tube in 1871 had cleared the way for accurate gastric diagnosis and scientific treatment. The diagnosis of cancer of the stomach should never be made solely upon the results of the tests for free hydrochloric acid. Henry's observation, that the reduction of the red blood corpuscles does not keep pace with the cachexia was also of great diagnostic value. The recognition of hyperacidity and hypersecretion, and the information obtained from inflation of the stomach were valuable additions to our knowledge. The benefit derived from the administration of the iodides in syphilitic disease of the stomach, and the intolerance to the iodides under ordinary circumstances, were diagnostic points too often overlooked. The speaker then dwelt upon the great value of the centrifuge to the general practitioner and the insurance examiner, as well as to the laboratory worker. Extended reference was made to the new science of hæmatology, and the assertion made that a positive diagnosis of the simplest form of anæmia could not be made without the data obtainable from blood examination. It was difficult at the present time to compute the gain to the profession from the ability to diagnose malaria and differentiate allied conditions by the presence of the plasmodium in the blood. Absence of leucocytosis, with the absence of other objective features, would often justify a diagnosis of typhoid before positive results could be obtained from the Widal reaction. On the other hand, a sudden and persistent leucocytosis in typhoid fever and certain other diseases often gave timely notice of some complication. The diagnosis of trichinosis had been corroborated by the presence of eosinophilia, and an eosinophilic increase might aid in the recognition of scarlet fever in doubtful cases. By improved technique the time required for making a blood examination no longer placed this method of investigation beyond the reach of the ordinary physician. The practical value of serum diagnosis had been exemplified during the Spanish-American War in connection with the differentiation of malaria, typhoid and dysentery. To show the application of this method to everyday work, Cabot was quoted as saying that the whole process could be easily carried out in the physician's office with less skill and labor than were required for the examination of urinary sediments. The speaker touched very lightly upon the use of the Röntgen rays in medicine, and appeared to "damn it with faint praise." The address concluded with the statements that "there is a feeling abroad which calls for thoroughness from those charged with the recognition and treatment of disease," and that "the moral force of scientific methods in medicine is the greatest factor in modern medical practice."

A New Symptom in the Diagnosis of Dystocia, Due to a Short Cord.—Dr. Samuel M. Brickner was the author of this paper. He said that hitherto the existence of a short cord had not been associated with any very definite symptomatology, but he thought he had succeeded in recognizing a characteristic symptom. This consisted in frequent urination in the intervals of the pains of the second stage, this being kept up until the fœtal head reached the vulva. During this stage the bladder became tightly pressed against the symphysis, and the urethra elongated. When the head receded, as occurred in cases of short cord, the bladder could readily empty itself; hence the explanation of this symptom was obvious. Two illustrative cases were reported, one a case of absolutely short cord, and the other a case in which the cord was twisted several times around the neck of the fœtus. It was interesting to note that when the pains succeeded one another very rapidly, there was no escape of urine from the bladder. It was now quite generally agreed that ten inches was the minimum length of the cord which would allow labor to go on without liability to certain accidents, such as rupture of the cord. Another very significant symptom was the marked and jerky recession of the head of the child with the cessation of each pain.

Dr. George Seymour of Utica recalled two cases of short cord, in one of which this frequent urination was present. In the other case, the woman had had no frequent desire to empty the bladder.

Dr. Brickner replied that the urine, in these cases, escaped entirely by reflex action, and without any desire on the part of the patient.

Symposium on Diseases of the Pancreas.—This symposium comprised the following papers:

Physiology of Pancreatic Diseases.—Professor R. H. Chittenden of New Haven, Conn., read the opening paper, taking the above as his theme. He said that we might well believe to-day that pancreatic digestion was not absolutely essential to the human economy. In 1848, Claude Bernard had begun his studies on the digestive properties of the pancreatic juice. The secretion of this juice was undoubtedly controlled by true secretory fibers, and these fibers were contained in both the vagus and the sympathetic. A study of experimental pancreatic diabetes led one to the belief that in the pancreas there were probably located certain specialized cells which manufacture an internal secretion, the latter exercising a special influence on certain metabolic processes in the body. There was a complete inability of the body to utilize sugar in the absence of the pancreas. When pieces of pancreas were well grafted, the entire pancreas could be extirpated without the occurrence of glycosuria. This glycosuria was not wholly due to increased transformation of the glycogen stored up in the liver. The blood of an animal from which the pancreas had been removed, showed no toxic substances, and when injected into another animal had no power to cause diabetes. Again, feeding raw pancreas did not check or prevent the usual symptoms dependent upon extirpation of the gland. To the physiological chemist the autointoxication theory of diabetes seemed especially attractive. There were indications that some forms of so-called pancreatic diabetes were to be explained, not through a simple disturbance of the pancreas, as from an injury, but by a physiological disturbance of the interrelation of several allied glands or structures.

Diagnosis of Diseases of the Pancreas.—Dr. W. S. Thayer of Baltimore discussed this topic. He said that in suppurative pancreatitis a tumor would be found situated deeply behind the stomach and colon, which is immovable. It was to be differentiated from a renal tumor mainly by its immobility and the fact that it does not extend into the flank. Its deep position could be revealed by inflating first the stomach and then the colon. In eight out of sixteen cases of diabetes coming to autopsy at the Johns Hopkins Hospital, Dr. Opie had detected pathological changes in the pancreas, chiefly a hyaline degeneration of the islands of Langerhans. Every case of disease or destruction of these islands had been found by this observer associated with glycosuria. In cases of acute pancreatitis there might be an increased quantity of fat in the stools. Interference with the digestion of albuminoids was suggestive though not characteristic of pancreatic disease. Acute pancreatitis was apt to occur in corpulent persons of middle age. It was associated with intense and agonizing epigastric pain in the median line, and the abdomen in this region would be found distended, rigid, and tender. The pain was, in some instances, augmented by pressure on the lower ribs, communicated through the spleen to the tail of the pancreas. The pulse was usually accelerated. Cyanosis might be a striking symptom. These symptoms were often associated with profound prostration, and were followed by collapse and death in four or five days. The symptoms might be ushered in with the symptoms of gallstone colic. In connection with the differential diagnosis, the possibility of mesenteric infarctions should be considered. It was rarely, if ever, possible to feel the pancreas in cases of pancreatitis, owing to the existing tenderness and the tenseness of the abdominal walls. In every case of severe epigastric pain with collapse, acute pancreatitis should be thought of. If it were possible to demonstrate the presence of a fat-splitting ferment in the urine, as had been claimed, we should have the first definite sign of pancreatitis. The diagnosis of chronic interstitial pancreatitis was rarely possible, though it was to be suspected, if occurring in connection with cirrhosis of the liver. The diagnosis of pancreatic calculi was hardly to be expected *intra vitam*, and could only be made when calculi were found in the stools. Cysts constituted the largest tumors of the pancreas. They were usually proliferating glandular cystomata. The smaller retention cysts were usually impalpable. These cystic tumors appeared as retroperitoneal growths extending well past the median line. They were to be differentiated mainly from cystic renal tumors, hydatid cysts of the liver and spleen, retroperitoneal sarcomata and large abdominal aneurysms. Secondary involvement, in cases of malignant disease of the pancreas, was rarely detected during life; out of ten cases of cancer of the pancreas occurring at the Johns Hopkins Hospital, in which a positive diagnosis had been made, either at operation or post mortem, in only three was a palpable tumor present. Acute pancreatitis should be recognized in many instances, and the importance of an early recognition of the cases going on to suppuration was obvious.

Surgery of the Pancreas.—Dr. Roswell Park of Buffalo discussed this subject. He said that the pancreas might be reached in various ways, viz.: (1) Through the gastrohepatic omentum above the stomach; (2) Through the gastrocolic omentum below the stomach; from the loin behind the peritoneum, and (4) Through the liver with the thermocautery. The danger of wounding important vessels and nerves, as well as the ducts of the gland, had had much to do with deterring the surgeon from interfering with the pancreas. In acute traumatism, the indications were to stop the bleeding, prevent the escape of the juice by suture, disinfect the cavity, and repair the injury. The route usually selected for attacking the pancreas from in front was through the gastrocolic omentum. If posterior drainage were amply provided, it probably would be desirable to close the peritoneum in front. The opening made through the omentum should be closed around the drain with sutures. Prolapse of the pancreas had been noted in a few cases. He had collected eight instances of this kind. For malignant tumor of the head of the pancreas, there was probably nothing to be done; but in abscess of the splenic end of the pancreas the removal of that portion of the pancreas should be practised. He had collected nine cases of removal of tumors of the pancreas, of which six had recovered. Acute pancreatitis was characterized, in individual cases, by fat necrosis, hemorrhage, suppuration, or total gangrene. There was some mysterious connection between pancreatic disease and hemorrhage. This tendency to bleeding was always intensified in the presence of jaundice. The treatment of acute pancreatitis was virtually that of peritonitis of the upper abdominal cavity, and consisted mainly in prompt drainage. Once the diagnosis was established, posterior drainage should preferably be made. If the pancreas were found necrotic, as much as possible of it should be removed. Posterior drainage was almost always necessary. Most cases of chronic pancreatitis were brought about by conditions having their origin in the biliary passages. The author closed his paper with an earnest appeal for early surgical intervention, applying the rule, "When in doubt, operate."

Pathology of Pancreatic Diseases.—Dr. George Blumer of Albany in this paper discussed only the more recent pathological work in this field. He said that the relation of the organ to the digestion of carbohydrates suggested that the pancreas possessed an internal secretion. When one-fourth or one-fifth of the gland was left intact, glycosuria did not occur. It was probable that in a certain proportion of the cases reported by the older writers the failure to discover disease of the pancreas was due to the fact that very little attention was given to the islands of Langerhans. It was now known that in many cases of diabetes the pancreas appeared normal, except for a hyaline degeneration of these islands. It had been shown that it was possible to cause pancreatitis by the introduction into the duct of irritants known to be present in the body. Pancreatic fat necrosis was formerly assumed to be the result of bacterial products, or of the presence of trypsin. The presence of microorganisms was not constant, and attempts to produce fat necrosis experimentally, by means of bacteria or their products, had been almost uniformly unsuccessful. It was now believed that the true cause of fat necrosis was the presence of the fat-splitting ferment, steapsin. The lesion consists in the splitting up of the fats into glycerin and fatty acids. Any pancreatic lesion which allowed of the escape of this fat-splitting ferment, might give rise to fat necrosis.

Clinical Indications for Surgical Interference in Acute Pancreatitis.—Dr. Joseph C. Bloodgood of Baltimore spoke on this topic. He said that in the first stage of pancreatitis, before abscess formation, little had been accomplished by operative interference, except a confirmation of the diagnosis. Most authorities now agreed that operative interference at this stage was contra-indicated. On the other hand, the onset of the abscess stage should be recognized early, for then operation was urgently demanded, and the successes were usually in [illegible] had given a history of one or more attacks, which could not be differentiated by the symptoms from the first stage of acute pancreatitis. He had traced eleven cases of acute pancreatitis that had recovered. Six out of the twenty-four operative cases recovered. Death occurred without operation in twenty-one cases of acute hemorrhagic pancreatitis. In the light of our present knowledge, delay seemed justifiable in the first stage of acute pancreatitis.

The Traumatisms of Pregnancy.—Dr. Denslow Lewis of Chicago read a paper with this title. He said that many years ago his attention had been directed to the subject by a physician's attempting to produce an abortion upon his wife by the introduction of a male silver catheter. The instrument suddenly slipped out of his grasp and disappeared. On examination, it could not be found, and it was only after abdominal section and evisceration that it was discovered lying up under the liver. The patient made a good recovery. The speaker reported other cases, such as the finding of glass rods, laminaria tents, and other foreign bodies in the abdominal cavity. In one case, a wooden spit, twelve inches long, remained in the uterus for two years. In two others, a knitting needle and a hair-pin were respectively forced through the navel in a desperate attempt to produce an abortion. Both mothers recovered. Many of these cases, even when the traumatism was severe, did well without interference. Dr. Lewis said he did not approve of the frantic efforts made by many physicians to remove the secundines after an abortion, for while no doubt these tended to cause infection, it was after all the infection itself that was to be feared. The entire uterine parenchyma had been torn out by manual interference. The speaker then went on to describe cases of severe falls in pregnant women, of knife wounds of the uterus, and of injuries self-inflicted in the effort to do a Cæsarian section.

Tendon Transplantation in the Treatment of Paralytic Deformities. Dr. Arthur W. Elting of Albany gave a sketch in this paper of the work previously done in this field, and commented upon the fact that this method had attracted more widespread attention abroad than in this country. Tendon transplantation was adapted for the following conditions: (1) Traumatic loss of muscles and tendons; (2) Spinal, infantile paralysis; (3) Spastic paralysis, Little's disease and hemiplegia, and (4) Congenital deformities, especially club foot. So long as there was evidence of spontaneous improvement, tendon transplantation should not be done. The simplest method of transplantation was by dividing the tendon of a healthy muscle and suturing to the tendon of the paralyzed muscle. The method of suture advocated by Goldthwaite was the one most generally employed. In his own cases of tendon transplantation the results had been very satisfactory.

Pneumogalactocele of the Breast, with an Unidentified Organism. [illegible] of New York reported this case. [illegible] All the physicians who saw the case agreed that the gas had been generated in the tumor and had not been injected. The creamy fluid contents of the tumor were also sent to a laboratory for examination. Bacteriological examination showed the presence of a [illegible] which could not be identified. Animal inoculations seemed to show that it was an unimportant, non-pathogenic organism. By incision, irrigation, and packing the galactocele was quickly cured, and another specimen of the fluid could not be obtained for examination.

A Simple Method for Determining the Percentage of Milk in Home Modifications. Dr. Rowland G. Freeman of New York said that there was nothing original about his method, but it had been made as simple as possible, and algebraic formulæ had been eliminated. The first thing was to decide upon the formula, the number of feedings, and the quantity to be given at each feeding. Then the proportion between the fats and proteids should be noted, and a cream should be selected containing the same proportion. The desired strength of cream could easily be obtained because, roughly speaking, gravity cream contains 16 per cent. of fat. Two parts of gravity cream, with one part of simple milk, containing 4 per cent. of fat, would yield a cream containing 12 per cent. of fat. With the formula, fat 3, sugar 6, proteids 1, the proportion between the proteids and fats is 1 to 3, hence 12 per cent. cream was needed for this formula, the required dilution being made with water. The quantity of sugar required for the whole twenty-four hours' supply should be calculated and this quantity put up in packages by the druggist.

Puerperal Hemorrhage.—Dr. George Seymour of Utica presented this paper. He spoke of the causes of antepartum hemorrhage, such as excessive cohabitation, criminal or accidental abortions, ectopic pregnancy, hæmatometra and abnormal implantation of the placenta. Cases of postpartum hemorrhage, caused by placenta prævia, inversion of the uterus, or by fibroids, might severely test the powers of even a skilled obstetrician. Recently Cæsarian section had been ably advocated as a means of treating placenta prævia. If it could be done as safely for the mother as podalic version, and with a reasonable assurance of saving the life of the child also, it would be a distinct improvement upon the present treatment.

Malignant Tumors of the Periphery; Their Pathology and Treatment.—Dr. Thomas H. Manley of New York gave a brief description of a variety of tumors, but owing to lack of time, read only a portion of his paper.

THIRD DAY—THURSDAY, JANUARY 30.

Officers Elected.—*President*, Dr. Henry R. Hopkins, Buffalo; *Vice-President*, Dr. William A. Moore, Binghamton; *Secretary*, Dr. F. C. Curtis, Albany; *Treasurer*, Dr. O. D. Ball, Albany.

A Unique Case of Double Dacryo-Adenitis.—Dr. D. H. Wiesner of New York reported this case. The chief features of interest were the picture presented, the activity of the disease, the treatment, and the complete recovery. He said that while most writers advised hot fomentations, he had made use, in this case, of ice cloths continuously, and recovery had taken place without breaking down or suppuration of the glands.

The Treatment of Pneumonia.—Dr. Reynold W. Wilcox of New York was the author of this paper. He said that the fact had been lost sight of that, while salicylic acid was itself an antiseptic, this was not true of any of the salicylates. We had in the treatment by creosote a fairly good means of combating the toxæmia, and by its aid the mortality in private practice should reach only 3 or 4 per cent.

Obesity of Adolescence.—Dr. Heinrich Stern of New York read this paper. He said there were two different forms of obesity during the adolescent period, one disappearing at the approach of maturity, the other continuing after the individual had attained full development. This circumstance seemed to be of etiological importance. The cases of obesity subsiding after maturity he designated as "transitory" or "specific," those continuing as "metabolic" cases of obesity. The metabolic as well as the transitory variety occurred in both sexes. The former was more frequent among boys, the latter among girls. Metabolic obesity of adolescence was a juvenile modification of what Dr. Stern had described as metabolic, or common, obesity. By this was meant a condition in which polysarcia concurred with a normal or slightly subnormal degree of body density. There was little doubt that transitory obesity of adolescence was caused by certain anomalies appearing at puberty, and declining at or before maturity. Such conditions might also prevail at the time of the menopause or after castration, in both sexes. The frequent occurrence of this form of obesity in girls was due to the more pronounced changes occurring in the female at puberty. The catabolic disorders were caused by faulty thyroid or parathyroid activity. Both forms of juvenile obesity demanded treatment only when the surplus weight was very excessive, and when complications were present; uncomplicated cases should not be treated, as the youthful organism was always weakened by it; the treatment in the advanced instances of metabolic obesity should mainly be a dietetic one. Thyroid medication and physical treatment in any of its branches might avail much in the therapy of the transitory obesity of adolescence.

Observations on Broken Necks.—Dr. Reginald H. Sayre of New York presented a number of photographs from cases of fracture of the cervical vertebræ. In making the diagnosis the position of the head was of extreme importance; if the fracture involved the three upper vertebræ, the head would be almost invariably twisted to one side after the manner of torticollis, there was often also an abnormal straightness of the back of the neck. Dr. Sayre said experience had taught him that support of the cervical vertebræ was necessary for a much longer time than was generally supposed. Skiagraphs of these cases were often misleading, in very many cases an excellent mode of treatment was to envelop the body and head in plaster-of-Paris, so as to combine a helmet with a jacket.

The Neuritis of Tuberculosis.—Clemente Ferraris reports a case in which all the researches and experiments made went to prove the fact already recognized clinically, that a peripheral neuritis, although reaching the point of absolute paralysis, accompanied by exaggerated reflexes, and not accompanied by alterations in sensation, may be entirely due to the toxic action of the tubercle bacillus acting on the peripheral nerves.—*La Riforma Medica.*

Book Reviews.

Nothnagel's Encyclopædia of Practical Medicine, Typhoid-Fever, and Typhus Fever. By Dr. H. Curschmann, Professor of Medicine, Leipzig. Edited, with Additions, by William Osler, M.D., Professor of the Principles and Practice of Medicine, Johns Hopkins University, Baltimore, Md. Authorized Translation from the German, under the Editorial Supervision of Alfred Stengel, M.D., Professor of Clinical Medicine in the University of Pennsylvania. Pp. 646. Philadelphia and London: W. B. Saunders & Co., 1901.

The first volume in the series of the American Edition of Nothnagel's Encyclopædia includes the topics of typhoid and typhus fevers, the main bulk of the work, however, dealing with the more important disease.

The completeness of the descriptions is in every way most admirable, practically all the possible complications, aberrations, sequelæ, etc., being presented in a way which shows the author's familiarity with these variegated fevers.

In addition to the peculiar worth of the original, we note the valuable changes wrought by the editor in his revision. Not only has he adapted it to the American reader, but has also incorporated the recent researches of Thayer on the blood conditions, Keen's work on the surgical complications and sequelæ and the different methods of bacteriological and serum diagnosis. The etiological factors in typhoid are discussed in full, and are followed by an exhaustive exposition of the pathological and symptomatic manifestations of the disease. The treatment of the subject of typhus fever will be of less interest to American readers than that of typhoid, but will well repay perusal.

An American Textbook of Pathology. Edited by Ludvig Hektoen, M.D., Professor of Pathology in Rush Medical College, in affiliation with the University of Chicago, and David Riesman, M.D., Professor of Clinical Medicine, Philadelphia Polyclinic; Instructor in Clinical Medicine, University of Pennsylvania. With 443 illustrations, sixty-six of them in colors. 1,205 pages. Philadelphia and London: W. B. Saunders & Co., 1901.

It is a pleasure to welcome a work on pathology in the English language, which presents the subject in as clear a manner as the "American Textbook of Pathology." The nineteen contributors have reason to be pleased with the results of their labors.

The work is divided into two parts—General and Special Pathology. The first part, to which about one-third of the volume is devoted, deals with the general aspects of disease, its causation and the nature of morbid processes. Chapters on tumors, pathogenic microparasites, animal parasites, intoxications, fever and teratology, complete this part. The second part is concerned with the special manifestations of disease in the various organs and systems of tissue in the body, and exceeds the usual scope of such works by including separate chapters on the special pathology of the skin, eye, and ear, which are certain to be of much value to those who have not particularly devoted themselves to the study of those organs.

The work is well and abundantly illustrated throughout, colors being employed where desirable. The descriptions of lesions and processes are clear, but concise; the discussion of theories brief and impartial. In spite of this condensation, the book is eminently readable.

We can confidently commend the work, not only to students of pathology, but also to the medical practitioner who desires a concise statement of the well-established views of pathologists concerning the diseases with which he deals in his daily work. For those who wish to penetrate more deeply into the subject, we think that more numerous references to the literature and suggestions concerning present deficiencies in our knowledge of morbid conditions would have been useful additions to the work. These, however, are matters of personal opinion, and cannot be urged as detracting from the general excellence of the work before us.

The Surgical and Medical History of the Naval War Between Japan and China, During 1894–95. Translated from the Original Japanese Report by S. Suzuki, Deputy Inspector General of Hospitals and Fleets, Tokio, 1901.

The publication of this report in English by the Japanese naval authorities is stated by them in the preface to be due to a sense of "duty to the medical profession." Much has been written about the wounds received in wars on land, indeed the medical and surgical history of the American Civil War is full of interest and information. Of naval warfare we possess no medical history; the lessons of Trafalgar and Lissa, and war between Chile and Peru have been lost to us, and there has been no previous experience in the treatment of wounded in war than the modern revolution in naval warfare.

This is a large, well-printed volume of 441 pages, translated into excellent English by Dr. Suzuki, and remarkably free from typographical errors. The book contains a number of good illustrations in colour, by Japanese artists, of wounds and injuries received in the Japanese naval forces. It may be said at the outset that the work reflects much credit on the medical authorities of the Japanese navy, and impresses the reader with the marvellous progress made along scientific lines by the Japanese, a race which was opened up to modern civilization by United States warships scarcely a generation ago. The book contains much valuable information which will not be found elsewhere, and should be read not only by naval surgeons, to whose work in warfare the subject-matter is especially applicable, but also by medical officers of the military arm of the service, who are liable to observe wounds of a character similar to those seen in naval warfare, after artillery duels, during sieges, or as a result of bombardment of land fortifications by hostile fleets.

In character, the wounds observed during the Chino-Japanese War were practically limited to such as would be produced by large projectiles, fragments of exploding shells, fragments of metal and wooden splinters. In addition, a considerable number of burns and scalds were incurred. The total number of cases of wounds and injury was relatively small, amounting to but 371, but these cases were so studied by the Japanese authorities as to be of more value than a larger number of cases less carefully elaborated. The book consists of nine sections, each divided under numerous subheadings. Section I deals of the various battles of the war, with the injuries resulting therefrom. Section II gives a history of the killed and wounded, classified by regions. Section III is of a statistical nature, dividing the killed and wounded into groups according to varying conditions. Section IV relates to the causes of the wounds received, and the characteristics of the wounds as dependent thereon. Section V treats of the complications of wounds observed. Section VI relates to the management of the wounded on shipboard. Section VII discusses the diseases experienced on board ship during the war, together with such wounds or injuries as were not the result of warfare. Section VIII treats of the sanitary conditions influencing the health of the command during the war. Section IX is devoted to a consideration of the work done in the various naval hospitals during the war.

The general scope of the book is indicated by the above sections, but it is impossible, in the space of a brief review, to touch upon the many individual points of interest which the work presents. One can only say that the book is a noteworthy addition to the scanty literature of the special subjects of which it treats, and that it should be carefully studied by medical officers of our naval and military forces, who are under many professional obligations for this latest work of their confrères of the Japanese navy. The book is a government publication, and is understood not to be on general sale, but copies have been distributed to the larger libraries, where they will be available for reference.

The Principles of Pathological Histology. By Harvey R. Gaylord, M.D., Professor of Surgical Pathology in the University of Buffalo, Attending Surgeon to the Erie County Hospital, Buffalo, N. Y., and Ludwig Aschoff, M.D., Professor and First Assistant in the Pathological Institute of the University of Göttingen, Germany, with an Introductory Note by William H. Welch, M.D., Professor of Pathology in the Medical School of the Johns Hopkins University, Baltimore, Md. Illustrated with eighty-one engravings in the text and forty full-page plates. 336 pages. Philadelphia and New York: Lea Brothers & Co., 1901.

The first fifty pages of this book, Part I, treat of "Microscopical Technique," including the care and use of the microscope and the preparation of objects for microscopical study. The selection of the methods included in this part is excellent, and the directions for using them are usually clear, so that the beginner should find little difficulty in obtaining good results. The advanced student will also find reference to this portion of the work useful to him.

Part II contains descriptions of the pathological histology of the individual organs, preceded in each case by a brief review of the normal structure of the organ under consideration. The organs of the special senses are entirely omitted, but a chapter of forty pages is given to tumors.

The third part, of thirty-three pages, is devoted to "The Principles of Optics and Photomicrography," and contains very useful information for those contemplating giving some time to this most fascinating subject. The excellent photomicrographs illustrating the book fully attest the ability of the authors in this technical field.

It is the declared intention of the authors to make the book helpful to those engaged in practical work in the laboratory, and we believe that it will prove a welcome addition to the working library. It is a little annoying, perhaps, to find silence in the second part concerning the technique most serviceable for the demonstration of particular structures, partly compensated by abbreviations, such as "F. M." "N. S.," the meaning of which is left to the intelligence of the reader. Such slips as [illegible] for the plural of septum are also the result of somewhat careless attention to details, which can be readily corrected in a subsequent edition. A valuable feature of the book is the frequent reference to the literature. We cannot close our brief review without again mentioning the excellent quality of the illustrations, both colored and uncolored. These are so true to nature that the descriptions are almost superfluous.

Bath Waters.—A Rational Account of Their Nature and Use. With Special Reference to Gout, Rheumatism, and Rheumatoid Arthritis. By Preston King, M.D., Cantab., Hon. Physician Royal Mineral Water Hospital, etc. With an historical sketch by T. Baring Gould, M.A. 128 pages. Bristol: J. W. Arrowsmith.

This little volume differs in two respects from the average health resort literature. It is written with candor and contains some positively valuable information on diagnosis, diet, and treatment, all of which appear to bespeak a large clinical observation. The author writes, "Bath is rich in heated and slightly mineralized waters, which operate neither by magic nor charm, but by their chemical and organic powers, and always in harmony with the laws of medicine." The diagnosis between Chronic Rheumatic Arthritis, Rheumatoid Arthritis, Osteo-Arthritis, and Gout is clearly brought out, as are the diet and treatment adapted to each malady. "There is no treatment for gout, but much for gouty patients." Moderation is to be observed not only by the patient in what he eats and drinks, but also by his medical adviser, so that he may avoid too slavish adherence to authority and precedent," wisely writes the author. In Rheumatoid Arthritis large experience is evidenced by his counsel to avoid all prolonged use of depressing drugs and all fanciful restrictions in diet.

A System of Physiologic Therapeutics. A Practical Exposition of the Methods, other than Drug giving, useful in the Prevention of Disease and the Treatment of the Sick. Edited by Solomon Solis Cohen, M.D., Professor of Medicine and Therapeutics in the Philadelphia Polyclinic. Vols. III. and IV., Climatology, Health Resorts, Mineral Springs. By F. Parker Weber, M.A., M.D., F.R.C.P., Physician to the German Hospital, Dalston; author of the "Mineral Waters and Health Resorts of Europe," etc., with the collaboration for America of Guy Hinsdale, M.D., Secretary of the American Climatological Association. In two vols. Illustrated with maps. 336 and 420 pages. Philadelphia: P. Blakiston's Son & Co., 1901.

The third and fourth volumes of this excellent work are fully up to the standard set by those which have already appeared, and of the editor's statement of what the aim of the work would be.

The fact that the Department of Climatology is in charge of Dr. Weber, and that the American branch of the subject is in the hands of Dr. Hinsdale, would vouch for an exhaustive treatment of this important branch of physiological therapeutics. Vol. III., Part I., opens with Physics, Physiology, and General Therapeutics of Climate, clearly but briefly describing the elements and determining faction of climate, its relation to the atmosphere, with regard to temperature, light, moisture, absolute and relative humidity, altitude and aerial current, soil and general topography. Good maps furnish graphic illustration of the mean annual isotherms, mean annual direction of ocean currents, equatorial currents being in red, polar currents in blue, and arrows showing the direction of the currents. Suggestions with regard to the availability of different climates in health and disease are made by intelligent deduction from ascertained facts.

Part II. furnishes an exhaustive recital of Health Resorts, divided under the headings of Ocean Climates and Sea Voyages, Mediterranean Climates, Island Resorts on the Atlantic Coasts, European Coast Resorts, the British Isles, and Towns of Europe. There is not a health resort of the slightest importance which is not referred to with more or less detail in these pages. The description of health resorts is continued in the fourth volume. Africa, Asia, the island resorts of the Pacific, South America, Central America, the West Indies, Bermuda, Canada, and the United States receive a thorough canvass. The review of health resorts in the United States is especially commendable, because of its minute attention to every noteworthy town or spring.

Part III., is on Climatotherapeutics, and furnishes a brief but comprehensive review of the therapeutic employment of climate, health resorts, and sanatoria. The elements of treatment at health resorts are discussed at some length—change, rest, and recreation, exercise, mechanotherapeutics, diet, milk and grape cures, mineral waters, baths, hydrotherapy, sea bathing, clothing and medical supervision, each receive separate consideration. Under the captions, "Medical Supervision," the fact is emphasized that the medical man forms an essential part of the health resort, and upon his skill and tact depends much of the usefulness of the locality. This point cannot be too earnestly impressed upon physicians sending patients away from home. Indeed, we regard it more important to know the professional caliber of the doctor than the chemical constituents of the spring.

Chapter II. treats of the selection of health resorts discussing the constitution of the patient, the journey involved, season of the year, expense of treatment, opportunity for open-air treatment, and selection of dwellings, with intelligent reference to the needs of the general practitioner. The succeeding chapters are devoted to the application of the information contained in the preceding ones, to special forms of disease and convalescence.

The practitioner has in this work a *multum in parvo* on every possible contingency, for which he may desire to apply climate as a remedial or hygienic agent. We can commend the work as a most practical one in comprehensive treatment, clear description, and judicious counsel. The index is complete and well made.

THE POCKET GRAY, or Anatomists' Vade-mecum. By the late EDWARD COTTERELL, F.R.C.S. Fifth edition, revised and edited by C. H. FAGGE, M.B., M.S. Lond., F.R.C.S., Senior Demonstrator of Anatomy, Guy's Hospital. Twentieth thousand. New York: William Wood & Company, 1901.

THIS little book of 270 pages contains an admirable condensation of "Gray's Anatomy"; the bones are omitted, but, with this exception, most of the subjects ordinarily required are presented in a way that will appeal to the overworked student. Among the best features are the tables giving the relations of the various structures, etc., and the summaries of difficult and important parts, *e.g.* the synopsis of the fifth nerve, on page 148. Of the many compends on anatomy now in the market, and all more or less popular, we can unhesitatingly recommend this as the most useful; it is solid meat from beginning to end, with absolutely no padding or theorizing; every statement contained in the volume is both correct and essential. The book represents a great deal of hard and conscientious work on the part of the compiler, and guarantees a corresponding saving of time and drudgery on the part of the student who is wise enough to use it as a companion volume to his larger textbook on this subject, and who may safely trust to it in preparing for his examinations.

SYPHILIS AND OTHER VENEREAL DISEASES. By H. DE MÉRIC, Member of the Royal College of Surgeons of England, Surgeon to the French Hospital, London, etc. New York: William Wood & Co., 1901.

THIS work, though based largely upon the author's "Notes on Venereal Diseases," stands almost as an entirely new production, due to additions and changes. A chapter on the Prophylaxis of Syphilis is among the strictly fresh material, as is likewise that on the "Contagious Diseases Act." Though only 132 pages comprise the text, there are considered in detail most of the important points connected with chancre, simple sores, balanitis, gumma, eruptions of lues and gonorrhœa, including its complications and treatment. The work is based upon years of bed-side and clinical observation in and out of hospital, and as such can be read with advantage.

A HANDBOOK OF DISEASES OF THE NOSE AND PHARYNX. By JAMES B. BALL, M.D. (Lond.), Physician to the Department of Diseases of the Throat, Nose, and Ear, West London Hospital. Fourth edition with sixty-one illustrations. New York: William Wood & Co., 1901.

THIS handbook is divided into three sections, treating respectively of General Considerations, Diseases of the Nose, Nasopharynx, and Accessory Sinuses, and Diseases of the Pharynx. Four editions within a comparatively short time show that it has found a field of usefulness. As suggested by the title, it is written from a distinctively practical standpoint, and all theoretical discussions and all historical matter are either omitted or given in a succinct form. We are somewhat surprised to find in it but scanty reference to the use of suprarenal extract, which, in America, at least, has come to be considered as second only to cocaine in its general utility in rhinological practice. Moreover, we believe that the operation of crucial incision for relief of deviated nasal septum is capable of a much wider application than is suggested by the reference to it in the present handbook. But these are matters which do not detract from the excellence of the book as a whole, and the work may be cordially recommended as a fair, complete, and reliable exposition of the topics to which it is devoted. The illustrations are notably clear, the style is terse, and the whole appearance of the book is attractive.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE RECTUM. A Practical Treatise on Fistula, Piles, Fissure, and Painful Ulcer, Procidentia, Polypus, Stricture, Cancer, etc. By WILLIAM ALLINGHAM, F.R.C.S., Eng., ex-Member of Council of Royal College of Surgeons of England, etc., and HERBERT W. ALLINGHAM, F.R.C.S., Eng,. Surgeon to the Household of His Majesty the King, Surgeon to the Great Northern Hospital, etc. Seventh edition. New York: William Wood & Co., 1901.

THE previous editions of this work have caused it to be looked upon as a standard book of reference in the special field which it covers, and the present edition represents a revision up to the present time. The authors have long had a reputation in the department of rectal surgery, and it is hardly necessary to say more than that their book is comprehensive, concise, and complete. The greatest recent changes in the surgery of the rectum have been in the treatment of malignant disease, both by radical and palliative means; and it has therefore been necessary to make some changes in the part of the volume devoted to this division of the subject, in order to bring it up to present requirements. The subject of colotomy receives a full discussion both from the anatomical and therapeutic points of view, and the text is elucidated by a number of well-executed illustrations. The present edition easily maintains the good reputation of those which have preceded it, and it will undoubtedly be found to be one of the most satisfactory books on the subject. The general make-up of the volume is excellent.

A LABORATORY HANDBOOK OF URINE ANALYSIS AND PHYSIOLOGICAL CHEMISTRY. By CHARLES G. L. WOLF, B.A., M.D., Instructor in Physiological Chemistry, Cornell University Medical College. New York, Philadelphia and London: W. B. Saunders & Co., 1901.

As an elementary aid to laboratory work in the examination of urine, with a brief survey of the chemistry of foods, blood, stomach contents, etc., this book may be commended. The attentive student of these subjects will, however, soon outgrow the limits of this little volume, without receiving any indication of where he can find further information. For example, he learns that B-oxybutyric acid has important relations to diabetic coma, p. 168; but he looks in vain for any test for, or mode of, estimating that substance. Again, under the heading "Indican," p. 137, he learns something about that substance, but he receives no hint that over-oxidation with chlorin must be avoided in order to detect the indican. Furthermore, he gains no conception of the relations between indican and indol, and their connection with intestinal putrefaction. These and many similar omissions may not be serious when the book is used under the supervision of an instructor who supplements the information it contains, but they materially affect its value as a book of ready reference for those bearing the responsibilities of medical practice.

THE SURGICAL TREATMENT OF DISFIGUREMENTS AND DEFORMITIES OF THE FACE. By JOHN B. ROBERTS, A.M., M.D., Professor of Surgery in the Philadelphia Polyclinic, etc. Second edition, with a chapter on the reconstruction of Syphilitic Noses. Illustrated with sixty-two figures. Philadelphia: The Philadelphia Medical Publishing Co., 1901.

WE had occasion only a few months ago to review this brochure in its first edition when it embodied the Mütter Lectures for 1900. In its present form it differs from the previous edition in having an added chapter upon the treatment of the well-known deformities due to destruction of the bony and cartilaginous septum of the nose. This chapter occupies only a few pages, but it contains many concise directions as to the management of cases of nasal deformity. The author emphasizes the fact that we need not fear operating upon such patients on account of the syphilitic taint, since their tissues seem to heal, under favorable circumstances, as well as any others. Many points of interest are noted, but there are one or two diagrams which we hope to see suppressed in future editions.

Medical Items.

Contagious Diseases Weekly Statement.—Number of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ended January 25, 1902:

	Cases	Deaths
Measles	[illegible]	[illegible]
Diphtheria and croup	[illegible]	[illegible]
Scarlet fever	[illegible]	[illegible]
Smallpox	[illegible]	[illegible]
Chickenpox	[illegible]	[illegible]
Tuberculosis	[illegible]	[illegible]
Typhoid fever	[illegible]	[illegible]
Cerebro-spinal meningitis		[illegible]

Medical Treatment in Afghanistan.—Dr. Gray, in his work "At the Court of the Ameer," thus describes a treatment for various maladies prevalent in Afghanistan: "For fever, dyspepsia, gout, headache, or any feeling of malaise, the barbers bleed their patients. In addition to these, which may be called the irregular bleedings, there are regular bleedings every spring and autumn. These are generally done out of doors by the roadside. The barber, squatting down by the side of his patient, makes his incision at the bend of the elbow, fortunately, not into the vein immediately over the great artery of the arm, the one usually bled from in England, but into one alongside. The patient holds out his arm, and allows the blood to drip on to the ground till he thinks enough has run away. There is not the slightest attempt made to measure the quantity of blood lost. The only precaution taken is to avoid drinking any water for twenty-four hours afterward, lest it should mix with the rest of the blood in the vein and make it thinner; if they do drink any, they hold the wounded arm above their heads to prevent the water running into it."

Incidence of Smallpox as Regards Vaccination.—Up to the beginning of December, 349 cases of smallpox, in the present outbreak in London, had been "completed"—that is to say, had ended in death or recovery—and from an evidently authorized statement it appears that the borough of St. Pancras heads the list with 24 cases. The number is rather small for statistical purposes, but so far it appears that after the age of fifty the liability to smallpox is slight. Of the 349 cases, 116 ended fatally. This is, of course, a high rate; but it must be taken into consideration that since death usually takes place at a comparatively early stage of the illness, the fatal cases are in advance of recoveries.

These were distributed as follows:

Vaccinated, 233 cases; deaths, 47, rate of mortality, 20 per cent. Unvaccinated, 97 cases; deaths, 47, rate of mortality, 60 per cent. Doubtful, 19 cases, deaths, 58, rate of mortality, 57 per cent.—*Public Health.*

A Newspaper Description of Leukæmia.—The following is a fair sample of newspaper portrayal of clinical medicine: "Mrs. Horace Fries, of 4931 Penn street, Frankford, who died on Wednesday in the University Hospital from a disease that excited much comment among physicians, went to the University Hospital some weeks ago. There she was told that she had a complication of disorders, and the physicians say that there was a separation of the red blood corpuscles from the white. If she had survived long enough her blood would have become white. Physicians declare that there is no known cause for this and no cure."

Vaccination League.—A number of medical men and others have thought this a fitting time to form a new vaccination league in Great Britain. Among its supporters are Mr. Jonathan Hutchinson, Sir Alfred Garrod, and Professor Charles Stewart.

Number of Deaf Mutes.—There are 27,000 deaf mutes in France, and more than 1,000,000 probably in the world. There seem to be more in countries where we find most intermarriage and the worst social conditions. Among the Hebrews there are more deaf mutes in proportion than among any of the nations where they live, probably due to more frequent intermarriage.—*Medical Magazine.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended January 25, 1902:

SMALLPOX—UNITED STATES

THE DIAGNOSIS OF PERICARDITIS.

By ARTHUR R. EDWARDS, A.M., M.D.,
CHICAGO.

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE, NORTHWESTERN UNIVERSITY MEDICAL SCHOOL (CHICAGO MEDICAL COLLEGE); ATTENDING PHYSICIAN TO COOK COUNTY, ST. LUKE'S, MERCY, AND WESLEY HOSPITALS.

THE definitive diagnosis depends on the physical findings, which are, therefore, first discussed.

I. *Inspection.*—Precordial prominence, *voussure*, first noted by Louis, may occur when the chest is plastic, as in women, in children, and when the intercostal muscles are paretic. The left chest often moves less than does the right. An epigastric tumor-like bulging of the luxated liver was noted by Auenbrugger and Corvisart.

The apex beat is somewhat lower when exudation depresses the diaphragm; it is more horizontal, more to the left, and the dulness of an effusion transcends the apex to the left. The greater the effusion, the weaker the apex becomes, and disappearance of the previously distinct apex is all important. On bending forward, the apex usually reappears.

The interspaces may bulge. Collateral œdema of the chest wall (Rendue) is most rare. Undulation, described by Senac, is not due to the exudate, but to the heart itself. Swett described it in the epigastrium. Graves and Stokes described tumor-like extrusion of the compressed lung above the clavicle. According to Ewart, the upper edge of the first rib can be felt as far as its sternal attachment, being separated from the clavicle ("first rib sign"). The thoracic wall veins are large. During convalescence, the apex may retract during the systole. The decubitus is usually dorsal, rarely on the left side; the head and shoulders are usually elevated, and the attitude is rarely changed. The knee-hand position was noted, Zehetmayer's case. Guttmann holds that the apex never wholly disappears.

II. *Palpation Confirms the Location of the Apex.*—The friction thrill is often felt. In Fuller's cases of palpable rub, there was always some external pericarditis favoring conduction of the true pericardial friction. Disappearance of an apex beat previously observed with a strong radial pulse is very important, since mere absence of the apex is observed in many conditions.

The friction may exceptionally originate in tubercles, cancer, calcification, maculæ tendinæ, etc.

Epigastric tenderness to either side of the ensiform, or between the attachments of the sternocleidomastoid muscle is due to participation of the phrenic nerve (Guéneau de Mussy and Peter). Fluctuation is practically never felt.

III. *Percussion.*—Usually 100 gm. of fluid are required for distinct physical signs, though Fraentzel has detected 50 to 60 in favorable cases. According to Ferber, there are two complementary recesses in the pericardium, the first over the basal vessels, where the fluid may accumulate, revealed by a triangular dulness whose apex is directed downward (Skoda, von Dusch, Oppolzer, Rosenbach), which may compress the large veins or arteries; and the second in the fifth right intercostal space (Rotch-Ebstein), the fluid exudate here replacing the relative liver dulness, and recognized best by palpatory percussion. Extensive or enormous exudates of (chronic) pericarditis produce an outline usually designated as triangular, with the blunted apex upward, or as pyriform with the base directed downward. The dulness may even reach the interclavicular notch above the right nipple, the left axilla, impinging on Traube's semilunar space, extending beyond the left lobe of the liver, and markedly depressing the diaphragm and liver. Very massive exudates may be mistaken for pericarditis plus pleurisy with effusion. While the outline is roughly triangular, the right border is more vertical in contrast with the oblique left border, which is beyond the apex beat, if the latter remains visible (Skoda). The dulness varies with fluctuations in the effusion and resorption.

Dulness may be one-third to one-half more in the erect than in the dorsal posture (Gerhardt), but this is not invariable, since the lung borders must be normal and the exudate freely movable. Sahli has found increase in dulness by the sitting posture in enlarged hearts and in valvular disease, which he explains by depression of the diaphragm or by posture emptying the auricles of blood. He places more stress on the lateral than on the upper border. Setting the patient up is usually unnecessary and often dangerous. Change of the dulness, especially when the patient lies on the right side (Rosenbach), is important, since this is uncommon physiologically, whereas change of dulness in the left decubitus is of minor value.

Dulness may persist from cardiac dilatation or from pulmonary retraction. The effusion may be enormous (10 liters, Kyber; one gallon, Clark; eight pounds, Corvisart), and lead to a diagnosis of pleurisy alone, or pleurisy complicating pericarditis. Shattuck renounces all faith in the characteristic dulness.

IV. *Auscultation Reveals the Chief and Most Reliable Diagnostic Sign, the Pericardial Friction Due to Attrition of the Inflamed Serous Pericardial Surfaces.*—Usually it is a rubbing "to and fro," located over the base, and is deficient in precision of rhythm; it is usually increased by pressure and deep inspiration, is *very superficial, i. e.* close to the ear, is not propagated widely, and is often short-lived; it is variable as to the heart's phases and acoustic quality, and is not dependent on the intensity of the inflammation, but rather upon the accidental quality of the effused lymph and its location. Disappearance of the rub is explained by (1) Regression; (2) Exudation; (3) Adhesions; (4) Weak heart. The heart tones are usually more or less weakened and distant.

Laennec described the friction without fully appreciating it; Collin, in 1824, and Latham, in 1826, described it, but Stokes most fully elaborated it in 1831. In quality, it may be harsh, soft, whistling, creaking, crunching, musical, or even metallic (resonance from the stomach or intestines). In contradistinction to pleurisy, it may be present even with great exudation (Stokes), especially at the base, since here the heart may displace the fluid and touch the parietal pericardium.

In location, while it is most often heard over the base, it may be present over the sternum or the tricuspid region, where it is especially significant. It may also be heard over the apex. Different in precision, it is not exactly synchronous with either cardiac phase, anticipating or falling behind the systole or diastole, which character is more clear when the heart rate is slow. It is single, double, namely late in the systole (Sahli, Geigel), mesosystolic or meso-diastolic; it may be triple, *i. e.* presystolic, systolic and diastolic, or even quadruple. It is sometimes absent in tuberculous (Mayne, MacDowell, Leudet) or purulent inflammation. Superficiality of the friction sound is absent when partial adhesions exist anteriorly and the fluid accumulates behind.

Moderate pressure usually increases the friction, especially in plastic chests, yet pressure may also accentuate valvular murmurs. Much pressure may inhibit the cardiac action (Friedreich). Change of posture (Corrigan, Stokes) often makes the murmur clearer, as on leaning forward.

While the propagation is not wide (*il naît et meurt sur place*, Jaccoud), yet it has been heard at a distance of nine feet. In children, it may be heard over the whole chest, and we have seen the same in adults. Hydrothorax (Graves) has been thought to favor its propagation, and cardiac hypertrophy by bringing the heart closer to the chest wall propagates the friction more widely (Stokes). Usually the murmur ceases abruptly when the stethoscope has been removed a short distance. It does not follow the lines of propagation heard in valvular heart disease.

Sears describes a case in which the friction was clearest at the angle of the left scapula.

Respiration usually increases the murmur (Traube), due to the closer apposition of the pericardial leaves by the movable wedge of expanding lung. (Sometimes it is more marked during expiration [Lewinski, Paul], in adhesions between the heart and lung [Riegel] and also without lung fixation.)

The murmur may last but two to six hours.

It is frequently stated that as exudation increases, the friction disappears, to reappear during absorption. "The friction increases upward during exudation, and downward during absorption" (Sibson). Nevertheless, friction often persists in large exudations, if indeed its persistence is not the rule (Walshe). Balfour claims that friction once heard is never effaced by even the greatest effusion.

Secondary Physical Signs.—Evidences of cardiac incompetence are due to mechanical pressure hindering the diastole, especially of the auricles, inflammatory or degenerative myocardial alteration or coincident cardiac disease, etc. They are hepatic and renal stasis, ascites, œdema, cyanosis, dyspnœa, cerebral anæmia (syncope), etc. Traube held that the heart's action was stronger because the fluid was less resistant than the pericardial walls.

The pulse at first suffers irritative acceleration, but lasting frequency speaks for myocardial change. It may exceptionally be normal, or even slowed (36). There is no characteristic pulse. Dicrotism is frequent. The pulsus paradoxus is seen (Traube). A very strong or water-hammer pulse may suggest underlying valvular disease. Irregularity has been recorded (Louis, Gendrin). The pulsus differens occurs (Traube).

Lung compression: Bamberger observed a small area of compression, the size of a dollar, at the angle of the left scapula, where bronchial breathing, dulness, and increased fremitus are noticed, which clears up in the knee-chest posture, etc. (Pins). Puncture excludes fluid in cases of doubt. Shattuck denies Bamberger's sign, which Allbutt has also seen in hæmopericardium. There is tympany (or dulness) under the left clavicle and to the left of the heart in fair-sized effusions. (Ewart describes tubular breathing near the right mamma.)

Vomiting, singultus, dysphagia (Morgagni, Gendrin, Stokes), even of the hydrophobic type, recurrent paralysis (Landgraf, Riegel, Bäumler) and slow pulse are pressure symptoms.

Walshe observed tracheal compression. The second pulmonic may be accentuated and Warthin holds it an early sign. The second tone may be split (Skoda).

Metallic heart tones may be due to an adjacent cavity, pneumothorax, or the stomach and intestine. A systolic non-valvular murmur over the aorta has been explained by pressure on the vessel (Walshe, Friedreich), or inflammatory relaxation of the vessels (Zehetmayer) interfering with their normal vibration. Organic or accidental murmurs may occur. Gerhardt observed splenic pulsation.

Symptoms.—All symptoms are frequently absent, and no symptom is diagnostic. Osler's statement that "probably no serious disease is so often overlooked" finds confirmation in the earliest observations of Latham, Graves, Stokes, Shattuck, and Letulle. Leudet found total latency in 55 per cent. of cases.

Fever may exist, but follows no set type (Wunderlich). It is often absent, especially in secondary pericarditis and may run below normal, even in purulent effusions. High fever is infrequent.

Dyspnœa, thoracic oppression or constriction and cardiac asthma occur. Oppolzer observed cyanosis without dyspnœa when the pulmonary circuit remained intact. Dyspnœa is due to vagus irritation, venous, cardiac, pulmonary, and arterial compression.

Pain is variable and often is missed in secondary pericarditis. Severe pain was considered indicative of pleurisy (Bouillaud and Bamberger). Epigastric pain may precede pain elsewhere (Guéneau de Mussy). Anginal pain (Andral) radiating to the shoulder, arm, and neck, is rare.

Cerebral symptoms in rheumatism, etc., should suggest pericarditis, *e. g.* delirium, mania, choreiform movements, convulsions, psychoses (Burrows and Flint), but may be due to complicating uræmia, endocarditis, etc. Gastritis may be suggested from the symptoms, while pericarditis is found on examination.

The etiological diagnosis is important, since pericarditis is almost invariably secondary.

I. Infective diseases, of which rheumatism is foremost (Pitcairn, 1788), being most frequent (Bamberger) when many joints are involved and when the process extends rapidly from joint to joint.

Probably many "primary" cases are rheumatic. It occurs with recurrent rheumatism with endocarditis. Usually it develops rather early, but may precede arthritis (Stokes, Graves, Trousseau). Commonly sero-fibrinous, most exceptionally is it purulent.

Other infections, as pneumonia (especially in the streptococcus type, Banti), septicopyæmia, scarlatina, tuberculosis (multiple serous inflammation, pleuritis, peritonitis), etc., etc.

II. By contiguity from adjacent organs, pleurisy, pneumonia, aneurysm, disease of the ribs, sternum, spine, œsophagus, stomach, spleen, liver, peritoneum, myocardium, endocardium, etc., and from cervical cellulitis (diphtheria, etc.), or mediastinitis.

III. In cachexiæ or dyscrasiæ, carcinoma, in 3 to 10 per cent. of nephritis (especially contracted forms), alcoholism, blood diseases, scurvy, etc., often as a terminal infection where it may be overlooked.

Differentiation rests upon (1) The friction, or (2) The dulness, or both. Special subdivision into types, as acute or chronic, fibrinous, sero-fibrinous. sero-purulent, purulent, ichorous, hemorrhagic, etc., is inadvisable as a general proposition. Puncture alone reveals the character of the exudate. Usually fibrin-formation and serous exudation coexist (Latham).

I. The pericardial rub is practically pathognomonic of pericarditis (von Dusch).

It has been observed in cholera from dryness of the tissues (Leichtenstern, Peischl), in soldier's spots (Gerhardt, Pazzolo), hemorrhage (Wagner), hypertrophied heart (Gendrin, Seitz, Lépine), inflammation of the diaphragm (Walshe), or peritoneum (Emminghaus).

From endocardial murmurs, the acoustic quality, superficial character, inconstancy, lack of precision, variability with posture, slight propagation, palpatory difference in the fremitus, basal location, and increase of the pericardial friction by pressure or inspiration are most decisive. Sometimes pericardial friction covers an endocarditic bruit. The distinction is sometimes difficult, between an aortic to-and-fro murmur and pericardial friction. Valsalva's experiment, *i. e.* a long inspiration with closed glottis followed by expiration with tense abdominal muscles, intensifies pericardial friction and decreases endocardial murmurs. Bearing in mind the great frequency with which pericarditis is a complication (or co-ordinate phenomenon) of endocarditis, this special point demands reserve in the prognosis, since the valvular disease remains after the pericarditis subsides.

From pleuropericardial friction (pseudo- or extra-pericardial), originating in the inflamed pleura, where friction depends not only on respiration, but also on the heart's action. The usual differentiation lies (1) In the closer connection of the pericardial rub with the cardiac activity, persisting during expiration, and (2) The location of the pleuro-pericardial friction in the sinus mediastino-costalis, along the lingual lobe, in its intimate relation to respiratory movements, and in its usual cessation at either extreme phase of respiration, inspiration or expiration (Stokes, Addison).

This method of differentiation is not infallible. Inspiration also augments true pericardial friction, which is, however, increased by bending forward. Valsalva's test (*v. s.*) is also useful. Pericardial friction toward the base or sternum is less often confused with pleural friction near the heart. Rosenbach finds differentiation most difficult when the basal vessels pound against a tuberculous cavity or a pneumonia. (As a sequence of pleuritis pericardiaca, Riegel observed an expiratory lessening of the apex beat due to pulling of adhesions.)

From the præcordial emphysema murmur, differentiation is possible in the crackling sounds of interstitial emphysema or air in the anterior mediastinum. The sounds resemble râles, but are closely associated with the heart's action, and are often metallic. The condition of the heart tones, etc., is decisive.

From pericardial splashing (see pneumo-pericardium).

II. The dulness of pericardial exudation.—The typical pyriform or triangular dulness is modified by pleural or pericardial adhesions, pulmonary emphysema, etc. The relative cardiac dulness may be markedly increased with little change in the absolute.

Hydropericardium and effusive pericarditis may be confused, since stasis with hydrops pericardii may intervene in pericarditis the friction may be absent or disappear, and fever may be lacking (chronic pericarditis). The etiological diagnosis of hydropericardium, *i. e.* local pericardial changes or a general cause for hydrops, with previous anasarca or hydrothorax, which almost always develops first, on the one hand, or, on the other hand, the etiological factors of pericarditis, may easily determine the difference. Hydropericardium is less apt to produce high dulness. Digitalis and purges favor resorption of transudation rather more readily than of exudation, in which latter event friction sounds would probably reappear. Paracentesis is not imperative for differentiation, but would reveal the usual differences in opacity, specific gravity, and albumin percentage between exudates and transudates. The triangular dulness may be very marked in hydrothorax, since there are no adhesions; friction is absent, and the fluid almost always contains some sugar. Potassium iodide passes readily into transudates (see pleurisy, page 201). Hæmopericardium, from trauma and rupture of a coronary artery, ventricular or aneurysmal rupture, etc., is commonly sudden, is attended by syncope, and blood is removed by puncture.

From pneumopericardium (*q. v.*).

From cardiac dilatation, the differentiation may be most difficult, especially with dilatation plus hydrops pericardii, when drastics, digitalis, friction, the history, and evolution only may decide. The very distinctive relation between the apex and the outer dulness to the left is rarely fallible (*v. s.*). If the pulse is strong and the apex weak, pericarditis is present (with, of course, the typical dulness, etc.); yet compression or weakness of the heart in pericarditis necessitates a weak, rapid pulse. Schott's resisted movements, like digitalis, may decrease dilatation. In both affections the heart's dulness is increased by leaning forward, which may, however, bring out the apex well within the dulness of the exudate. When the patient lies on his right side the apex in pericardial effusion becomes visible (Rosenbach), which does not obtain in enlarged heart.

From retraction of the left lung away from the heart: The diaphragm is high, the apex and outer cardiac dulness coincide, the spleen is high, the pulmonary artery is exposed, and the proper signs of pulmonary contraction are elicited (Leube).

From mediastinal tumor: The dulness is irregular; there is no variation of dulness on postural change; the signs of increased conduction, etc., are noted, with the absence of the cardinal signs of pericarditis.

From aneurysm; marginal infiltration of the lung; callous pleura; encapsulated pleurisy, superabundant fat (Walshe); anterior mediastinitis (usually with friction, but with more vertically elongated dulness).

Diagnosis of the Character of the Exudate.—The fluid is sero-fibrinous in rheumatism, ichorous in perforation from hollow viscera, hemorrhagic in scurvy, carcinoma, tuberculosis, hemorrhagic exanthemata and alcoholism, purulent in sepsis, empyæma, etc.; yet paracentesis is the only certain test, since exceptions are frequent. Tuberculous pericarditis, even in clearly tuberculous cases, can be diagnosticated positively only by detection of tubercle bacilli in the aspirated exudate.

103 State Street.

Some Cases of Acute Contagious Articular Rheumatism.—G. B. Allaria reports three cases which were characterized by contagiousness, and by the beginning of the disease with angina of the throat. In a fourth case, the angina reappeared with every reappearance or exacerbation of the articular symptoms. Bacteriological investigations of the exudate on the tonsils showed in each case a streptodiplococcus which was almost identical in structure and behavior with that found by Meyer in the same affection. Animals inoculated with this microorganism developed lesions in the joints.—*Rivista Critica di Clinica Medica.*

DENGUE, A STUDY OF ITS MODE OF PROPAGATION AND PATHOLOGY

By HARRIS GRAHAM, M.D.
OF BEYROUTH, SYRIA
PROFESSOR OF PATHOLOGY, AMERICAN COLLEGE

ALTHOUGH the literature of dengue is quite voluminous, and a large number of valuable reports have been made of different epidemics—from that of Java, Cairo, and Alexandria in 1779, to that of the eastern end of the Mediterranean in 1889—yet nothing definite has been ascertained with regard to either its mode of propagation or its pathology. A number of autopsies have been made, but no definite anatomical lesions have been found. At one time it was considered a purely miasmatic infection, but since the epidemic of 1889 a strong opinion has prevailed among those who have given the matter careful study that it is a purely contagious disease. O. Lichtenstern of Cologne (in Nothnagel's "Specielle Pathologie und Therapie," IV. Band) sums up a very careful study of the whole literature by saying that it belongs to "den contagiös-miasmatischen Krankheiten." He believes that it is contagious, but that the contagion requires for its propagation certain miasmatic influences, and without these the contagion is powerless to spread.

The rapidity with which dengue spreads from one house to another after entering a city, and from one member of a family to another, having once entered the household, shows that it must be highly contagious. (See E. von Düring, "Denguefieber in Constantinopel," *Monatshefte fur praktische Dermatologie*, 1890, 2, S. 16 ff.; Mahé, article "*Dengue*," *Diction. Encyclop. des Sciences Méd.*, Zulzer, Mordtmann, Skoltowe, and others). On the other hand, the inability of the disease to spread, when introduced into other regions than those in which the miasmatic conditions are favorable, has forced many accurate observers in the East and in America to the conclusion that it is not a contagious but a miasmatic infection. (See Orenstein, "Zur Dengue-Frage," *Deutsche medicinische Wochenschrift*, 1890, 2; Wernich-Eulenburg's Realencyklopädie, 1886, V; Chryssochoos in Smyrna, A. Hirsch, and others.) There is a great multiplicity of evidence to show that it does not spread to any extent when carried away from certain low-lying regions, which are its favorite abode. Epidemics in Cuba, Jamaica, East Indies, Reunion, Martinique, and Madagascar, all seem to show that, in spite of the most active communication, dengue cannot spread to any extent when carried into dry and high places in the interior. These epidemics have shown time and again that people come down from these higher and drier places, contract the disease, and then have it break out on them in their homes to which they have returned, and there lie smitten with it for several days without the other inmates of the household catching it. Up to the present time no logical explanation has been offered us by which we can reconcile these two theories of its propagation, the one miasmatic and the other contagious.

Early in July of the year 1901, the city of Beyrouth in Syria was visited by an epidemic of dengue. It began slowly, but as it increased, it seemed to gain force and virulence, spreading through every part of the city and the outlying villages. During this epidemic, which has been a very severe one, few houses in the city have escaped, and usually but few members of a household have been spared when the disease has once found an entrance. The epidemic has been a typical one, the fever lasting from three to eight days, rarely ten or twelve, and as it passed away, in the majority of cases, it produced an eruption more or less marked. In a considerable proportion of the cases (in my own practice 30 per cent.) there has been after a certain interval—five to fifteen days—a sharp second attack. The second attack I have never seen without an eruption, and in none of the cases has the patient been entirely well between the attacks. The eruption in the first attack has been the rule, and there has been marked desquamation from it in about half the cases. I also saw during the epidemic several well-marked third attacks, the patient in no case having fully recovered himself between attacks. A description of the epidemic would differ in no particular way from the classical ones given by Manson and others.

I saw something of the epidemic which prevailed on the Syrian coast in 1889, and my experience of that and what I had been able to learn from a careful study of the reports of similar epidemics by others had lead me to believe that the link, which would join together the two theories with regard to the propagation of the disease, was to be found in the mosquito. I believed that the mosquito was the condition or necessity, in order to make the disease portable from one individual to another.

The city of Beyrouth offers peculiar advantages for a study of this kind. It is situated on a cape, almost a peninsula, I might say, with a sandbank behind it on one side and irrigated mulberry orchards on the other. The Lebanon Mountains rise almost directly from the limits of the city, reaching in places an elevation of 9,000 feet. The slope facing toward Beyrouth is dotted with villages, and around them the ground is terraced on all sides and cultivated for the most part with mulberry trees for the silkworms. The city is terribly infested with mosquitos. Professor Day, of the department of natural sciences in the college, has found among them only certain forms of the culex. Most all the villages on the mountain side contain a certain number of mosquitos, which are also only the culex. Some of the villages in the drier parts have none.

At the beginning of the epidemic I commenced a series of experiments, in order to determine, if possible, whether the culex which exists in perfect swarms in the city could carry the dengue from person to person.

The first experiment was done with a mother and her nursing child. The day the mother was taken with the initial chill, all the mosquitos in that part of the house were killed by generating chlorine gas in the rooms. As she changed from one room to another, the rooms were, from day to day, ridden of the pests by means of chlorine, and netting upon the windows kept others from entering. The child, which was eight months old, was allowed to nurse from the mother during the whole course of the fever, and was constantly in her arms. Care was taken to keep away the mosquitos for ten days, after the temperature had fallen to normal. The mother had an eruption on the fifth day, which did not desquamate. The child escaped without fever or any other symptom of dengue.

In experiment No. 2, four children occupied the same room as a sleeping room. This and the adjoining room, which was used as a nursery, were freed from mosquitos the day the youngest child, four years old, was taken sick. During the whole course of the disease, and for eight days after the temperature dropped to normal, the two rooms were kept carefully free from the mosquitos. The eldest child was eleven years of age. The children all slept under the same cover on the floor, and played together during the day time, and yet none of the other three children contracted the disease. In experiment No. 3, the father of three children brought the disease to the house. He was anxious to keep his wife and children from the illness, and submitted to the daily annoyance of a disinfection of either one side or the other of his house. The fever in his case lasted five days, and ended with an eruption which desquamated, but no other member of the family was taken ill. Several other experiments of the same kind were made, and in each case in which the directions were carefully carried out, the result was the same, viz., that the dengue did not seem to be contagious when the mosquitos were carefully kept out of the house.

Feeling that these results were negative in one sense, I carried on several experiments in direct inoculation. As dengue is a disease not dangerous to life, and not accompanied by serious complications, followed by grave sequelæ, I believe these experiments to have been justifiable. It has been a very easy matter for a sum of five dollars, each, to get any number of strong young men willing to run the risk of being sick a week with the dengue.

In the city I made four different attempts to convey the disease by means of the culex. In each case the mosquitos were taken from inside the sick man's netting, and put inside the netting where the candidate for the disease slept, and there left until the latter was taken ill. In no case was the man allowed to leave the house or to receive visitors, and in each case no one had been sick with the disease in the house where the candidate slept. Patient No. 1 was taken ill with the initial chill five days after the mosquitos were put in. In case No. 2 the fever began six days afterward, and in case No. 3 the fever began on the fourth day after. In the fourth case, the man slept eight nights under the netting with the mosquitos, but did not fall ill. I again put in a larger number, which I left under his netting for a week without avail. He said that in the epidemic of 1889 he had had a very severe attack lasting six days, accompanied by high fever and an eruption.

These experiments seem to prove the possibility of the culex carrying dengue directly from one person to another; yet in a city where the disease was so prevalent, it might with justice be argued that the disease had been contracted in some other way. In order to avoid this objection, the mosquitos taken from a dengue patient were put in a pasteboard box, and I carried them to the mountains after taking a bath and changing my clothes. The mountain village to which they were carried has an altitude of 2,500 feet. No case of dengue had occurred there up to that time, and I believe there has been none since. Two young men, both in good health, residing in different parts of the village, were found to submit to the experiment. Both of them said they had never had the dengue before. The mosquitos were put under their nettings the afternoon of the 15th of September. On the 19th one was taken with a chill in the morning, and toward evening of the 21st the other. Both of them had typical attacks of dengue. Neither of them had been to Beyrouth or to any other place where cases of dengue existed. Most of the villages of the Lebanon have had some cases of dengue during this epidemic, but most of them contain a sufficient number of mosquitos to carry it about. It seems to me clear that the first class of experiments proves that, failing mosquitos, the dengue is not a contagious disease; and the second class evidences in direct inoculation that certain forms of culex may carry the disease from one person to another.

A very disagreeable experience which I had in 1889 goes to prove the truth of the first of these statements. I spent one night in the city of Beyrouth early in the epidemic, and then returned to our camp, 4,500 feet high, in the Lauras Mountains. Here were no mosquitos. Six days after leaving Beyrouth, I fell ill in our cabin, where there were twelve of us, with a very severe attack of dengue. I did not know what was wrong with me, as it was the first case I had seen. The fever lasted six days, and the eruption which came out toward the end was followed by desquamation. The other eleven in the cabin came and went freely, taking no precautions to prevent contagion, and yet none of them was taken ill.

Being convinced that the mosquito was the means of carrying the disease, I was forced to the conclusion that the cause must therefore be sought in the blood; and, hoping there to find it, I have carefully and systematically examined the blood in a very large number of cases. I must say that I chose for examination only those in which the fever was high, the constitutional symptoms marked, and the course of the disease typical. The lighter cases in which the temperature was at no time higher than 101° F., I did not take the time to examine. After having examined a certain number of cases, I was struck by the presence of an amœboid form in certain of the red blood corpuscles, and having once definitely found it, I was able to discover it after careful examination in all of the cases without exception which I examined. In all, over one hundred cases were examined, and in no case in which I had the time to examine the blood carefully before the specimen was spoiled did I fail to find it.

It resembles in many ways the plasmodium malariæ, but its cycle of production or formation in the human blood is so much longer than that of the malarial parasite that the changes in its life phase come more slowly and are more difficult to follow. Fresh preparations, no matter how carefully made, do not keep long enough to enable the observer to follow it through any great extent of its life. Long before the parasite has changed its form to any other more advanced, the specimen is so degenerated as to be worthless. The fever lasts in these cases from four to ten days, and in order to see the parasite in different stages, an attempt had to be made to find cases of the fever in series, as it were, from the initial chill to the end of the disease. In order to accomplish this in every case where I examined the blood, I kept as close a record as possible of the time from the initial chill or onset of the disease when the blood was drawn. The record of this time I endeavored to make as exact to the hour as possible. In this way I was able to make a fairly well connected history of the growth of the parasite. The specimens were drawn and made in the usual way—slides, cover-glasses, and finger-tips being kept as clean as possible. The specimens in each case were immediately rimmed around the cover-glass with vaseline, and the specimens thus protected from changes as long as possible. The blood was drawn in most cases from the finger-tip. In a few cases where the eruption was very pronounced the blood was drawn from the center of some of the brightest spots. I might here say that these specimens did not present features in any way different from those found in a drop drawn from the finger-tip of the same patient. An attempt was made to gain additional information by staining, the cover-glasses being prepared according to Ehrlich's method, and stained at times with Löffler's methylene blue, at times with borax methylene blue, and with Ehrlich's stain; but the results were not so satisfactory as those obtained with specimens of perfectly fresh blood. However, most people who have worked in stained specimens of malaria parasites know that even the most carefully done work in this line may turn out but poor results.

The illustrations here presented were drawn from different specimens as seen with a Zeiss 2 mm. oil immersion apochromatic system—and compensating oculars 6 and 8. Of course, none of these figures represent any one field under the microscope, but are samples drawn from many fields examined and put together to show in a small compass as many phases of the parasite as possible. In Fig. 1 may be seen the parasite in its early stages, that is in the first thirty-six hours. Sometimes it is seen in the center of the red corpuscle, and sometimes at the margin. From time to time it changes its shape, showing amœboid movement and shifting its place from one part of the corpuscle to another. It need not be mistaken for a vacuole, for it is too dull in color, lacking that clear brightness seen in a vacuole.

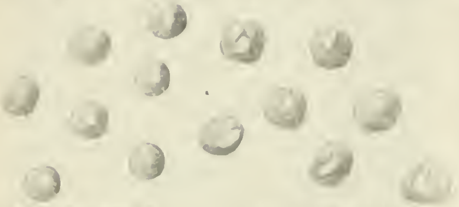

Fig. 1.—Parasite in first 36 hours.

Fig. 2.—Forms seen from 2d to 4th day.

In Fig. 2 the parasite is shown in a later phase of its cycle, and this is the form in which it is usually seen. Careful search may have to be made to find it, but when that is made one is certain to find several good specimens in an ordinary typical case of dengue. It is evidently a protozoon, but differs from that of malaria in its life history, and in that it forms no pigment from the beginning to the end of its growth. It is true that Marchiafava and Celli have discovered and carefully described an unpigmented quotidian parasite, but this differs also in other ways from the hæmatozoön of the dengue. I know of no parasite which resembles it so much as the Pirosoma bigeminum (Boophilus bovis). It is like the pirosoma mostly ovoid in form, and it very frequently shows that same sharply pointed end so often found in the parasite of Texas fever. The pirosoma is unpigmented and so is the *Hæmatozoön denguii*. I have, however, never seen it in pairs, or received any suggestion that it multiplies by binary division, as in the case of the pirosoma. This sharply pointed end may be seen at times to turn around inside the red blood corpuscle, and at times when it has attained a certain size to push out like a pseudopodium past the margin of the corpuscle. The best examples of it and the largest I have seen have been in blood that has remained on the slide for a few hours, and which has been kept from undergoing decomposition.

Fig. 3.—Corpuscles about to rupture.

Fig. 4.—Forms seen about 4th day or over, with remnants of red corpuscles already ruptured and unruptured corpuscles.

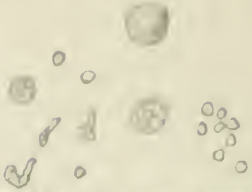

Fig. 5.—Parasite escaped from red corpuscles and presenting changes of form and degeneration.

In Figs. 3 and 4, the parasite is seen still further advanced and about the fifth or sixth day many portions of broken corpuscles are seen scattered throughout the field. In specimens prepared from the fourth or fifth day, which have stood for a couple of hours, frequently the hæmatozoön is found pushing its way out from the remnants of a corpuscle, or it is seen with the mere outline of a corpuscle around it. Very soon after its escape it is seen to undergo degeneration. I have never seen a white blood corpuscle swallow one when the parasite was making amœboid movement, but have frequently seen degenerated or degenerating forms of the parasite engulfed by leucocytes as seen in Fig. 6. In Fig. 5 may be seen certain degenerated and degenerating forms of the parasite. The white blood corpuscles seem to clean these up very rapidly from the blood plasma.

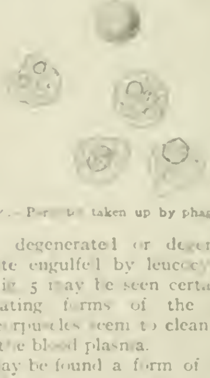

Fig. 6.—Parasites taken up by phagocytes.

In Fig. 7 may be found a form of parasite, I believe to be a flagellated one, rolled up, as it were, inside a membrane. Some of the flagella are seen in the illustration, which is drawn as closely as possible from specimens under the microscope, to be in the act of pushing outside the cell wall. In Fig. 8 flagella may be seen among the red blood corpuscles. They have a distinct undulatory movement by means of which they progress, making their way among the corpuscles, pushing them aside or steering around them. Some of them have a distinctly clubbed end. These illustrations have been taken from blood examined during severe second attacks, and these free flagella were found only after the blood

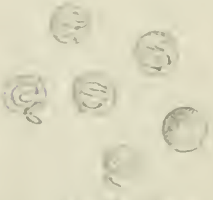

Fig. 7.—Corpuscular bodies containing flagella.

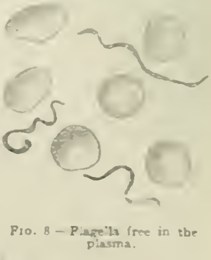

Fig. 8.—Flagella free in the plasma.

had stood for some time. I was not able to see in any of the specimens a cell with three or more flagella attached, and these flagella moving out free their full length from the cell. As soon as a flagellum pushed out from the cell wall, it seemed free by itself in the blood plasma and separate from the original cell. Whether the flagellum has the power or function of fructifying the other round cell or not, as in the case of malaria, I cannot say. I must say that, although I have searched diligently for these flagella in first attacks, I have never succeeded in running across them. More diligent search and other or better methods might, however, reveal their presence. The best specimens I saw were in blood obtained from a severe third attack, and the cover-glasses were moistened by the breath before touching them to the blood drop, as advised by Manson, in searching for flagellated forms of the malaria parasite.

It may not be absolutely proven that this hæmatozoon is the cause of the dengue, but its constant presence in the red blood corpuscle during the fever, its resemblance to the parasite of the Texas cattle-fever, its likeness in manner of growth and mode of propagation (by the mosquito) to the malaria parasite, all point in the same direction and lead us to believe by analogy, if by no other way, that in this parasite we have the cause of the dengue.

In conclusion, it is interesting that the culex should be found capable of carrying disease in man. Certain forms carry the proteosoma of birds, but I know of no disease they carry in man unless the form of mosquito which has been found to carry yellow fever be a real culex, and not a genus (stegomyia) by itself.

TREATMENT OF VESSELS FROM YELLOW-FEVER PORTS.*

A REPLY TO DRS. REED AND CARROLL.

By EDMOND SOUCHON, M.D.,
NEW ORLEANS, LA.
PRESIDENT OF THE LOUISIANA STATE BOARD OF HEALTH

I HAVE recently read over again the captivating article of Drs. Reed and Carroll in the MEDICAL RECORD of October 26, 1901,[1] entitled "The Prevention of Yellow Fever," and while admitting that mosquitos may transmit yellow fever, yet I cannot let go unchallenged several of the conclusions they reach under the heading of "Measures Directed Against the Importation of Yellow Fever Into the United States." They are as follows:

I.—"Under the admirable system of inspection and reports, as carried out by the Marine Hospital Service, the appearance of yellow fever at any foreign port is promptly reported for the information of the health authorities of our several Atlantic ports. We may, therefore, divide foreign ports within the so-called epidemic zone into (*a*) infected, and (*b*) non-infected ports."

"We believe that no quarantine restrictions should be placed upon either passengers or cargo from non-infected ports."

Now, many of those ports have no medical inspectors of any kind. Besides, all the men with any practical experience of these matters know how difficult it is for the medical inspectors of the United States Marine Hospital Service and of the Louisiana State Board of Health to ascertain reliably the true conditions of all the Mexican, Central and South American ports. The physicians and the people there are not afraid of yellow fever, and do not report it. It is only when cases are too glaring that the Louisiana and United States officers learn of them. Besides, almost all of these ports hold free and unrestricted intercourse with other ports, infected or non-infected. They ignore profoundly modern scientific sanitation; they practise no disinfection, and take no precautions whatever against anything or anybody, mosquitos or any other bodies.

Almost all the medical inspectors of the Louisiana State Board of Health, stationed there every year for many years past, report this. Therefore, how can we consider so-called non-infected ports as safe ports?

The Louisiana State Board of Health, by placing marine medical inspectors on board of vessels carrying passengers from fruit ports,[2] has almost done away with quarantine detention. The principal duty of the marine medical inspectors is to take the temperatures of every one on board in the evening, and to keep a clinical record with urine analyses of all the cases of fever, ever so slight, which may occur in transit.

Thus the vessel is truly a moving detention camp on which all on board are serving their probation time.

Vessels without any suspicious records are given credit for the number of days in transit.

The passengers which have been less than five days in transit are detained only a day or a day and a half so as to make five days.

The passengers on these vessels which have been five days in transit are not detained at all upon arrival at the Mississippi River Quarantine Station.

Passengers after disinfection are permitted to come on board as soon as the fruit vessel arrives at the fruit port, and their time of detention begins from that moment, so that many passengers who have only been four days in transit, but five days on board, are allowed to pass without detention at the Mississippi River Quarantine Station.

The fruit vessels themselves are not detained unless presenting suspicious or positive signs of sickness.

II.—"If the disease has developed *en route* among crew or passengers, the sick should be promptly removed; the forecastle or staterooms, as the case may be, thoroughly disinfected with sulphur or formaldehyde gas, and the vessel allowed to proceed to her wharf."

The following cases show how dangerous that practice would be, since they show that after one case has developed another may follow one day or more after. Besides, in the histories given below, disinfection had been practised before any case at all developed:

1880. Bark *Excelsior*. Sailed from London February 17, 1880. Arrived at Rio April 13. Left Rio May 10. Arrived at Mississippi River Quarantine Station June 25 (Wilkinson), having been on the voyage forty-five days. No case of sickness occurred at Rio or on the voyage. She was disinfected on June 26 and following (Wilkinson). She was detained twelve days altogether, up to about July 4. Arrived at New Orleans on July 5. On July 7, at 8.30 P.M., John Kinney was taken sick. On July 10, in the morning, he was removed to Touro Infirmary. He developed a genuine case of yellow fever. He died. The bark was returned to the quarantine station on July 10. Three more cases developed after the return at the quarantine station. Two died.[3]

1900. Non-infected Norwegian steamship *Bodo*, from Bocas del Toro, five days out, cargo fruit, living quarters and effects disinfected and vessel allowed to proceed to Middle Bay-Light, six miles below Mobile to discharge cargo into lighters. Vessel returned to station in forty-eight hours with one case of yellow fever, remanded to Ship Island Quarantine, where two additional cases developed later; no deaths.[4]

1900. Steamship *Electrician*, Belize, via Colon, Vera Cruz, and Tampico, three days out from Belize. Arrived at Mississippi River Quarantine Station October 7, and disinfected same day. On the 8th, three cases of fever developed. On the 11th three cases, and on the 12th one case—seven in all. Cases were all well marked but all recovered. A convalescent second-class passenger taken on board at Colon was the probable cause of infection.[5]

---

* Read at the meeting of the Louisiana State Board of Health of January 4, 1902, and officially approved by resolution of the board.

These vessels, if treated according to Drs. Reed and Carroll's theory, would have carried infection into a Southern port.

III.—"If more than twenty days have elapsed during the voyage without the occurrence of yellow fever, we see no good reason why either passengers or vessel should be detained."

The following cases of vessels more than twenty days out developing yellow fever, and that after disinfection, will surely convince the reader that assertions have no value in these days of modern science, which requires proofs for all assertions.

1890. British steamship *Curaca*, from Rio, with rock ballast. Sixty-eight days out from Rio. No sickness was reported at port, en route, or on arrival. Cleaned July 22 to July 23. Disinfection completed July 25 in the afternoon. One and a half days after completion of disinfection, one case of yellow fever developed July 27, in the early morning, before day. The disease was probably contracted between July 22 and July 25. Incubation between five days and one and a half days.[7]

1890. British ship *Chippeua*, from Rio, with rock ballast. Sixty-four days from Rio. No sickness was reported in port, en route, or on arrival. Cleaned July 26 and 27. Disinfection completed July 26. One day after, one man, the quartermaster, developed yellow fever at night. He probably contracted the disease between July 27 and 28. Incubation three and a half to one day.[8]

IV.—"With our present knowledge of its propagation, personal baggage should no longer be subjected to disinfection, and, with our increased ability to prevent its spread by measures easy of application, instances should be few and exceptional when a vessel coming from a yellow-fever port should be delayed longer than will be necessary to remove her non-immune passengers who have not yet completed their period of five days since leaving the port of departure."

We do not say that fomites will always carry infection, but we do believe that they can do so. We are most willing to be convinced, but we can only be convinced by facts well established.

The following cases stand before the distinguished writers for an explanation. I will confine myself here to cases reported by American writers, and will leave out the array of cases reported at the Geneva Congress in 1882, or in the works of Berenger Feraud, the French authority on Tropical Diseases, in which the intermediation of mosquitos seems impossible or superfluous:

1. Case at Franklin, La., in 1853:

Centerville, a small village on the Bayou Teche (having instituted no quarantine regulations), was swept by a terribly fatal epidemic.

The large village of Franklin (but five miles distant), having maintained a most thorough and effective quarantine, from the first breaking out of the disease in New Orleans, had remained entirely exempt.

On the evening of the 9th of October the physicians of Centerville notified the Mayor of Franklin that they considered the epidemic at an end, "as no fresh case had occurred during the last ten days." Intercourse between the two places was, consequently, permitted on the following day (the 10th).

Quarantine against Centerville was re-imposed by Franklin on the morning of October 11, on account of six new cases of fever reported on the night of the 10th.

On October 10, while quarantine was suspended, a merchant of Franklin received from Centerville certain goods, which, after being boxed up there, were opened at his store in Franklin in the forenoon of October 11, the merchant himself, with his three daughters "standing near as it was opened," and no one else present.

On October 16, between 1 and 6 A.M., the merchant and two of his daughters were seized with yellow fever, which resulted fatally for the merchant and one daughter. The third daughter had the disease later, with black vomit, but recovered.

So far as has ever been ascertained, this was the only direct communication between the two places during the cessation of quarantine.

No other cases occurred in Franklin that year.[10]

2. Case at Franklin, La., in 1854:

Again, Franklin, neglecting the enforcement of quarantine in 1854, was desolated with yellow fever, having permitted a steamboat direct from New Orleans to land and remain at a central wharf, some of her crew being sick with yellow fever at the time.

During the height of the epidemic a certain lot of household goods (blankets, quilts, and woollen and cotton stuffs generally) were packed in air-tight boxes for the purpose of being transported to Texas. For some cause they were not removed that season, remaining thus boxed up until the following November (1855).

The boxes remained during the winter in a room where a fire was kept. About the middle of November, 1855, Mrs. C. arrived in Franklin, intending to remove the above-mentioned goods, together with other property to her home in Texas. She concluded to repack the articles into larger boxes, and was engaged, during the greater part of two days, in opening the original packages and repacking them. On the night of the fifth day, from the time of commencing unpacking, she was taken with fever which terminated fatally, black vomit and suppression of urine supervening.

No other case occurred in or about Franklin that season (1855), save that of a man brought from Marksville (where an epidemic existed). The man was in a dying condition when landed—was buried the following day, and no communication could be traced between the two cases. The above case was peculiarly interesting to the attending physicians, happening as it did long after several frosts and even a solid freeze.[11]

3. Case at Pattersonville, La., in 1857:

Again, during 1857 (in September), a young man made his way from New Orleans, where yellow fever was prevailing, to Pattersonville, a small village near the mouth of the Bayou Teche. A very strict quarantine was being enforced throughout the parish (St. Mary), and this young man was consequently compelled to travel in a somewhat clandestine manner. He arrived at a store in Pattersonville some time after dark (the clerk was an intimate friend), and requested permission to remain all night, as he was too much fatigued to continue to his home some four miles farther. Permission was readily accorded. On retiring, he deposited at the foot of the bed a bundle, tightly corded. This bundle consisted of a heavy overcoat and a thick blanket. It had not been unrolled since he had wrapped it up in New Orleans (in a house, too, not only in an infected district, but wherein some cases of yellow fever existed at the time). During the night, the clerk (Mr. R.), feeling cold, intimated his intention of getting up "to procure more cover," when his bedfellow remarked, "I have just the thing for us," and reaching forward, untied the bundle and drew the blanket and overcoat over them both, under which they slept until morning. About one week (?) subsequently Mr. R., the clerk, was taken with yellow fever, dying on the fifth day with black vomit, and suppression of urine. There was no other case that season in the parish.[12]

4. Case of Mrs. F., St. Mary Parish, 1866:

In October, 1866, Mrs. F., a young wife of but a few months, was taken ill with a fever. She had been subject to somewhat frequent attacks of fever, which, though smart, had always been ephemeral. Her physician considered this as of the same character, but she insisted, from the first, that it was a different fever from any she had ever before suffered from. She died on the fourth night, with all the characteristic symptoms of yellow fever.

Here was a person living on a plantation, far remote from any town or village, and from which she had not been for weeks (two months). There had not been a case of yellow fever in the entire country, outside of New Orleans, and yet she unquestionably died with yellow fever. The husband (Mr. F.) afterward informed me that about a week (five days) before his wife was attacked, Mr. P. (a very intimate friend) had arrived from New Orleans.

The boarding house in which Mr. P. had logded while in the city was situated nearly in the center of the infected district, in the French part of the town. Three fatal cases occurred in the house itself during his stay. His trunk remained open in his room until the morning of his departure, when he locked it. It was not again opened until Mrs. F. unlocked it, for the purpose of taking out some articles of dress which Mr. P. had purchased for her in New Orleans.[13]

5. Case of child near Franklin, La., in 1867:

Again, during the summer of 1867, a most stringent quarantine was enforced by the authorities of Franklin (as well as by the other small towns situated on the Bayou Teche) against all persons, boxes, bales, and packages of every description arriving from New Orleans.

Mr. C., a planter, residing on an isolated plantation some twelve miles from Franklin, drove into that town one day during the latter part of October, 1867, and brought, among other purchases, a bale of woollen blankets. On his return home in the evening he took with him a little nephew (seven or eight years of age) that he might spend a few days in the sugar house, it being the "grinding season."

He slept with his nephew, and during the first night (the weather suddenly becoming cold) he arose from bed, undid the fastenings of the bale of blankets, and threw a pair over the boy, wrapping him well up in them. The fifth day afterward, the youngster was taken so ill that Mr. C. took him home in his carriage. The disease proved to be yellow fever, and terminated fatally.

This was a most puzzling case to the physicians for more than a year; not the slightest exposure to yellow-fever infection could be traced. It was finally discovered that the bale of blankets purchased by Mr. C. had not only come direct from New Orleans to Franklin about a week previous to Mr. C.'s buying them, but had lain all summer in a store in the city, located right in the middle of the infection.

These blankets, together with other goods, had been allowed entrance to Franklin on the statement that they had come direct from New York in a steamship which loaded at Algiers, the goods being transferred immediately from the steamer to the Opelousas cars.[14]

6. Case of Harry Beal, Cypremort, La., 1879:

The first case of sickness of a suspicious nature was Harry Beal, white, adult, native of the parish. He kept a store. He was taken sick on the 17th of October with fever, nausea, headache, and pain in limbs. He was seen by a physician for the first time on October 19, was restless, but free from fever; eyes injected, considerable nausea. Nausea increased and vomiting occurred. On the 22d he had several black passages from his bowels, and while straining in the effort to vomit, spat up some blood. Black vomit then occurred and the suppression of urine. He died October 25, in convulsions.

Investigation as to the cause of his attack has elicited the fact that he had received, on the 13th inst., a box of goods from New Orleans containing two dozen blankets of a very low grade. These were immediately unpacked, and their offensive smell was remarked by several persons who visited his store. After his death, these blankets were replaced in the box in which they arrived, saturated with coal oil and burned.

The next case occurred at a house just across the public road opposite Beal's store. Miss J. D. was taken sick about the same time Beal was attacked, but was not seen by a physician until October 20. She died October 21, exhausted by profuse hemorrhage from the womb.[15]

7. Case of Mr. C., Bayou Bœuf, La., 1879:

The first case of sickness was in the person of Mr. C., adult, white, who visited Morgan City about the 5th of September, and returned home on the 10th. He brought with him from Morgan City some second-hand bedding and clothing, and a few days subsequently was attacked with the disease. His family, wife and children, were soon down, but all recovered. Persons who visited his house were next attacked, and the disease spread rapidly in the little settlement.[16]

8. Indianola, Texas, incident:

The schooner *Margarita* sailed from Vera Cruz on the 11th of May, and came to anchor in the port of Indianola on the 21st of the same month. A Mr. Delord, a passenger on board, had a lot of second-hand blankets which were disposed of at auction, to which was attributed the rapid spread of yellow fever. The first cases were a drayman named Hunter, and a lad named Cook, who hauled the blankets to the place of sale. A Mr. Andrews certified that he, together with a Mr. Duke, examined the blankets at the auction room on the 25th of May. Three days subsequently he left for his home on Hynes Bay, and the same evening was attacked with fever. His companion, Mr. Drake, was attacked the day afterward, and in a few days died.[17]

9. Case of Mr. Lane of Milton, Fla., 1853:

Dr. Hulse of Pensacola, Florida, reported the following instance:

In 1855, a Mr. Lane was attacked with yellow fever at Dr. Fisher's, in Milton (which is a few miles from Pensacola). His effects were packed in a trunk, which was locked, placed in a storehouse, and covered with old cloth and sacks. In the summer of 1855, two years later, this trunk was sent from Milton to Brooklin in Alabama, forty or forty-five miles north, and it was opened in a house in presence of several persons. Soon after, six of those living in this house sickened, and several died with black vomit.[18]

10. Case of Mrs. C., near Taylor, Miss., 1898:

Dr. J. A. K. Birchett, State Health Officer at Taylor and Orwood, Miss., during the 1898 epidemic, reports the two following cases of infection by fomites as having fallen under his observation:

I visited the Gray House, midway between Taylor and Orwood, and found Mr. McC. confined to his bed with an attack of yellow fever. About September 15, he packed the clothing worn at the Gray House in a valise, and proceeded to his home, about ten or twelve miles distant in an isolated spot. On October 13, his wife removed the articles from the valise, and hung them out for an airing. On October 16, at 3 P.M., she sickened with an attack of yellow fever.[19]

11. Case of Miss A. B., near Taylor, Miss., 1898:

Miss A. B. attended the funerals of Dr. G. and H. W. on August 10 and 11, at which time she was clad in a woollen dress, which she took off and placed away in a closet on her return home. She was exposed to a case of yellow fever. About September 20, she was renovating the house, and removed the clothing (the woollen dress among other things) from the closet to air them. She was taken with yellow fever at 7 P.M., September 25. The isolation of these premises had been perfect, it being dangerous to attempt an approach to the house, as my driver can testify; he was shot while attempting to cross a portion of the place.[20]

12. Case at Jacksonville, Tenn., 1878:

In the history of the yellow-fever epidemic in 1878, by J. M. Keating, are mentioned a good many instances of fomites infection, several of which will bear relation:

At a meeting of the Davidson County Medical Association, Dr. Drake of Nashville reported the following cases.

At Jacksonville, Tenn., in 1878, a gentleman returned from Memphis, and, upon reaching home, hung his clothes in a wardrobe. After several days his wife took the clothing out. We would suppose that in a close, hot room the poison would multiply itself in this time until the air would be heavy with it, and so it seemed in this case, for the lady took the yellow fever and died, followed in due time by the rest of the family. The husband developed the disease only when confined to the house, ministering unto the sick.[21]

13. Case of Mrs. Vincent, at Houston, Texas, 1864:

Dr. T. J. Heard of Galveston, Texas, is quoted as follows:

About December 1, 1864, Mrs. Vincent, sister of Ex-Lieutenant-Governor Anderson, fled from Houston on account of yellow fever. A negro left behind took the disease, and as there was great lack of blankets, an old carpet was used instead. Six weeks afterward, Mrs. Vincent returned, and going in the garret took the carpet out to air it. Four days after this she had a most violent attack.[22]

14. Case at Covington, Tenn., 1878:

Keating reports on the source of infection at Covington, Tenn., as follows:

The only person who had the fever at Covington, Tenn., in 1878, was the postmaster, who received and opened a heavy mail that had been detained in the Memphis post-office for some time. In three days he died of yellow fever.[23]

15. Case at Bay St. Louis, Miss., 1875:

Statement of Dr. C. Delery of Bay St. Louis:

Says the malady originated in a house owned by a man named Martin. This house was inhabited by the Gallagher family. . . . This family arrived in Bay St. Louis from the State of Missouri last February. Since that time they had never left the bay, nor had they received any merchandise from the city or elsewhere. On the 23d of August a colored man named Williams arrived at the Bay from Pascagoula, which place he had left to escape the epidemic. He moved on the same day of his arrival into a room situated about thirty yards from the Gallagher family. The child, Myron Gallagher, aged six, went every day to visit Williams, with whom he passed part of the day. This child was the first to fall sick on the 31st of August, that is to say, eight days after his first visit to Williams.[24]

16. Cases near Summit, Miss., 1878:

The great yellow-fever epidemic of 1878 in New Orleans began in July. During that month Charlie and Louis W., sons of Dr. W. of New Orleans (then in Europe), had a fever, classed as malarial by the attending physician, who advised their mother to take them to the country to recuperate. That physician subsequently admitted that these two cases were yellow fever. On July 28, Mrs. W.

arrived with her children at the house of her father, Mr. Griffin, [illegible], Miss., on the I. C. R. R., [illegible] miles north of New Orleans, bringing with her baggage. Her trunk arrived the next day, July 29, and up to August 9, was only opened a few times by Mrs. W. to obtain such articles as she chanced to require, being immediately closed again. On August 9, having been invited with her children to visit her brother's home, some miles distant, Mrs. W. unpacked her trunk, spreading the contents on the bed, etc., and selected what she required for the visit. Returning immediately, she left the remainder of the clothing to be repacked by the [illegible]. The next morning, Saturday, August 10, Aleck Griffin, aged thirteen years, repacked the clothes, stooping over the trunk and handling each article. His mother, with her little daughter Mary and her son Whit and friends, were present and assisted. On August 13, the fourth day after the unpacking of the trunk, Aleck was seized with yellow fever, had black vomit August 20, and died August 21. On August 14 Frank was taken with yellow fever. He recovered. On August 14 Mary was taken at daylight and died on August 21. On August 15, Whit was taken about noon. He recovered. Mrs. Griffin was ill on August 14 but held out until the next day. She also recovered. Thus, every one of the five persons present at the repacking of the trunk were seized with yellow fever within five days afterward. The most important witnesses of these tragic events are living, and can be called on to testify.[25]

17. Case in Floating Hospital on Lower New York Bay, 1862:

During my services as Medical Superintendent of the Floating Hospital in the Lower Bay of New York, in September, 1862, I was sent for by one of my colleagues of the Brooklyn Hospital for consultation in a suspected case. I found there an unequivocal case of yellow fever. The patient died the third day thereafter. She was the widow of a seaman who had died in New Orleans two or three months before, whose clothing she had received and washed four days before she was taken sick.[26]

18. Case of Dr. Wm. Johnson, Surgeon United States Navy, 1860:

On the termination of a cruise on the west coast of Africa, some years before, when yellow fever occurred on board the ship to which he was attached, he packed his books in a barrel, and in that condition left them for about three months after they had been received and his arrival home. He then proceeded to unpack them, and three or four days thereafter he was taken with yellow fever, and came near dying.

19. Yellow fever in Madrid, Spain, 1879:

Dr. Guichet, surgeon in the French army, charged by the government with a special scientific mission in Spain, officially reported, in 1879, the following facts:

Madrid is 2,214 feet above the sea. In 1878, a number of soldiers, returning from Cuba, had been discharged because the insurrection had terminated. All of these at Madrid were apparently acclimated; certainly none came with yellow fever, nor had it while there. But a number of young people who lived side by side with these soldiers, and their clothing, trunks, and baggage, were attacked. The epidemic was restricted to a very few squares adjacent to the crowded domicile of these soldiers, beginning September 15. It was ended by October 15. There were twenty-five cases perfectly well known, but, according to the most authoritative medical statements, there were more than fifty sick, with about thirty-five deaths.[28]

20. Case of recrudescence at Edwards, Miss., 1898:

Edwards, Miss., is an illustration of a recrudescence, a few cases occurring in September, 1898, following the epidemic of the year before.[29]

21. Also at Memphis, Tenn., in 1879, after a freezing winter in 1878–79.[30]

22. Also Franklin, La., in 1898.[31]

Also New Orleans, La., in 1898 and 1899, after a freezing winter in 1898–99.[32]

23. Case of a frozen vessel, North:

I will cite another case illustrating the vitality of the poison of the disease. A small vessel in the tropics had had yellow fever on board. She was sent North in the fall of the year, and sunk in a Northern river. When the winter came on, the vessel was frozen in, or submerged in icy-cold water all winter. In the spring she was pumped out and raised, after a time put in commission, and sent again to a warm climate. Upon getting into the warm belt, and before making a port, the disease reappeared.[33]

24. Case of steamer *New World*, 1852:

I ascertained that about the middle of the year 1852, the steamer *New World*, after having lost more than half her crew by yellow fever in Rio, on her way to California, touched at Callao. The steamer *[illegible]*, during the same season, lost several of her crew there, proceeding to the Pacific, and arriving at Callao in April, 1852. Soon after her arrival, a mild form of a peculiar fever broke out in Callao and Lima, which the natives called "[illegible]," similar to the precursory fever which prevailed in Rio in 1849, it was called "polka." In both instances the disease speedily developed yellow fever. And considering the voyages, in connection with the continued presence of mosquitoes on board ship, it is hardly conceivable that they had anything to do with either its introduction or transmission.[34]

25. Case of the United States Frigate *Susquehanna*, 1857:

This ship, after more than two years' service in the Mediterranean, October, 1857, was ordered from Spezzia to San Juan de Nicaragua, where she arrived early in December, having touched by the way of Genoa, Madeira, and Key West. She remained at San Juan until the first of the following April, having had during the whole period of time she lay there a constantly increasing sick list of a "precursory" fever. At first intermittent, then remittent, but all recovered, until March 20, when a case became malignant with symptoms of yellow fever, and died; other cases followed. The ship put to sea April 1, and on April 5 arrived at Port Royal, Jamaica, with one hundred and six officers and men down with yellow fever. Most of these were sent to the hospital, and on the third day afterward she sailed for New York, where she arrived April 15, with fifty-one cases on the sick list.

The remarkable feature in this instance is that at San Juan, where the yellow fever first appeared on board the *Susquehanna*, there was no yellow fever, and the disease had never been known to occur there. As before stated, she had been more than two years on service in the Mediterranean, but with no extraordinary sickness on board. She had had yellow fever on board during service in the Gulf Squadron the summer before she was ordered to the Mediterranean, nearly three years before, and was supposed to have been thoroughly cleansed before she was ordered to the Mediterranean station.

But, as the sequel shows, she still retained the germs of the disease (or mosquitoes?) until she returned to the conditions of the yellow-fever habitat at the port of San Juan.

It is conceivable that the advocates of the exclusive instrumentality of the mosquito in her case may contend that she might have shipped the culex when she touched at Key West. But there was no yellow fever there at the time, and no case intervened between that time and the first unequivocal case on board the *Susquehanna*, March 20, after several weeks' prevalence of a precursory fever—a not very unusual feature of yellow fever observed on other occasions, and prominently so at the first outbreaks of the disease in Rio and Callao.[35]

26. Case of United States steamer *Plymouth*, 1878:

The persistence of yellow-fever infection under conditions commonly fatal to mosquitoes is particularly well shown in the history of the United States steamer *Plymouth*. She first became infected at St. Thomas in the summer of 1878. In November following she was sent to Portsmouth, N. H., and about a month afterward to Boston, where she remained four months. Meanwhile everything was removed from the ship, the crew were transferred, and she was fully exposed to intense cold for a month, for ten days of that time in dry dock, with a temperature at times below zero. The water in the tanks was frozen, as it was in cans put in the storerooms of the ship, and for several days after the fires were rekindled on board the cold continued so intense that the water froze in the bilges at night. One hundred pounds of sulphur was burned below decks, the fumigation extending over two days; the berth deck, holds, and storerooms were thoroughly whitewashed with a mixture of lime and chloride of lime.

March 15, 1879, she left Boston for a cruise in the West Indies. On the night of the 19th, in a severe gale of wind, the hatches had to be battened down, and the berth deck became very damp and stuffy. On the morning of the 22d (she had not touched at any port) Richard Saunders, machinist, was sick, but did not report until afternoon, when he had violent headache and fever. During the night of the 22d, Peter Eagan, boatswain's mate, was taken suddenly and violently sick with the same symptoms. On the 23d, at sea, latitude N. 27° 48', longitude W. 57° 59', the surgeon (Woolverton) reported both cases yellow fever, and recommended that the ship proceed no further on that cruise. The first case recovered; the second died on the third day of illness. The ship's course was changed to northward, and she arrived at Portsmouth, N. H., April 7. No new case appeared after she turned. "I am convinced," said the surgeon, in his report, "that the fever infection is confined to the hull of the ship, and especially to the unsound wood about the berth deck; and that while the *Plymouth* is a safe and healthy ship in a temperate climate, she cannot, for the present, be sent into a tropical climate without the certainty of an outbreak of yellow fever occurring on board; and that no precautionary measures whatever could avail to avert such a result."

Soon after her return to Portsmouth, April 7, she was surveyed by a board of medical officers, who reported that: "After careful consideration of all the facts, we have arrived at the conclusion that the infecting virus which gave rise to the last outbreak of fever must have been preserved in the rotten wood of the berth deck or in the bedding or clothing of the crew."[36]

27. Case of United States ship *Vermont*, 1878:

July 12–18, 1878, yellow fever broke out on board the United States ship *Vermont*, at the Brooklyn Navy Yard, of which there were eight cases, with three deaths. According to the investigation and report of a board of medical officers of the navy, "the disease seems to have originated from the ballast of the bark *Juanita Clar*, which left Havana May 1. This ballast, quarry clippings and sand, was deposited on the dock on either side of the *Vermont*, and about one hundred yards distant from her.

On this report, the ballast was promptly disinfected and covered over with fresh earth, after which there was not another case.[37]

V.—"The chief duty of quarantine officers hereafter will consist in the detection of mild or very mild cases of yellow fever. In a series of twelve cases of experimental yellow fever produced by the bite of *stegomyia fasciata*, we have, elsewhere, pointed out that four, or 33 per cent., were mild or very mild in character, and have indicated the difficulty of making a positive diagnosis of such cases."

We quite agree with Drs. Reed and Carroll, but how is the quarantine officer to diagnose light cases which run their course *en route* in three or four days, without even putting the patient to bed, and which, nevertheless, we consider have infected the vessel?

The Louisiana State Board of Health has solved that problem by compelling regular vessels with passengers from fruit ports to carry a marine medical inspector whose principal duty as explained above is to take the temperature of all on board in the evening, and to keep a clinical record with urine analyses of the cases with the least fever occurring during the voyage.[38]

VI.—"In discussing the period of incubation of experimental yellow fever, we have shown that in 16.6 per cent. of our cases the period of incubation exceeded the usual quarantine period of five days. If we add Carter's cases to those observed by ourselves, we find that of twenty-four cases the period of incubation exceeded five days in three, or 12.5 per cent."

The number of cases cited is too small to justify such conclusions. If the risk was 12 per cent., I am satisfied that the Louisiana State Board of Health and the other State boards would at once adopt a six days' quarantine. But the following figures, on a much more gigantic scale, prove that five days is long enough. That some cases may exceed five days, we readily admit, but think the cases are rare and the risk very small. We must accept small risk or destroy commerce; but even in accepting them, we believe in surrounding them with all possible safeguards.

The following is the basis of the five days' quarantine of the Louisiana State Board of Health.[39]

In 1897 and 1898, tons of merchandise were shipped from infected localities under the Atlanta regulations to non-infected localities without carrying the disease.[40]

From 1881 to 1895, 2,307 vessels were quarantined at the Mississippi River Quarantine Station. Of these 2,307 vessels, surely 98 per cent. came from tropical ports liable to yellow fever; 65 per cent. came from ports actually infected with yellow fever, 33 per cent. came from ports liable to yellow fever, and 2 per cent. from ports infected with cholera. Of this number quarantined and disinfected, 2,307, yellow fever appeared subsequent to disinfection on three only. No case of fever developed after the third day.[41]

There were passed 1,007 people through Camp Hutton, near New Orleans, in 1897. There was turned back and sent to the Isolation Hospital of the camp one man with yellow fever who was applying for admission. There developed in camp three cases of yellow fever, but one of these was doubtful. The cases developed within forty-eight hours after entry.[42] No case developed in any one leaving the camp (Dr. H. R. Carter).

At the Oakland Park Detention Camp in New Orleans, in 1897, there were in all 237 admissions, all from houses in which yellow fever existed. Five inmates developed yellow fever at the following intervals after admission. One case on the second day, two on the third, one case on the fourth, and one case on the fifth. None infected any of the attendants, nor any of the inmates of the camp.[43]

There were passed through Camp Fontainebleau, in 1898, from McHenry, eighty-four people, and from other points along the coast, 323. There was no case of yellow fever in the camp in 1898.[44]

The experience of the Mississippi River Quarantine Station and of the Detention Camps is that cases of yellow fever develop within five days after disinfection.

In 1898 there were sent 500 negroes to Camp Haralson from Oxford, Miss. These negroes came from all sections of the town, many of them from infected houses. No disinfection. Eight cases of yellow fever developed in camp. None after five days in camp. To another camp I sent fifty whites. No disinfection. In this camp three cases developed. None after five days away from Oxford.[45]

It may be said that some of the cases were infected many days before being removed, but this is an assertion without proofs which can be refuted in a like manner by an assertion without proofs.

For protection and for quarantine purposes, it suffices to show that no case developed after five days from the last exposure.

VII. In conclusion, Drs. Reed and Carroll make the following appeal:

"A most important part will have been accomplished if we can persuade the sanitary authorities of our sister Republic Mexico, and of the Central and South American States, to join us in the adoption of more enlightened methods for the suppression of this widely prevalent epidemic."

This is the keystone to the whole fortress of protection. Let these ports destroy all possible causes of yellow fever, and let them disinfect thoroughly before departure all vessels going to ports liable to yellow fever, or going to Northern ports which may transmit it to Southern territory, and we will be safe enough to alter our quarantine regulations.

Case of Symptomatic Epilepsy, Circumcision, and Complete Recovery.—Knox Bacon reports the case of a child of nine years, who gave a history of good health until March, 1901, when he began to have slight seizures, affecting principally the muscles of the left side of the body, and as the disease continued the entire muscular system was involved. In August, when first examined, he was having from eight to fourteen spasms in twenty-four hours. From the indications, circumcision was deemed advisable, and was performed September 1st. For twelve days following the seizures were as frequent as ever, but after that gradually lessened in number and severity. The child improved in weight and in general health and disposition.—*St. Paul Medical Journal.*

NEPHRECTOMY.—A CLINICAL STUDY OF FOUR CASES.*

By LOUIS J. LADINSKI, A.B., M.D.,

NEW YORK.

ADJUNCT PROFESSOR OF GYNECOLOGY, NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL; VISITING [illegible] TO [illegible] ISRAEL HOSPITAL.

Among a number of cases of surgical diseases of the kidney treated by me, I have selected for presentation this evening, principally from a clinical standpoint, a typical and interesting case of each of the four chief varieties, namely: (1) Calculus and pyonephrosis; (2) Tuberculosis; (3) New growth; (4) Suppuration.

Before reciting the history of these cases, I wish to say a word in reference to the clinical examination of the kidney.

The methods of examination of the kidney for the case requiring surgical treatment are inspection, palpation and percussion, by means of which we ascertain the size, mobility, contour and consistency of the kidney, and differentiate between a tumor of the kidney and that of other organs of the abdominal cavity.

Of the more absolute means of examination, the most important are catheterization of the ureters, for the purpose of collecting separately the urine of both kidneys, and of testing the patency of the ureter and renal pelvis, and cystoscopy, which demonstrates the condition of the mucosa of the bladder and the ureteral orifices. This is performed by means of the cystoscope of Nitze or its modifications, in the male, or that of Nitze or Kelly in the female. Catheterization of the ureters is not always readily accomplished, and at times is inadvisable because of the possibility of carrying infection from the bladder up into the ureters. In that case, the urine from the right and left ureters can be collected separately and at the same time, by means of Harris' segregator. My personal experience with this instrument, especially in the female, has been very satisfactory.

The *x*-rays have been used with success in a number of cases of renal calculus, but as a rule this method is not absolutely reliable.

The freezing test, or cryoscopy, is a test of the function of the kidney, and not of its structure; that is to say, that an organic or structural lesion of the kidney will not be detected by this test, but if part of the kidney be destroyed, as a result of some surgical disease, cryoscopy will determine if the remaining portion be functionating normally or not. It consists in comparing the freezing point of the blood or urine, in a given case, with the freezing point of the normal blood or urine, and is based on (1) Rault's Law, which is, as given in Remsen's chemistry, "One molecule of any compound, when dissolved in one hundred molecules of a liquid, lowers the freezing point of that liquid by an amount which is nearly constant"; and on (2) Korany's theory of molecular exchange in the kidney tubules. The freezing point of the normal blood is 0.36° C. below that of distilled water; if the freezing point of the blood is lowered to 0.50° C. or below that, there is an impairment in the functionating power of the kidney. The freezing point of the urine is less reliable as a test, but when below 0.9° C. renal insufficiency is indicated.

When the methylene-blue test is used, the permeability of the pelvis and the ureter is ascertained by the time it takes for the appearance of the blue color in the urine, after the introduction of the methylene blue into the system, and the functionating capacity of the kidneys is estimated by the time required in the elimination of a given quantity of the methylene blue. By what is known as the florrizin test the functionating activity of the kidneys is determined by the rapidity of the appearance of glycosuria, after the administration of florrizin.

---

* Read at a meeting of the Eastern Medical Society, held November 9, 1901.

Of the utmost importance is a quantitative and qualitative chemical, as well as a microscopical and bacteriological, examination of the urine collected separately from each kidney; this will not only assist in arriving at a diagnosis of the nature and the seat of the disease, but by means of cryoscopy, and from a comparative estimate of the urea excreted, it will also be possible to determine the functionating capacity of each kidney.

The distinctive changes in the urine, accompanying the diseases mentioned, may be summarized as follows:

In calculus the urine is invariably acid, there are microscopical or macroscopical traces of blood and an excess of crystals of the salts composing the calculus. When there is an accompanying pyonephrosis, the urine is the same in character as that of suppuration.

In tuberculosis there may be no change in the urine in the early stages; in the advanced stages, varying quantities of blood and pus are found. When the process is an ascending one, pus is found long before there are any renal symptoms. Hyaline and granular casts, epithelial cells from the pelvis or tubules, may occasionally be found. The urine is acid early in the disease, but later it may become alkaline; the quantity of urine secreted is increased, especially in the early stages. The amount of urea is much diminished. Tubercle bacilli are not always found; it may require frequently repeated examinations to demonstrate them.

There are very few changes in the urine indicative of new growth of the kidney. Blood, principally microscopically, is found in the later stages; when the pelvis is involved, elements of the growth may appear in the urine. The amount of urine secreted may be increased or diminished. Urea, chlorides, and acid phosphates are, as a rule, diminished.

In suppuration, when the process is in the kidney proper, the urine is acid and purulent, and frequently contains blood; when the pelvis is involved, the urine is acid at first, but later it becomes neutral or alkaline, especially so if the mucosa of the bladder becomes affected. In the early stages the amount of urine secreted is increased; later, when abscesses form, and there is a destruction of successive areas of the kidney, the quantity is diminished. The albumin depends on the amount of blood and pus. Hyaline and granular, and infrequently pus casts are found. In the early stages of suppuration of the pelvis, pelvic epithelial cells are discovered. The amount of urea excreted is diminished.

The principal symptoms common to the varieties of surgical diseases of the kidney under consideration are: (1) Pain; (2) Hæmaturia and pyuria; (3) Tumor; (4) Frequent and painful urination; (5) Polyuria or anuria, and (6) Febrile condition. With tuberculosis and malignant growth, there are also constitutional symptoms, peculiar to these diseases. The differential points in reference to these symptoms are as follows:

Pain.—In calculus, in addition to the renal colic due to the passage of a stone into the ureters, there is pain due to the presence of the stone, which radiates into the pelvis, is paroxysmal in character, and is increased on exercise. In tuberculosis, pain is present as a rule, but is very slight. In new growth it is generally severe and radiates in all directions, and is not influenced by position. In suppuration of the kidney, pain is always present in a variable degree.

Hæmaturia.—In calculus it is not profuse, but microscopically is always present; it is usually coincident with attacks of pain. In tuberculosis, new growth, and suppuration it is occasionally present. Pyuria with acid reaction is found in pyelonephritis due to calculus, in tuberculosis, and in suppuration. Frequent and painful urination is always present in tuberculosis (in fact, at times it is the first symptom), and occasionally in calculus and suppuration. Polyuria is especially noted in tuberculosis. Anuria is due to an obstructing calculus.

Temperature.—In calculous pyelonephritis there is a slight elevation of temperature; in tuberculosis a characteristic evening rise, and in suppuration a continuous or intermittent high temperature.

CASE I.—Calculous Pyelonephritis.—S.E., eighteen years old, Hungarian, single, domestic. Family history, negative.

Menstrual History.—She began to menstruate when thirteen years old, four-weekly in type, moderate in amount, and painless. One year ago, she ceased menstruating for an entire year, but is again menstruating regularly.

Previous History.—She has always been in a delicate state of health.

Present History.—Five years ago she began to experience some discomfort in her left lumbar region. At times the discomfort would become quite aggravated and would be accompanied by vomiting, which lasted for a day or so. These attacks would recur at intervals of weeks or months; between the attacks, however, she was quite well. Two weeks prior to her admission, a rapidly growing tumor made its appearance in the left lumbar region, which was very painful and compelled her to take to bed.

On admission to Beth Israel Hospital, June 21, 1901, the patient looked very ill and complained of severe pressure pains in the left side; the cheeks were flushed and there was slight œdema of the eyelids; tongue was coated, but moist; heart, lungs, spleen, and liver were normal. Temperature 100°, pulse 84, respirations 24.

Inspection revealed a marked bulging of the left abdomen; on palpation a somewhat tender and fluctuating tumor was felt, occupying the greater part of the left side of the abdomen, and extending from the free border of the left ribs down to a point about two inches below the umbilicus, and reaching to the right of the median line. The tumor was somewhat irregular in form, and the center was the most fluctuating part. The overlying skin was normal.

The urine was turbid, acid, and free from sugar. Microscopically, a few blood cells and many leucocytes were found. Quantity secreted was very much diminished, but amount of urea excreted was normal.

June 24, three days after admission, patient began all of a sudden to pass large quantities of turbid, foul, purulent urine (48 ounces in four hours). This was followed by a great relief from the pain and tension in the lumbar region, and the tumor on the left side became simultaneously much reduced in size. Microscopically, the urine showed innumerable pus cells and round epithelial cells from the kidney.

Having been out of town, I saw the patient for the first time on that day, and diagnosed the case as one of pyelonephrosis. Next day, June 25, under ether anæsthesia, a transverse incision was made in the left lumbar region, and the kidney exposed. The kidney proper was found to be small, soft, and flattened out like the head of a mushroom, the pelvis, however, was enormously distended. An incision into it evacuated a considerable amount of purulent fluid. On exploring the pelvis of the kidney, no stone was found, but its walls, and that of the ureter, were very much thickened and intimately adherent to the neighboring viscera, its cavity extended on the inner side to the umbilicus, above to the free border of the ribs and below to the iliac fossa

Taking into consideration the extensive inflammatory process and the disorganized condition of the kidney, I decided that a nephrectomy would give the best ultimate result. As it was impossible to remove the kidney and its pelvis en masse, the kidney was first removed after having tied the renal vessels, then the walls of the pelvis of the kidney were separated from the adherent viscera, ligated in sections, and cut away. All bleeding was checked by compresses. The cavity, which was very large and extended down into the pelvis, was packed with gauze and dressed from time to time.

On the afternoon of that same day, the house surgeon, Dr. Rabinowitz, was summoned because the patient complained of some obstruction in the urethra, and extracted a mulberry calculus which he found protruding from the urinary meatus.

June 30. The amount of urine secreted since the operation, was on an average of 30 ounces daily. The last examination showed it to be clear, acid in reaction, of 1,024 specific gravity, with a slight trace of albumin, microscopically, a few pus cells, and a few bladder and pelvic cells were found.

August 14. She was discharged well. Temperature, 98.6°, pulse, 90, respirations, 24, with a sinus of about five inches in depth.

Note.—November 15. The sinus has since healed completely.

Microscopical examination of a section of the kidney showed an interstitial nephritis.

In this case the presence for so long a time of the calculus in the pelvis of the kidney, and its interference with the outflow of the urine, by its action as a ball valve, has resulted in the enormous distention, inflammation, and hypertrophy of the pelvis, and in the degeneration of the kidney.

It conclusively proves the necessity of an early operation for calculus when the diagnosis is established.

CASE II.—Tuberculosis of Kidney. L. N., thirty-three years old, housewife. Mother died of carcinoma of breast, father is alive and well. She began to menstruate when fourteen years old, four-weekly in type, moderate in amount, and painless. Married at the age of eighteen, and gave birth to three children; the first child one year after marriage, the last one ten years ago.

During her last confinement she was very sick, and about eight weeks later was operated on, her appendix and some tumor having been removed. Since the operation, excepting for sciatic pains, from which she has been suffering from time to time, she felt quite well up to one year ago.

About eighteen months ago, she began to suffer from frequent and painful urination, the pain being especially marked toward the end of urination. These symptoms have continued with varying intensity until the present time. Almost constant treatment for these symptoms afforded no relief. For the last year she suffered from headache, backache, and pains in the right lumbar region, radiating toward the pelvis. For some weeks before her admission, all the above symptoms became very much aggravated so that she had to take to bed.

On admission to Beth Israel Hospital, January 13, 1901, patient was fairly nourished, tongue was somewhat coated, but moist. On auscultation there was an occasional skipping of a heart beat, but no murmurs. Lungs, spleen, and liver were normal. The right kidney was felt to be movable and slightly tender on pressure. Temperature, 98°; pulse, 80; respirations, 22.

Urine was straw-colored and turbid, acid in reaction, and contained a slight trace of albumin, microscopically, an abundance of pus cells and a number of hyaline casts were found.

January 16. The urine was very turbid and acid, and there was a moderate trace of albumin; microscopically, innumerable pus cells, many hyaline casts, a few pelvic cells and kidney cells. No tubercle bacilli.

January 26. Under chloroform anæsthesia, the usual lumbar incision was made, and the kidney thoroughly palpated and explored. As nothing abnormal was found, nephropexy was performed.

January 31. Urine was straw-colored, turbid, about 20 per cent. of albumin by bulk, acid; microscopically, many pus cells, a few pelvic and kidney cells, and some hyaline casts, urea normal in amount.

February 7. The urine was less turbid and the number of pus cells much less than in any of the previous examinations.

February 22. The urine again became turbid, albumin about 15 per cent. by bulk, urea normal in amount, pus cells in abundance, kidney cells, and a few tubercle bacilli were found for the first time.

March 1. A cystoscopic examination, by means of Kelly's cystoscope, was made under spinal anæsthesia, and this revealed the mucous membrane to be greatly thickened, corrugated and congested, and some of the folds were bathed with pus.

March 15. The albumin in the urine began to increase, quantity of urine secreted and amount of urea was normal.

March 29. Since February 21 repeated examinations were made for tubercle bacilli, but none were found.

March 30. For the last four days, patient developed a dry, hacking cough, with evening temperature ranging from 103° to 104°, pulse 130, respirations 36; accompanied by night sweats and headaches. Mucous and sibilant râles and sonorous breathing were heard over both apices, and below the left scapula there was distinct bronchial breathing.

From the time of her admission, she had a daily rise of temperature, occasionally it would reach 105°; pulse was always rapid, and at times very feeble and irregular, and the general condition of the patient was gradually growing worse. The kidney was slightly increasing in size. The urine continued to be cloudy, and contained pus and kidney elements.

After having refused the suggestion previously, the patient finally consented to have a nephrectomy done. This was performed on May 28.

Macroscopical examination of the excised kidney showed the presence of many cysts of various sizes, the largest being that of a hazel nut, situated mainly near the cortex, and some of which were filled with cheesy purulent material. Microscopical examination showed these deposits to be tubercular.

The patient passed 20 ounces of urine the first twenty-four hours after the operation, and an average of 34 ounces daily, subsequently. The bladder was irrigated daily.

On July 24, 1901, she was discharged in a fair state of health, with a small sinus in lumbar region.

Temperature, 98°; pulse, 90, respirations, 24.

Note.—November 1. Patient has improved in health and strength, and has gained about twenty pounds. The wound has healed completely. Examination of urine made this week showed no tubercle bacilli, nor any abnormal elements.

Tubercle bacilli may reach the kidney through the circulation or the lymphatics, or by way of the ureters.

I am inclined to believe that the process in this case was an ascending one, judging from the fact that the patient has had a protracted vaginitis, urethritis, and cystitis long before there were any renal symptoms.

It is interesting to note that after frequent and careful examination of the urine during many months, both before and after operation, tubercle bacilli were found but once.

CASE III.—Adenoma of Kidney or Struma Suprarenalis.—Mrs. G., fifty-five years old, born in Germany, married thirty-eight years, has had five children. Family history, negative.

Patient was well until about three years ago, when menopause set in. Then she began to have attacks of hæmaturia. These attacks would occur every two or three weeks, at times she would pass about 3 or 4 ounces of blood. This condition lasted for about six months. She began losing in weight and strength.

About two years ago patient was very ill, and was then told (by a physician) that she had a stone in the kidney. The attack lasted three weeks. She was under treatment by various physicians, until she came under my observation.

I saw the patient on May 17, 1901, and found her very much emaciated, extremely anæmic and cachectic, with a weak thready pulse, and in a very poor and enfeebled general condition.

Physical examination: Heart and lungs normal; temperature normal; pulse, 80, and small.

Vaginal examination, negative.

Abdominal muscles were soft and flabby; a sausage-shaped mass could be distinctly felt in the left lumbar region, extending upward to the free border of the ribs and downward to the inguinal region. The lower border was free, round, and distinctly palpable. The tumor was immovable and tender to the touch; it was evidently connected with the left kidney, but at the lower extremity it appeared to be adherent to the descending colon.

Rectal examination revealed nothing.

I diagnosed the case as one of sarcoma of the kidney and advised exploratory nephrotomy. Dr. James P. Tuttle saw the patient at my request and concurred in the diagnosis.

Examination of the urine of each kidney, collected by Harris' segregator, showed the urine from the right kidney to be normal, and that from the left to be turbid, acid, and to contain a faint trace of albumin, and 2.5 per cent. urea; there were epithelium from the bladder and from the pelvis of the kidney, and granular, fatty, and hyaline casts.

The amount of secretion was about three times as large from the right as from the left. Cystoscopic examination by Kelly's instruments showed bladder mucosa to be normal.

I operated on the patient at her home on May 23, 1901, under chloroform anæsthesia, assisted by Drs. Tuttle, Luckett, and Goodman.

A transverse lumbar incision was made, the kidney was exposed and found to be very much enlarged, the capsule was considerably thickened, congested, and adherent. The lower pole of the kidney was occupied by a large tumor, which extended downward toward the pelvis. The growth was soft, very vascular, and friable, and bled profusely.

Isolation of the kidney and tumor was followed by severe hemorrhage, which could only be checked by compresses held by the assistants.

As the incision, though enlarged, did not permit of the removal of kidney and tumor at the same time, a ligature was placed around the renal vessels, a temporary ligature placed around the lower border of the kidney, and the kidney removed, leaving the tumor *in situ*. This permitted a clearer view of the growth, which was found to be intimately adherent to the descending colon, pushing the latter forward and toward the median line. The tumor was rapidly separated from the colon by blunt dissection and removed, bleeding vessels were ligated, and the profuse parenchymatous bleeding from the wall of the large cavity was checked by tight packing with gauze. The wound was partly closed by means of deep silkworm-gut sutures.

There was little reaction from the operation. For the first twenty-four hours after the operation pulse ranged from 78 to 96; temperature, 99° to 100°; respirations, 26 to 36; urine passed, twenty-five ounces.

May 25. Second day after operation, temperature, 99° to 100°; pulse, 72 to 88; respirations, 26 to 28.

May 26. Temperature, 99° to 99.6°; pulse, 72 to 88; respirations, 26 to 28; urine, twenty-seven ounces.

May 27 to 31. Temperature, pulse, and respirations, normal; urine averaged thirty ounces. Chemical and microscopical examination of urine, negative.

June 1 to 6. Condition same; urine, thirty to fifty ounces daily.

Cavity packed every other day, which gradually filled up, and healed over completely in about six weeks.

October 1. The patient has gained some thirty pounds since the operation. She looks better and is stronger than she has been in years.

Microscopical examination by Dr. F. M. Jeffries proved the growth to be "adenoma of kidney or struma suprarenalis."

Struma suprarenalis is a term given by Grawitz to that form of adenoma which is developed from a supernumerary adrenal inclosed within the capsule of the kidney. The true nature of this variety of tumor is still under discussion; it is considered by some as adenoma, by others as carcinoma, and still by others as sarcoma. While it is true that some authentic cases of struma suprarenalis have proved to be benign, and many have run a malignant course, both in reference to recurrence and metastasis, all observers are agreed that it is impossible to distinguish clinically or microscopically between the benign and malignant forms. The treatment, therefore, in every instance, should be early removal.

CASE IV.—Acute Suppuration of Kidney.—E. L., primipara, nineteen years old, married one year, last menstruation nine months ago.

Dr. Louis Friedman was called after she had been in labor thirty hours, with midwife in attendance; he found pulse and temperature normal, and applied forceps under chloroform anæsthesia.

Due to a deformed pelvis (contracted in all diameters), the extraction was difficult; no laceration of perineum, but slight laceration of cervix. Placenta was adherent and was removed. Slight post-partum hemorrhage.

Four hours after delivery, temperature rose to 102° F., pulse 110. The next morning temperature, 100°; pulse, 90. Intrauterine douche, 1-8000 bichloride. Bowels moved with calomel.

Puerperium continued without any rise of temperature or pulse for six days, but it was necessary to catheterize for retention.

On the afternoon of the sixth day, patient complained of pain in right lumbar region. Lumbar muscles were rigid and somewhat tender on pressure. On the evening of that day, temperature was 102°; pulse, 116. Uterus was contracted and not tender on pressure; lochia not fœtid. Five hours later a chill, lasting one hour. Temperature, 104°; pulse, 120. Seventh day, temperature in morning, 105°; pulse, 130; pain, rigidity, and tenderness of right lumbar region were more marked; no palpable tumor present. Temperature in evening, 106°;

pulse, 140. Patient was curetted, some small particles of placental tissue and adherent clots were removed. Morning temperature eighth day, 104°, pulse 120. Pain on right side increased. Still retention, urine found to be very ammoniacal, full of pus, blood and albumin. Temperature in evening, 106°; pulse 150. Stimulants and enemata of salt solution administered. Pain in right side increased, for the first time dulness on percussion in right lumbar region.

I saw her in consultation with Drs. Friedman and Lefkovits on the morning of October 23, the ninth day after delivery. Her temperature was 104°, pulse, 150, and irregular, respirations, 40. She looked sallow, and the muscles were flabby and skin œdematous. The tongue was moist, and mind perfectly clear. There was absence of delirium, and restlessness and anxious expression. There was only slight prostration. The abdomen was soft and flaccid, and free from any tenderness. There was a distinct sensitive tumor in the right lumbar region. It was immovable, and the lower border was rounded.

Vaginal examination revealed a slight laceration of the cervix. Uterus slightly enlarged but not sensitive, and containing blood clots. The adnexa and para- and peri-metrium were normal. I made a diagnosis of surgical kidney, in which the attending physicians concurred.

I had the patient transferred to my service at the N. Y. Polyclinic Hospital for immediate operation. Pulse on admission was 148 and very weak, temperature, 104.6°. Under chloroform anæsthesia, the uterus was first curetted, irrigated and packed, by my associate, Dr. Luckett.

The patient was then placed on the left side, and while she was being transfused with salt solution, a transverse lumbar incision was made. The kidney was exposed, it, as well as the tissue around it, was found to be œdematous. An incision was made into the pelvis, through the cortex of the kidney, and a quantity of bloody fluid evacuated. A gauze drain was introduced into the pelvis.

The temperature dropped after operation to 101°; pulse, though still rapid, was of much better quality, she passed 30 ounces of urine the first twenty-four hours, which was acid in reaction, and contained a large amount of albumin and pus cells.

During the following seven days her temperature ranged between 100° and 103°, and her pulse between 81 and 120. She passed on an average of 30 ounces of urine daily, examination of which on the seventh day proved negative.

The wound in the kidney was dressed every other day, the bladder irrigated with potassium permanganate solution, and high enemata of salt solution given at regular intervals.

On the eighth day after operation, I used the Harris segregator and drew off the urine from the left kidney, which, on examination, proved normal; no urine could be obtained from the right kidney, nor was there any discharge of urine from the wound.

Her condition for the next week continually improved, temperature and pulse were slightly above normal. As a microscopical examination of a section removed from the kidney showed purulent foci of pus, and streptococci and staphylococci, I decided to remove the kidney, which I did on November 6. The kidney was very much enlarged and œdematous and ecchymotic. There were several small abscesses in the cortex, near the lower border. The wound was closed by means of deep sutures, except for a small drain.

Note.—The patient made an uneventful recovery.

Infection may be communicated to the kidney, either through the circulation or by the lymphatic system, or by the extension upward of an infection from the vagina, urethra, etc. This is evidently a case due to the last named.

The interesting points in this case are: (1) The rapid extension upward to the kidney of the infection from the vagina. (2) The differential diagnosis between acute suppuration of the kidney and puerperal septicæmia. (3) The immediate and remarkable improvement following the incision into the pelvis of the kidney. (4) The comparatively little constitutional disturbance after abscesses had developed in the kidney.

[illegible] Madison Avenue.

Unrecognized Syphilis in General Practice.—L. Duncan Bulkley calls attention to the fact that syphilis is often unrecognized in general practice for the following reasons: (1) Syphilis is certainly not a venereal disease in all cases, and the absence of any history of sexual exposure should never throw one off the guard, when there is reasonable evidence of the existence of the disease. In addition to the large number of instances of innocent marital and hereditary syphilis, there are a certain number of cases of extra-genital chancre, which must always be reckoned on when confronted with possible syphilis. (2) Syphilis is often a very erratic disease and it is sometimes difficult to get a satisfactorily corroborative history. Not only may previous symptoms have been prevented or held in check by treatment, but even if left to themselves some of the early manifestations may be very slight and escape notice, yet be followed by serious lesions. This is particularly the case in women. (3) Many cases of unrecognized syphilis have very severe later symptoms, involving great destruction of tissue and severe lesions of internal organs. This is due to the absence of previous controlling treatment. It has been a common remark that syphilis acquired by means of an extra-genital chancre was apt to be of a very severe character. It is furthermore these cases which are often overlooked. (4) Syphilis is such an imitator of other diseases that its presence may often be suspected when they present unusual or peculiar features. In such cases, careful study and analysis will often serve to determine the true nature of the trouble, but it may be difficult to obtain a perfectly satisfactory corroborative history. In many instances of late syphilis from innocent infection the sufferers do not at all suspect the nature of their disease. (5) As many of the late, often unrecognized, lesions of syphilis are the result of imperfectly treated early syphilis, it is desirable that the general profession and the laity be thoroughly convinced of the necessity of careful and prolonged treatment to cure the disease. Too often syphilis is treated in a superficial and hasty manner, which is neglected as soon as the symptoms disappear. According to all modern experience and opinion, this is wrong, and physicians should see to it that patients receive proper treatment for at least two years, in the manner now accepted and fully described in writings on the subject.—*International Medical Magazine.*

The Agglutinating Power of the Serum in Bubonic Plague.—G. Polverini found that the agglutinating reaction of the serum is very marked in severe cases. In light ones it can be demonstrated only by the most delicate tests requiring long practice to be successfully performed. Even in severe cases it is not to be found in the first ten days of the disease. Plague being of easy diagnosis in marked cases, it is evident that this agglutinating property of the serum is of little assistance to the physician. It is of use in the diagnosis of diseases with a long course, such as typhoid or Malta fever, which may be confounded with other diseases, and in which this specific germ is not readily found, but of little value when, as in bubonic plague, the course is rapid, the symptoms well marked, and the specific germ easily found.—*Rivista Critica di Clinica Medica.*

MEDICAL RECORD:

New York, February 8, 1902.

IMPROVING THE HUMAN BREED.

To improve the human race, mentally and physically, has been the aim of philosophers at intermittent periods from time immemorial. During the past few years the matter has been again brought forward with much persistence, and various schemes —mostly impossible—have been suggested to attain this object.

The ancient Greeks would seem to have most nearly solved the problem, but as their system was based upon the principle of the survival of the fittest, a reversion to so cold-blooded a method would hardly be in keeping with the humanitarian spirit of the present age.

Laws regulating marriage are in favor with many, and are in force to a limited extent in a few States of this country. The close confining of criminals, and even their asexualization, are projects which have received consideration at the hands of some earnest anthropologists.

No plan as yet advanced but presents difficulties in the way of realization apparently insuperable.

Sir Francis Galton recently delivered the second Huxley lecture of the year at the British Anthropological Institute, and took as his subject the possible improvement of the human breed under the existing conditions of law and sentiment.

Dr. Galton in part said: "The possibility of improving the race of a nation depends on the power of increasing the productivity of the best stock. This is far more important than that of repressing the productivity of the worst. They both raise the average, the latter by reducing the undesirables, the former by increasing those who will become the lights of the nation. It is, therefore, all important to prove that favor to selected individuals who might so increase their productivity as to warrant the expenditure in money and care that would be necessitated. An enthusiasm to improve the race would probably express itself by granting diplomas to a select class of young men and women, by encouraging their intermarriages, by hastening the time of marriage of women of that high class, and by provision for rearing children healthily. The means that might be employed to compass these ends are dowries, especially for those to whom moderate sums are important, assured help in emergencies during the early years of married life, healthy homes, the pressure of public opinion, honors, and, above all, the introduction of motives of religious or quasi-religious character.

Dr. Galton dwells with insistence upon religious enthusiasm as a spur to improve the race, and rightly says, so noble is its aim that it might well give rise to the sense of a religious obligation.

Nevertheless, it is to be feared that the religion or cult of physical improvement will not quite prove a stimulus sufficiently strong to induce persons to marry those best suited to them.

The fact is undoubted that many most fitting marriages are hindered from prudential reasons; but this is only one of the numerous disadvantages which civilization imposes on the race.

Dr. Galton is of the opinion that it would be possible to alter the conditions of life, so that the most prudent course would be for such persons to marry at an early age.

If this change in the existing order of affairs could be brought about, it would be a long step in the right direction; but it is a question whether stirpiculture applied to the human race could be successfully carried out as things are at present.

Physical and mental improvement is greatly needed, and the race would benefit greatly if practical methods tending to this end were devised.

Almost all the suggestions advanced have been visionary and impracticable.

The inculcation by example, precept, and especially by education of the gospel of health and cleanliness, the repression as far as is possible of criminality, vice, and drunkenness, are the means at hand whereby the evils of modern life can undoubtedly be considerably lessened.

Perhaps in measures of this nature lies the mental, physical, and moral redemption of the race rather than in well-meant but utopian schemes, which offend the intelligence of the people at large and are repugnant to their ideas of freedom.

CANCER PARASITES AND CELLULAR INCLUSIONS.

ONE of the salient questions in the controversy on the etiology of cancer is the confusion of degenerated cellular elements and cellular inclusions with parasites, and *vice versa*. A recent article from the pen of Sanfelice (*Riforma Medica*, October 12, 1901), who, with Leopold and Plimmer, was instrumental in placing certain blastomycetes on the list of possible parasitic causes of cancer, deals at length with the interpretation of such atypical cellular forms. In defense of the blastomycete which he has described as the cause of cancer, the learned Italian is led to say that all the recent investigators who have denied the validity of the claims of the Plimmer-Sanfelice parasite have mistaken cellular inclusions for blastomycetes, and that therefore the experiments which they have recorded to disprove the specific nature of the blastomycete aforesaid cannot be considered seriously.

Nichols of Boston ("First Annual Report of the Cancer Committee," Boston, 1900) found the Plimmer-Sanfelice blastomycete in thirteen cases of cancer of the breast out of a total number of sixteen cases. He did not find these organisms in sarcomata, and he was unable to prepare cultures of the parasites, but on injection of blastomycetes, furnished by Plimmer and Sanfelice themselves, into animals, he found that the parasites which appear in the tissues of the inoculated animals differed in appearance from those described by the discoverers of the parasite. He therefore denied that blastomycetes could cause cancer, and attributed the positive results obtained by Sanfelice to mere coincidence. To this Sanfelice replies that both Plimmer (*Practitioner*, April, 1899) and Leopold (*Archiv für Gynäkologie*, Vol. 61, 1900) obtained positive results in inoculation, and found that epithelial tumors were produced in the animals inoculated with blastomycetes. Sanfelice concludes that Nichols must have mistaken cellular degenerations in the tumors examined for parasites—an error which is clearly shown, he says, by the illustrations furnished by Nichols.

Borrel (*Annales de l'Institut Pasteur*, 1901) concluded that all the parasites described as causes of cancer by Nils Sjöbring, Soudakewitch, Foa, Ruffer, Walker, Plimmer, Podwyssotzky, and Sawtchenko are structures derived from the atypical development of one of the elements of cancerous cells—the sarcoplasm. Borrel's ingenious theory, however, is, according to Sanfelice, without any foundation, for, as a matter of fact, all the intracellular structures which Borrel designates in his illustrations as parasitic have nothing in common with the intracellular parasite of cancer. Borrel did not take into consideration the fact that most authors on the subject, in their search for coccidia-like forms, have figured in many places atypical sarcoplasm or cellular inclusions that had nothing parasitic about them, together with true parasites, and in his article considers the pseudo-parasites only.

The recent work of Harvey R. Gaylord of Buffalo (*American Journal of the Medical Sciences*, May, 1900) is next reviewed by Sanfelice. Gaylord, as is well known, inoculated some liquid obtained from the peritoneal cavity of a patient with adenocarcinoma into a dog and two guinea-pigs. One of these animals showed lesions in the form of epithelial new growths in the lungs. Gaylord examined a number of tumors, and found that they always showed the presence of the parasites described by Plimmer, but asserted that these parasites were not blastomycetes but protozoa. From Gaylord's article, as well as from his photographs, Sanfelice concludes that the distinguished American pathologist did not see Plimmer's parasites in the tumors examined, but mistook for parasites certain cellular degenerations. The identity of Plimmer-Sanfelice parasites with blastomycetes is now an established fact, and according to Sanfelice, Gaylord's hypothesis that these structures are protozoa is merely based upon their resemblance to the parasites of vaccine injected into the cornea of rabbits. The latter organisms were, however, only provisionally placed in the class of protozoa by Garnieri, and their exact zoologic status has not as yet been determined.

According to Sanfelice, certain cellular degenerations are very easily mistaken for cancer parasites, and special methods of fixation and staining are required to differentiate these cellular deformities from blastomycetes.

The careful and authoritative work of Sanfelice should command the attention of all who are interested in the cancer question, and yet it is difficult to believe at first thought that such authorities as Nichols, Borrel, and Gaylord actually mistook cellular inclusions for parasites, and published results based upon the assumption that they were dealing with the Plimmer-Sanfelice blastomycete. The charge is a grave one, and demands refutation.

MILK AND THE TUBERCLE BACILLUS

The milk question in all cities is a most important one, and it has been brought somewhat unpleasantly to the notice of the inhabitants of New York by the recent report of the milk commission. The facts which have come to light by means of the investigations of the commission have naturally aroused feelings of distrust as to the healthfulness of milk as a diet for young children.

The situation in this respect has not been improved by the declarations made by some physicians that pasteurized milk has a tendency to produce scurvy.

The assertion is now made that not only is pasteurization an uncertain safeguard against infection, but that sterilizing milk by boiling is frequently an ineffective process.

The Bristol *Medical and Chirurgical Journal* says: "It is now commonly understood that milk can be deprived of danger from all kinds of germs by raising it to the temperature known to be fatal to these germs. Less than the boiling temperature suffices for this purpose, and hence the custom is growing of submitting the milk to pasteurization. This, however, has proved itself to be beset with fallacies, inasmuch as many cases of scarlet fever have recently been traced to milk which was called pasteurized."

The London *Hospital*, January 18, calls attention to the temperature necessary to render the harmful germs in milk inocuous, and says: "The exact temperature to which milk must be raised in order to destroy tubercle bacilli which may be present has always been a disputed point. Bang stated that 85° C. was sufficient; Foster, 70° C. for 10 minutes; de Man, 80° C. for four minutes; while Gaultier maintained that the tubercle bacillus could in this medium resist a temperature of 85° C. for six minutes. The milk from cows with advanced tuberculosis of the udder is more alkaline than that of healthy cows, or those only lightly infected. Tubercle bacilli, like other microorganisms, have greater powers of resistance when growing in an alkaline medium, and consequently in a heavily infected alkaline sample a temperature of 80° C. maintained for ten minutes may be insufficient to kill the tubercles present.

In a commercial pasteurizer, Farrington and Russell found milk heavily laden with tubercle bacilli, and kept for five minutes at a temperature of 140° F., was still infective, but inocuous, if the time was prolonged to ten minutes. For safety a full twenty minutes should be allowed, the vessel being closed to prevent the formation of a skin upon the surface of the milk."

The dicta of the above observers serve to emphasize the need of procuring milk in the first instance as free from contamination as possible.

Boiling and pasteurizing milk certainly do not add to its nutritive qualities, necessary as these processes may at times be, and the chief efforts of the philanthropists and sanitarians might be directed with advantage to insuring a supply of pure milk.

It might seem that, if the recommendations of the milk commission be faithfully carried out, such a result would eventuate.

A CAUSE FOR AMERICAN CATARRH.

It is a well-known fact that modern changes of temperature induce catarrhal affections, and it is also evident that the best prevention of a "cold" is a ready adaptation to the varying conditions of an uncertain climate. The latter implies a certain resisting quality of the respiratory mucous membranes which must be necessarily developed along rational lines. The hardening processes thus become questions of vitality, habit, and environment.

The old Indian explained his immunity against low temperature by explaining that he was "all face." It was with him the habit of exposure to inclemencies and its reactive protecting tendency. The other extreme is seen in the coddling process which our modern methods of civilization encourage. "When houses were made of willow, the men were made of oak." Our superheated houses reverse these old-time conditions.

The dry-hot air of the modern dwelling is undoubtedly the most prolific of all the predisposing causes of catarrhal troubles. The mucous membranes are thus placed in the worst possible condition for resisting the impression of the outside atmosphere. Their natural protective secretions are not only decreased, but the blood supply of the air passages becomes relatively superabundant, congested, and sluggish, and the beginning of the end is evident enough.

Persons who are luckily unaccustomed to these high temperatures often experience a sense of oppression from the same cause. It is the protest of healthy resistance against artificial enfeeblement. Foreigners say with truth that Americans literally bake themselves in their houses, and there is in this connection also much reason for their opinion as to the cause of the American catarrh.

TIME REQUIRED TO TREAT SUCCESSFULLY CONSUMPTIVE CASES IN SANATORIUMS.

In the sanatorium treatment of consumption, many points must be taken into consideration.

Usually, when a State or municipality erects buildings in which to treat and care for needy persons suffering from disease, an undue portion of the sum appropriated to the purpose is devoted to the construction of magnificent edifices.

For example, the State Hospitals of New York are palatial in conception and ornate to a degree. This is very well in its way, but it suggests the question as to whether it would not be wiser to expend less money on the buildings themselves, and more on the patients.

With regard to sanatoriums for pulmonary tuberculosis, isolated buildings of small size and of modest construction will meet the exigencies of the situation far better than splendid specimens of the architect's ability and of the builder's capacity.

Another point which is deserving of consideration is the duration of stay in a sanatorium necessary to effect decided improvement in health.

The *Lancet*, December 7, ult., discusses this matter and says: "Naturally, the earlier the stage of the disease at the time of admission, the shorter will be the period of residence necessary. Among the working classes, unfortunately, the seeming necessity for pursuing employment as long as possible militates against their receiving institutional treatment before the disease has made considerable inroads. Another fact which calls for as extended a period of treatment as the circumstances of the sanatoriums permit, is that a number of the patients will return to home surroundings which are not ideal in their condition.

"The shortest period of treatment—that is, in a case in which the physical signs give evidence that the disease is in an early stage—will by most sanatorium physicians be fixed at three months."

The difficulty is to be able to tell when persons are so slightly affected as to benefit by a three months' treatment. A working man who is suffering from consumption in the earliest stage is not likely to pay much attention to his condition—even if he is aware of it—but is apt to imagine that he will soon be better and continue to work.

Thus there is no doubt that the large majority of workers with pulmonary tuberculosis will not seek treatment until they are in the intermediate stage, and are more or less compelled to stop work.

Therefore it may be said that a six months' treatment at a sanatorium will be in most cases essential really to benefit the sufferer.

The early recognition of tuberculosis is the main point to be aimed at, but the difficulties in the way of such a diagnosis are many.

If a feasible plan can be devised to overcome these obstacles, the sanatorium treatment of the working and indigent classes will undoubtedly bring about unspeakable benefits to the whole community.

BELLEVUE REFORMS.

The fulminations of the medical and lay press against the conduct of Bellevue and its allied hospitals, at any rate to some extent, has had the desired effect. A few months ago the revised charter provided that the city hospitals should pass from the control of the Charities Department to a board of trustees consisting of seven members.

The new board has been appointed by Mayor Low, and on Saturday entered upon its duties. The trustees take under their management Bellevue, Harlem, Gouverneur and Fordham hospitals, but the Morgue remains under the supervision of the Charities Department.

When a patient dies in any one of the above hospitals, the body is removed to the Morgue, and consequently is in the charge of the Charities Department.

Many changes will be introduced in the methods of management now prevailing in the city institutions, and the insane pavilion of Bellevue, it is said, will receive marked attention at the hands of the recently appointed officials.

Dr. Flavius Packer, the first assistant resident physician of the Matteawan State Hospital for Criminal Insane, will take charge of the Bellevue Insane Pavilion. Dr. Packer will have as assistant Dr. Gregory, of the Long Island State Hospital. Under Dr. Packer's management, Dr. Brennan said, the insane pavilion at Bellevue would practically be a temporary insane asylum.

The announcement was likewise made that the board of trustees had designated committees of two, who would visit the hospitals once a week at least, and that a plan had been arranged whereby one of the members of the board would always be in attendance at Bellevue.

It is also reported that the trustees have decided to retain Dr. George T. Stewart as superintendent of Bellevue, as well as his assistant, Michael J. Rickard.

The trustees intend to provide better paid help for Bellevue and thoroughly to reform the alcoholic ward.

The saying that "new brooms sweep clean" has a rare opportunity of being put into practice to the good of every one concerned in the city hospitals of New York.

When Bellevue is rebuilt and its system of working established upon humane, intelligent and scientific lines, the chief municipal hospital of New York will be a credit rather than, as heretofore, a somewhat doubtful blessing to the largest and richest city of this continent.

Cats and Disease

That animals and birds may spread disease among human beings has long been conjectured, although no absolutely positive proof in support of the view has as yet been forthcoming.

The nearest approach to conclusive evidence on this point has been the intimate connection between the occurrence of bubonic plague among men and rats. It is thought that the fact of plague-infected rats being always present in those localities in which the malady has attacked the human race must be something more than a coincidence. How else to explain the widespread dissemination of plague in countries far distant from the seat of the original outbreak!

In the case of tuberculosis, again diseased cattle are a probable cause of spreading infection. Parrots have been suspected of communicating to the human species a certain disease, while the insect world is known to be responsible for conveying to man various maladies.

Some time ago, the theory was mooted that the domestic cat might be an infective agent; but little notice was taken of this aspersion on the fair fame of the universal home pet. However, the matter has again cropped up, and in the *Sun*, February 2, it is stated that an epidemic of diphtheria which prevailed recently in Knowlton, Canada, has been traced to cats.

Suspicion of the cats as a means of spreading the disease having been aroused, the matter was looked into, and it was found that nearly all these animals were suffering from sore throats. Short shrift was then made of the cats, the whole colony in that particular district being made away with, root and branch.

With the extermination of the cats, it is declared that the epidemic of diphtheria quickly subsided.

The account proceeds to state that the spread of the disease was found to be much more far-reaching than at first supposed and that foxes which have a special predilection for the flesh of cats, were discovered dead in large numbers in the vicinity of Knowlton, doubtless having regaled themselves on the sick cats, which, after the manner of their kind, had crawled to the woods to die in solitude.

Perhaps the foregoing version of the epidemic at Knowlton may owe some of its sensational features to the imaginative powers of the journalist, but at the same time it is pervaded by a singular plausibility.

There would seem to be no inherent reason why an infectious malady, such as diphtheria, if contracted by cats, should not be by them communicated to human beings.

Nevertheless, it might be well first to find out whether cats are subject to diphtheria, and if so, whether the disease is identical with human diphtheria.

As to Gynecological Operations Before Medical Classes

The action of the warden of Cook County Hospital in Chicago in refusing to permit operation on a woman in the clinical amphitheater on the ground of protecting her and similar patients from indecent exposure before medical classes is quite worthy of a lay-political official unable to attribute to others higher conceptions of modesty than his own. It seems that his [illegible], many legitimate opportunities for clinical instruction would be removed, and thereby the means for alleviating disease and preventing death restricted. Medical men are, as a rule, not less considerate than others of the rights and privileges of their fellows.

Another French Scientist Honored

A few weeks ago Berthelot received distinguished recognition at the hands of his countrymen of his life-long service to science. Now another somewhat less eminent worker in the same field has been honored by his associates and admirers.

In the Medical Amphitheatre of the College de France on Sunday morning, January 29, there assembled leading Frenchmen representing every branch of literature, medicine, art, and politics, to do homage to Etienne Jules Marey, professor of the natural history of organized bodies and director of the physiological experiment station at the Parc des Princes.

The special reason for this celebration was the completion of Professor Marey's fifty years of university work.

Although Marey's original researches in animal physiology do not compare with those of his illustrious contemporaries Pasteur and Berthelot, nevertheless they have given an impetus to many arts and sciences, and have helped the progress of modern medicine.

The first discoveries linked with his name were the method of observing and recording the movement and rhythm of vital actions—walk, gallop, flight, blood pulsations—as well as the photography of animal movements.

The Paris correspondent of the *Evening Post*, February 1, says that Professor Marey was brought up in an atmosphere of science, as he began as substitute of Flourens, who himself held the same relation to Cuvier.

M. Gaston Paris, director of the College de France, in an eloquent speech summed up Marey's achievements in the following well-chosen words: "Your idea of unifying the registration measures of physiological phenomena will render, I do not fear to say, when it is realized, a service of first order, not only to science, but to humanity, for it will aid us effectively to know ourselves better in the working of our physical and psychic life, and so make us abler to direct our destinies and consciously to favor our evolution for the best."

In this country the magnificient contributions of Frenchmen to science, and especially to medical science in the half-century just passed, have hardly been estimated at their full value.

The discoveries and work of the Germans—which have been much more widely heralded—have obscured to some extent the equally valuable benefits to mankind resulting from French scientific research.

It is probable that in the time to come, when men are able to dispassionately review the outstanding events of the medical and scientific world, of the latter half of the twentieth century, a verdict will be given that Pasteur accomplished more for the good of his kind than any other scientist within the same period.

We therefore take the opportunity of tendering to Marey, his worthy follower, our appreciative congratulations.

Tuberculosis in London.—Consumption is worst in the Strand District of London, where the deaths from this disease are 336 in every 100,000 yearly. The rate for Great Britain is 140 per 100,000.

News of the Week.

Smallpox in spreading in many places throughout the country, and in New York City the disease shows no signs of having been got under control by the health authorities. There were more than twice as many deaths from this cause in January as there were in December, and three times as many as there were in November. The Health Commissioner has urged all hotel keepers to see to it that their employees are vaccinated at once, offering to relieve them of all unnecessary trouble and expense if they will issue the order for the employees to submit to vaccination. If they do not consent to this being done, the commissioner warns them that the hotel will be quarantined if any of the people connected with it get smallpox. The post-office clerks and carriers have been vaccinated, and so have most of the children in the schools both public and parochial.

A Swindler of Physicians.—A man has been arrested in Chicago on the charge of having swindled several hundred physicians in Illinois, Iowa, Michigan, Minnesota and Wisconsin out of small sums of money. He is charged with having fraudulently obtained cash subscriptions to a Chicago medical publication, offering the subscription at a reduced price, and then keeping all that was collected.

Typhoid Fever Prevalent in Philadelphia.—The people of Philadelphia are again paying tribute in life for their failure to provide themselves with pure water. Large sums of money are being expended upon a system of filtration, but the progress is slow, and the end appears yet far off. For the week ended February 1, there were reported to the Bureau of Health 201 cases of typhoid fever and 21 deaths, as against 117 cases and 9 deaths for the preceding week. The disease prevails widely throughout the city, and the increased prevalence is attributed to impurity and inadequacy of the water supply. Some sections of the city being said to receive their supply by direct pumpage, the storage capacity of the reservoirs being insufficient for the needs of the people of these sections. There has been a marked increase in the number of cases of typhoid fever since the first of the year, as is shown by the following figures:

	CASES.	DEATHS.
For the week ending January 4....	70	6
" " " 11.....	41	8
" " " 18.....	81	5
" " " 25.....	117	9
" " February 1......	201	21

The number of cases of smallpox (73) and the number of deaths from this disease (13) for the week were smaller than for the preceding week, namely 90 and 19.

There were 83 cases of diphtheria and 16 deaths as compared with 65 cases and 10 deaths, and 65 cases of scarlet fever and 9 deaths, as compared with 72 cases and 3 deaths for the preceding week.

A Pan-American Sanitary Code.—The Pan-American Conference, which has just closed its sessions in Mexico City, on January 28, passed the International Sanitary Convention, though the report had to be remodelled owing to the withdrawal from the committee of the Argentine delegate, who objected to the idea of an international sanitary bureau with headquarters in Washington. The Argentine delegates have persistently voted against any project looking to the creation of a bureau at Washington having authority in international matters.

A Tuberculosis Hospital on Blackwell's Island.—The Commissioner of Charities of this city has ordered the removal of all phthisical patients from Bellevue Hospital to one of the buildings formerly occupied by the Manhattan State Hospital on Blackwell's Island. Consumptive patients in the general wards of the City Hospital will also be removed to this pavilion within a few days. This is a provisional arrangement to relieve the general hospital from the presence of the consumptive patients and to provide for the latter special care and treatment. The building they will occupy will accommodate about 120 patients. There are two other available buildings with a total accommodation of about 350, but these will require some alterations before they can be ready for occupancy.

The Mortality in New York State in 1901.—The total number of deaths in this State last year was 130,757, making the death rate 18 per thousand population. The mortality was 7,500 in excess of the average of the past five years, but the rate was the same as that of 1900. The infant mortality was unusually low, being 3,500 less than in 1900, and 2,500 less than the average of the past five years. The deaths at seventy years and over were only one-third as many as those under five years in the maritime district; in the rest of the State they exceeded them by 4,300, and constituted 27 per cent. of the total.

The Carnegie Institution.—The Board of Trustees of the Carnegie Institution met in Washington on January 28, received Mr. Carnegie's deed of gift, and elected officers. Dr. Daniel C. Gilman of Baltimore was chosen *President;* Abram S. Hewitt of New York, *Chairman of the Board of Trustees;* Dr. John S. Billings of New York, *Vice-Chairman,* and Dr. Charles D. Walcott, *Secretary.* The deed of gift provides that the income of the $10,000,000 is to be expended in "founding in Washington an institution to co-operate with those now or hereafter established, and, in the broadest and most liberal manner, encourage investigation, research, and discovery, show the application of knowledge to the improvement of mankind, provide such buildings, laboratories, books, and apparatus as may be needed, and afford instruction of an advanced character to students properly qualified to profit thereby." One of the main objects of the institution is to discover "the exceptional man in every department of study, whenever and wherever found, inside or outside of schools," and enable him to make his favorite line of work his life work. Still other objects are to increase the facilities for higher education, to throw open to students the advantages afforded by the Government institutions at Washington, and to insure the prompt publication and distribution of the results of scientific investigations.

Surra Among the Army Mules in the Philippines.—A despatch from Manila states that the fatal and much-dreaded surra of Indian Burmah has invaded the Philippines and is destroying horses and mules with amazing rapidity. The disease was at first mistaken for glanders, but failed to yield to treatment, and puzzled for months the best veterinarians. A bacteriological investigation has now revealed the presence of the specific parasite of surra. The disease affects horses, mules, camels, dogs, and monkeys, and is almost always fatal. In Manila alone the Quartermaster's Department lost 300 horses within four months.

The New Control of Bellevue and Allied Hospitals.—On Saturday, February 1, Commissioner of Charities Folks formally turned over the management of Bellevue and subsidiary city hospitals to the Board of Seven Trustees appointed by Mayor Low on January 20. This was in accordance with the provisions of the revised Charter. The board, as selected by Mr. Low, is as follows: Dr. John W. Brannan, *President;* James K. Paulding, *Secretary,* and Messrs. Myles Tierney, Samuel Sachs, Marcus Stine, Theodore E. Tack, and Howard Townsend. Commissioner Folks will be an advisory member of the board. The first official act of the board was the appointment of Dr.

Thomas Parker to have charge of the insane pavilion at Bellevue. Dr Parker has for some time been first assistant resident physician at the Manhattan Asylum for the Criminal Insane. The selection was made on the recommendation of Dr Peterson, President of the State Lunacy Commission. Dr Parker has appointed Dr Gregory of the Kings County Asylum as his assistant. Dr Thomas L [illegible], who heretofore has been connected with the insane pavilion, has been transferred to the Board of Health. The new board has established the rule that each hospital will be visited once a week by one of the seven trustees, and that a meeting of the full board will be held every Thursday at Bellevue.

A Physician's House Burned.—The house of a physician in Appleton, Wis., was destroyed last week by fire, which was suspected to have been of incendiary origin, there having of late been numerous threats against the man. He is said to be a disbeliever in the contagiousness of smallpox, and, in order to prove the correctness of his theory, smeared himself with the secretions from smallpox lesions, and then started on a visit to several towns about his home. Smallpox prevails extensively now in that region, and many of the friends of the sufferers have attributed the epidemic to this doctor's freak experiment.

Medical Society of the District of Columbia.—At a recent meeting of this society the following officers were elected for the present year: *President*, Dr Samuel S. Adams; *Vice-Presidents*, Drs. J. W. Chappell and A. R. Shands; *Treasurer*, Dr C. W. Franzoni; *Corresponding Secretary*, Dr. Thomas C. Smith; *Recording Secretary*, Dr. Francis P. Morgan; *Librarian*, Dr. Edwin L. Morgan.

The Health of Chicago.—According to the *Weekly Bulletin of the Chicago Health Department*, physicians in that city are unusually busy and the death rate still declines. It is not meant, however, to flatter the profession unduly by implying that the latter is the result solely of the former. There is a vast amount of sickness in the city, but the prevalent maladies—except scarlet fever—are of a mild type. The 480 deaths from all causes recorded during the week ending January 25, give an annual rate of only 13.73 per thousand of population—a reduction of about 7 per cent. from the rate of the previous week, and of 3.8 per cent. from that of the corresponding week last year. There has been a notable increase in the demands upon the department's laboratories for bacterial examinations since the appeal was made for a more general resort to these means of determining the character of obscure symptoms, especially that of influenza. Fully 60 per cent. of all examinations reveal the presence of the bacillus of this disease, either pure or associated with other germs—chiefly those of pneumonia. But the number of examinations called for is still wholly disproportionate to the prevalence of the disease.

Senate Passes Lunacy Bill.—The State Senate on Wednesday last, passed the bill abolishing local boards of management for insane hospitals. The Governor will accord a public hearing before taking final action.

A Gift to the Harvard Medical School.—President Eliot of Harvard University recently announced to the medical faculty that Mr. John D. Rockefeller proposed to give $1,000,000 in aid of the medical school, provided other friends of the university would raise a sum of money in the neighborhood of $500,000, to be used by the medical school for land, buildings, or endowments. It was stated that this condition would doubtless be speedily complied with. Since the announcement last June that Mr J. Pierpont Morgan would erect three of the buildings, the plans of the architects have called for two additional laboratory buildings, and a considerable fund is also needed to provide for the increased running expenses of the school.

Association of French-Speaking Physicians of North America.—A committee of French Canadian physicians has been formed for the purpose of organizing a new medical society for the men of French speech in Canada and the United States. It is proposed to hold the first meeting of the society in Quebec in the present year, at which time will also be celebrated the semi-centennial of the establishment of Laval University, the alma mater of most of the present generation of French Canadian medical men.

Seizure of Stone Baking Powder.—The Health Department of this city recently seized as dangerous to health nearly two tons of baking powder, half a ton of which was on sale at a department store. The stuff was being advertised for sale at four cents a pound. The Health Department got some and analyzed it, and found that it contained between 25 and 30 per cent. of a stone mined in Tennessee, which was ground up very fine. The stone, it was said, was mostly silicate of magnesia.

A Physician's Unfortunate Experience.—Dr H. A. Hare of Philadelphia, while riding a few days ago in an automobile he was testing, was, by mistake, apprehended for another chauffeur, on account of fast riding. Despite his protestations, Dr. Hare was taken in a patrol wagon to the police station, where he was confined for an hour without being permitted to communicate with his counsel or his family, until released by the intervention of friends who had learned of his misadventure.

Philadelphia Neurological Society.—At a stated meeting, held January 28, Dr. Wm. G. Spiller exhibited "A Case of Paralysis of the Face and the Upper and Lower Extremities on the Right Side, and of the Tongue and Muscles of Mastication on the Left Side." The patient was a colored woman with a history of miscarriages, but none of syphilis, in whom the hemiplegia developed after an apoplectic seizure that had been preceded by drowsiness. It was thought that the alternate character of the symptoms was indicative of multiple lesions. Dr. Spiller exhibited also "A Case of Right Hemiplegia, with Paresis of the Muscles of Mastication upon the Affected Side." In addition to increased knee-jerk and Babinski sign on the paralyzed side, there was a marked contraction of the tendon of the anterior tibial muscle, when, with leg flexed, an attempt was made to flex the thigh on the trunk, also dorsal extension of the great toe, when, in the recumbent posture an attempt was made to elevate the extended lower extremity; and also flexion at the knee-joint, when an attempt was made to arise from the recumbent to the sitting posture without aid.

Dr. Max H. Bochroch exhibited "A Case of Superior Tabes," occurring in a cigarmaker who was compelled to relinquish his work on account of numbness and delayed sensation in the fingers, and which were present also in the lower extremities. In addition there were lancinating pains, girdle sense, and distinct incoördination in the upper extremities, although the station was good. The knee-jerk could not be elicited at all on one side, while on the other it was capricious and often elicitable only on reinforcement. The pupils were small, and failed to respond either to light or in accommodation. Speech and mental activity were slow, the tongue was tremulous, and the possibility of paretic dementia was suggested. Syphilitic infection was denied.

Dr. Chas. S. Potts exhibited "A Case of Progressive Muscular Atrophy (Aran-Duchenne Type), in which the Atrophy Began in the Extensors of the Hands and the Fingers." The patient had been a painter, then a sailor, and, finally, a locomotive engineer. He was compelled to relinquish his occupation on account of the impaired motility in the hands.

Drs. A. P. Francine and D. J. McCarthy exhibited "A Case of Facial Tic, in which Each Contraction is Followed by Complete Paralysis in the Facial and Hypoglossal Distribution on the Same Side." The patient was a colored woman, in whom, following a slight injury of the scalp, a convulsion occurred, whose exact nature, whether hysterical or epileptic, could not be determined. It was thought that the symptoms might be due to a small lesion involving the cerebral cortex.

Dr. F. Savary Pearce exhibited "A Case of Poliomyelitis with Increased Knee-Jerk" in a child presenting no evidence of cerebral disease.

Dr. A. D. Buckley, by invitation, presented a communication entitled "Carcinoma of the Spine with Autopsy."

The following officers were elected for the ensuing year: *President*, Dr. J. K. Mitchell; *Vice-Presidents*, Drs. F. X. Dercum and Jos. Sailer; *Secretary*, Dr. A. A. Eshner; *Treasurer*, Dr. Guy Hinsdale; *Councillors*, Drs. D. J. McCarthy, W. G. Spiller, and W. C. Pickett.

Dr. Thomas H. Manley of this city was recently the defendant in an action for malpractice brought against him by a woman who alleged the unnecessary removal of a joint of the thumb. The case was tried in Part IX. of the New York Supreme Court, and the jury, after only five minutes of deliberation, brought in a unanimous verdict in favor of Dr. Manley. An unpleasant feature of the affair was the fact, brought out at the trial, that the suit was begun on the advice of another physician.

The Establishment of a Missouri State Sanatorium for Consumptives was recently urged by resolution of the Medical Society of the City Hospital Alumni of St. Louis. The preamble states that, while several State governments have recognized the necessity for the better protection of the public against tuberculosis by the establishment of sanatoria, Missouri has as yet done nothing in this direction. The society has therefore taken the initiative in arousing public opinion in favor of the establishment of a State institution of that kind, and has appointed a special committee to agitate the question at society meetings, and in the local and medical press. The special committee consists of Drs. George Homan, *Chairman*; Ludwig Bremer, Louis H. Behrens, Francis Reder, and R. B. H. Gradwohl, *Secretary*.

Obituary Notes—Dr. Charles H. Burnett of Philadelphia died at his home in Bryn Mawr on January 30, at the age of sixty-one years. He was a graduate of the Medical Department of the University of Pennsylvania in the class of 1866. After graduation, he passed a season of study in Europe, devoting special attention to diseases of the eye and ear. His practice was in aural diseases, in which specialty he was justly regarded as a high authority. He edited a cyclopædic treatise on diseases of the ear, nose, and throat, and was the author of a recently published special treatise on diseases of the ear. He was a member of the American Otological Association, of the Philadelphia College of Physicians, and of other special and general societies.

Dr. Wm. A. Dudley of Petersburg, Va., died of pneumonia on February 1, at the age of seventy-six years. He was a graduate of the Medical Department of the University of Pennsylvania in the class of 1850, and had practised medicine in Petersburg for almost half a century.

Dr. Bowman H. Shivers of Haddonfield, N. J., died at his home in that place on February 1, at the age of sixty-seven years. He was a graduate of the Medical Department of the University of Pennsylvania in the class of 1858, and later from the Hahnemann Medical College of Philadelphia.

Dr. Henry Rutgers Baldwin, President of the Board of Health of New Brunswick, N. J., died at his home there on February 3, of pneumonia. He was born in New York City on September 18, 1829, and was graduated from Rutgers College in 1845. He then entered upon the study of medicine with Dr. George J. Janeway of New Brunswick, receiving his medical degree from the College of Physicians and Surgeons, New York, in 1853. He began practice in New Brunswick in December, 1855. At the time of his death he was a member of the Board of Managers for the New Jersey Hospital for the Insane, the New Jersey Medical Society, the Middlesex County Medical Society, the New Jersey Microscopical Society, and the medical staff of the Wells Memorial Hospital at New Brunswick. He was in every respect the type of the old-fashioned family practitioner and kept abreast of his work to the last.

Obituary.

JOHN T. METCALFE, M.D.,

THOMASVILLE, GA.

Dr. Metcalfe, who died of old age on January 30, at his home in Thomasville, Ga., was for many years one of New York's most noted physicians. The son of a physician, he was born in Natchez, Miss., on July 10, 1818, and was educated at West Point, where he was graduated in 1838. He was, for a time, Lieutenant in the Artillery Service, but was soon transferred to the Ordnance Department. He resigned from the army in 1840, and began the study of medicine at the Jefferson Medical College, Philadelphia, from which he was graduated in 1844. After graduation he studied in the schools of Dublin, Edinburgh, Vienna, and Paris, and then returned to practise his profession in this city. He was the first of a line of Southerners who have contributed so largely to the medical forum of New York. For many years he was in partnership with Dr. T. G. Thomas; afterward with Dr. William M. Polk, and still later with Dr. J. S. Ward. He was prominent as a teacher and expounder of medicine in college and medical society. He lectured for many years at the College of Physicians and Surgeons, and to the end held the post of emeritus professor of clinical medicine there. He was consulting physician to Roosevelt, Bellevue, St. Luke's and the Woman's hospitals, the Orthopedic Dispensary, and the Hospital for the Relief of the Ruptured and Crippled. He was an active member of many medical societies, among which may be mentioned the New York Medical and Surgical Society, the County Medical Society, the New York Society for the Relief of Widows and Orphans of Medical Men, the New York Pathological Society, the Academy of Medicine, and the Medical Journal Association of the City of New York. He was one of the earliest members of the academy and gave to it his large and valuable library upon his retirement from practice about fifteen years ago. The portrait of him at the academy was presented by Dr. Thomas, his former associate. Since Dr. Metcalfe's retirement a new generation of physicians has grown up to whom he was hardly known, even by name; but to the older men the memory of his charming presence, his witty and brilliant conversational gifts, and his deep learning can never fade.

Correspondence.

OUR LONDON LETTER

([illegible])

[illegible]

London, January [illegible]

Yesterday the King opened his second Parliament with all the pomp and ceremony of such occasions. Among the measures announced in His Majesty's speech to be brought forward, those of more medical interest are to deal with the London water supply, the sale of intoxicants, and the lunacy laws.

There have been rather fewer cases of smallpox during the last three days, but if we take the numbers for the week, there is no diminution.

The report of the Asylums Board, which I stated was about to appear, deals with the completed cases only, i.e., those ending in death or discharge. Of course, at present the percentages are provisional, but they give just such evidence as might have been expected. The total mortality rate was 14.21 per cent. of vaccinated, [illegible] of doubtful, and [illegible] of unvaccinated cases. Among patients admitted during the year, twenty-one were employed mostly by local authorities, in disinfecting work, and one of them died; not one of them had been revaccinated since infancy. Sanitary inspectors and others specially exposed had also been admitted. At the smallpox hospitals and in the ambulance service of the board revaccination is a condition of employment. Of 2,198 persons so employed from 1884 to 1900, in which 17,000 cases were admitted, only seventeen contracted the disease, of whom thirteen were not revaccinated until after they had joined the service, and four were workmen who escaped observation. Not one case has occurred during the past year in the new staff of the hospital ships; not one has contracted smallpox in the last eight years, and not one of the staff of these hospitals has ever died from the disease.

The numerical inadequacy of orderlies or male nurses (medical staff corps) in the army has been painfully demonstrated during the war, leading to the engagement of a number of St John Ambulance men. Profiting by the experience of the war office in regard to the R.A.M.C., the admiralty have been considering the state of their own nursing staff—"the sick-bay men." Inspector-General of Hospitals, Dr H. C. Woods, has been inquiring into the matter for some time, and the result is that a scheme will probably be shortly promulgated for organizing a reserve of nurses which could be called upon to supplement the sick-bay men during a naval war. Dr. Woods has been prominently associated with the St. John Ambulance Association, but I hope he will not rely altogether on the men to be obtained from it. If the pay and conditions of service are reasonable, he would be able to obtain men completely trained as nurses, such, for instance, as those who have gone through the training under the R.A.M.C.

The average newspaper reporter seems to take special delight in girding at the profession. It does not seem to occur to him that absolute ignorance of matters medical is any disqualification for attempting to elucidate them. The editors of the cheaper papers seem happy to pass any gibe at the doctors, and often display extreme hostility to medical science. Their attitude has been well illustrated in the case of the difficulty at the Macclesfield Infirmary, caused by the appointment of a female house-surgeon concerning which I lately wrote to you. Scores of newspapers opened a campaign against the profession, pretending that the whole difficulty was due to the opposition of the staff to women doctors, supported by a selfish trade-union policy. No protest, no denial, availed. The cry of woman's rights was raised, and at first the lady doctor herself encouraged this, though she must have known better. She must have perceived that the Infirmary had not proper accommodations for both a male and a female house-surgeon, and should have known, too, that there are numerous surgical cases that are more properly intrusted to their own sex. She seems to have realized this, and resigned when the leading lady doctors declined to support her. It is said she will now open practice in the town, to which no one will object, and the *Express* raises a pæan on her triumph, and declares she must have a partner to help her in the work which is waiting for her. Very well, that only affects those concerned. The governors have now conceded to the honorary staff a voice in the selection of the residents, such as is provided in all well-managed hospitals, though one governor withdraws his support in consequence, which looks like preferring his prejudices to his philanthropy.

Another illustration of the ignorance of the press on professional questions is [illegible] by the [illegible] a very reasonable decision which lately [illegible] back on the Medical Council [illegible] in connection with medical aid societies—an attack evidently instigated by those [illegible] who have asserted through [illegible] organs that they will [illegible] obtain an act of Parliament to protect them from "the council." The paper gibes at the council for ignorance of the English language in speaking to [illegible] "infamous in a professional respect." Surely, the writer of such an article should have known that the phrase of which he makes so much, is dictated by the act of Parliament. As to the judicial decisions of the council being upset, he should also have known that the courts have already decided that there is no appeal from its judgments. The charge of trade-unionism leveled at the council is not only absurd, but in a paper which usually sides with the unions in trade disputes, is a little hypocritical. Still more inexcusable is the pretence that the poor will be deprived of medical assistance, and that the workingman may be driven to accept charitable aid from hospitals, etc. The poor have never failed to find free attendance, and the workingman has never failed to avail himself of hospital relief. The pretence that his independence will be sapped if he cannot pay a penny a week for medical aid, is too transparent. But, then, this pandering to the workingman by pressmen is as disinterested as that of the politicians. The one fishes for his dime, the other for his vote.

Drs. F. J. Poynton and Alexander Paine communicated to the Pathological Society, on the 7th, the results of an investigation with a diplococcus from the knee-joint of a man of sixty-seven who suffered from chronic arthritis and who died from accidental poisoning. Several joints were involved, the fluid was clear and scanty, the cartilages eroded, the bones eburnated, the synovial membrane thickened. The diplococcus was isolated and grown on blood agar. Injected intravenously into two rabbits, arthritis followed in both without valvulitis or suppuration in the viscera. One, killed on the fifteenth day, showed no changes of cartilages or bones. The other, killed in the tenth week, had arthritis of the right knee, and the specimen (exhibited) showed the changes associated with osteo-arthritis. It seemed curious that this mono-arthritis was the result of intravenous, not direct injection into the joint. This non-suppurative osteo-arthritis had not previously been observed by Drs. Poynton and Paine in animals inoculated with the diplococcus of rheumatic fever. Cultures and sections showing the diplococcus in unincubated and incubated fragments of synovial membrane were demonstrated, as were other specimens.

Dr. A. E. Garrod remarked that more than one disease was included in the term rheumatoid arthritis. The diplococcus had produced an arthritis, but other micro-organisms might do the same. Dr J. H. Drysdale thought we must not conclude too much from a single experiment. Mr. Shattock asked for more definite history of the patient, as he might have had rheumatic fever, and the organism be a mitigated diplococcus rheumaticus. The cartilage was hardly characteristic, but there was a degree of lipping of the joint. Mr. Spencer asked if gonorrhœal rheumatism could be excluded.

The reply was that fuller history could not be obtained on account of the death from carbolic poisoning, but there was no evidence post mortem of any other disease. Gonorrhœal cocci could be excluded by the difference in form and growth.

The occurrence of malignant tumors in the pelvis originating from suprarenal "rests" was the subject of a paper by Dr A. Eastwood, who showed a specimen which he had examined, and seemed unique. It was a large tumor attached to the fundus uteri, but separated by a capsule. Its character was determined by a process of exclusion and observing that these were typical of a suprarenal tumor. Two other specimens of suprarenal "rest" tumors, growing in connection with the kidney, were shown for comparison. Dr Eastwood remarked on the bearing of these growths to questions as to the internal secretion of the gland, the diagnosis of new growths, and the theories that have been propounded concerning them, particularly criticizing Ribbert's displacement theory.

Mr Targett admitted that the structure of the tumor was typical of one arising from an adrenal "rest." Such growths were to be found in the broad ligament, but were not common. He had only met with them in the stillborn fœtus, never in the adult.

Mr Shattock put little, if any, value on theories of malignant growth. None were more than working hypotheses, and Ribbert's less than most. Referring to Dr Lack's experiment, he considered the growth which followed only a coincidence, for neither Dr Lack nor himself had been able to produce a similar result. Lubarsch and others had equally failed by injecting minute fragments of tissue into the veins. Dr. Eastwood, in reply to Mr. Targett, said that German authors asserted that suprarenal rests might often be found in the broad ligament of infants, if minutely examined.

Radical treatment of chronic intestinal tuberculosis is advocated by Mr. Mayo Robson, who read a paper on the subject at the Clinical Society's meeting last week. He related seven cases in which he had operated with one death. In two there were adhesions, but in the others the bowel was free. In one case, colotomy, in another, short-circuiting, secured physiological rest to the diseased part, and answered so well that, when excision involved serious difficulties, or the patient seemed unfit to bear it, he would adopt similar procedures, and then trust to general treatment and hygienic surroundings. Where peritonitis coexisted with the intestinal disease, and exploratory operation had not arrested the tuberculous process, removal of the principal focus had succeeded; so had short-circuiting. Simple abdominal section often seemed to cure tuberculous peritonitis, but the disease was apt to recur after a longer or shorter interval, and Mr. Robson suggested that this was due to the original focus being left to become the starting-point for a fresh diffusion of tubercle in the peritoneal cavity. If so, the original disease should be removed whenever possible, without adding seriously to the risk of the operation.

Mr. Symonds thought operation was mostly undertaken for the relief of obstruction rather than to cure ulceration, but he mentioned a case in which two feet of intestine had been excised, and another in which short-circuiting had been done. He approved of removing the disease whenever possible.

Mr. Watson Cheyne said short-circuiting was sound practice, but it was doubtful whether it was advisable to search for the original focus; if strictly localized, it might be desirable to do so, but not in diffuse peritonitis, on account of the depressed state of the patient.

Mr. Newton Pitt thought tuberculous appendicitis rare, and that most operations were done in view of obstruction

Mr. Barker agreed that appendix cases were rare. He referred to a case in which cæcum and colon (ascending, transverse, and descending) had been successfully excised for tuberculous ulceration, the patient completely recovering.

Dr. Percy Kidd thought that there was often concomitant disease of the lungs, and the diagnosis of ulceration in the early stage was difficult. Multiple ulcers he had met with in the cæcum more frequently than in the ileum.

Mr. Keetley and Dr. Dalton mentioned cases, and then Mr. Robson, in the course of his reply, said that 5 per cent. of 300 cases of appendicitis on which he had operated proved to be tuberculous.

OUR PARIS LETTER.

(From Our Special Correspondent.)

METHYLENE BLUE IN TONSILLITIS—BACILLI IN THE BLOOD IN TYPHOID FEVER (COURMONT)—THE USE OF ELECTRICITY IN THE TREATMENT OF SPRAINS—ADULTERATION OF MILK IN PARIS.

PARIS, January 17, 1892.

AT a recent meeting of the Medical Society of the Hospitals, Professor Chauffand spoke of a novel form of treatment of Vincent's angina, which is a disease characterized by a fœtid ulceration of the tonsil in the form of a chancre, high fever, and painful swelling of the lymphatic glands. Three applications of perfectly pure methylene blue cured this patient completely. This treatment would seem to be a good method of recognizing this disease and distinguishing it from syphilis.

Recent investigations have shown that Eberth's bacillus is found in the blood in most cases of typhoid fever. Dr. Courmont, who has been examining the blood in typhoid fever, has found it generally before the fifth day. It remains in the blood until the end of the third week. There is no relation between its presence in the blood and the agglutinating power of the serum.

In some cases the sero-reaction may be retarded, though bacilli may be already found in the blood. At least 2 to 4 c.c. of venous blood should be mixed with 5 c c. of bouillon to produce a culture.

The treatment of sprains has seemed to consist of late in the use of massage, but several authors have been advocating recently in France the use of the electric current. Even massage is not applied in many cases in any but a perfunctory manner. A certain number of English authors have recommended the use of electricity, but without giving special instructions.

Charrier and Planet indicate the treatment that was recommended by Apostoli, and which consisted in faradization with an apparatus having a bobbin with a fine wire, and allowing of very rapid intermissions. The electrodes used are two large tampons covered with chamois skin and made out of coal. The positive pole is generally placed over the internal malleola, while the negative one is moved over the affected surface. The "séance" should last about five to ten minutes. The most remarkable result of this treatment is the well-nigh total disappearance of pain after the electrical application. The patient is able to get up and walk.

The last census taken in France in 1901 has shown that during the last five years there has only been an increase of 444,613 inhabitants. Still this is better than in 1896, when the increase was only 175,027. If, however, the statistics published in other countries are considered, it is seen that France is falling rapidly behind the other nations. Germany increased well-nigh 7,000,000, Austria-Hungary almost 4,000,000, and Great Britain 4,721,000 during the space of ten years, while France only had an increase of 619,000. Another result of the census is to show the steady influx of the country people into the city.

The *Matin*, a Paris daily with a large circulation, has been carrying on a campaign against milk dealers. According to this paper only a small amount of milk is quite pure when it is bought from the retailer, it having been more or less falsified as it passed through the hands of the producer and middleman. There are in reality four intermediaries, which are the producer, the agent who collects the milk and sends it to Paris, the milkman who brings the milk to the shop, and the owner of the shop where it is sold. Milk that cost only nine to eleven centimes or two sous, is sold at eight to twenty in Paris. The *Matin* pretends that some of the middlemen make as much as 10,000 to 20,000 francs a year, and it calls upon its readers to found a league of public health, which will prosecute all dealers who change the quality of the milk. There is a rumor that a large establishment for the sale of milk is soon to be opened in Paris, and this recent campaign of the *Matin* would be really after all only a sort of puff for this.

MEDICAL PRACTICE LAW IN HAWAII.

To the Editor of the Medical Record:

SIR: I see in the MEDICAL RECORD, No. 1,624, the requisites for license in most of the States. I should like to add our own to the list. As the result of our law the only irregulars here are an old Portuguese, who has been here many years, and a few Chinese who also antedate the law, and certain *Kahunas*, or native practitioners, similar to the Indian Medicine-man. Our population is indeed most heterogeneous, some 60,000 Japanese, 29,000 Chinese, and 22,000 Portuguese. There are several reputable Chinese M.D.'s and a large number of Japanese, all of whom compare fairly with our own men.

The law is stringent, requiring every practitioner to undergo examination before a Board of Three. The examination is a thorough one, and no one is licensed who cannot pass a reputable examination for a degree. The fee, paid to the Board of Health, is $10, and a voucher as to morals is also required.

The law has been in operation four years, and is very satisfactory.

GEO. P. ANDREWS,
Chairman of the Board of Examiners.

HONOLULU, January 4 1902

THE CHIEF HORROR OF SMALLPOX.

To the Editor of the Medical Record:

SIR: Only yesterday one of the leading daily papers of New York City, the *Herald*, very properly directed attention to the "chief horror of smallpox." It consists not in the disease itself, but in the way the unfortunates who are attacked with it are taken care of, by reason of the laws now governing the Health Department of this city. As soon as a case is recognized as one of smallpox, the patient is transported to North Brothers' Island. If the case is a suspicious one, the patient is taken to the Reception Hospital for Contagious Diseases, until the diagnosis is definitely determined. These rules have been established, and are carried out for the public good, even though it is clear that great mental distress is caused not only to the patient, but also, and in greater measure, to the nearest relatives. Let me ask, is the law as it now exists either right or necessary? I do not believe it is. In the first place, the only persons who contract real smallpox are those who have *not* been successfully vaccinated. Those who have been successfully vaccinated may take varioloid, but they do not take smallpox. They take in reality a very mild and never fatal form of disease. The reason why such persons are isolated is merely because they can give smallpox to those persons who have not been successfully vaccinated. Are the former persons, then, to be made victims of the law because silly, ignorant, unscrupulous people will not partake of the only protection to them from a dreaded disease. In my mind that is not right or just. Again, vaccinia is no more contagious than scarlet fever or measles, and is not, in reality, as grave a disease as either. Why, then, not treat it with just the same precautions and under the same conditions that we treat the latter? I see no reason why not. The law of New York City does not at present make it compulsory to be vaccinated or revaccinated at stated intervals. In my judgment, the law should be made compulsory, and the process the same for all. In Germany, where such a law is compulsory, there is practically no smallpox. The great and urgent importance of this subject prompts me to write this letter.

Beverley Robinson, M.D.

42 West Thirty-seventh Street.

Progress of Medical Science.

The Boston Medical and Surgical Journal, Jan. 30, 1902.

Vaccination and Smallpox.—S. H. Durgin holds that we do not vaccinate enough. To secure full vaccination, a child should not only be vaccinated when very young, but the physician should feel called upon to exhaust all susceptibility to smallpox by repeating the operation until it will no longer take effect. At the age of ten or twelve years this process should be repeated to the same extent. Later in life, on exposure, vaccination should be repeated. The data in Boston furnish evidence that, as a rule, the unvaccinated die and the vaccinated get well. The author has been unable to satisfy himself whether the occurrence of smallpox among those who have been vaccinated depends upon our carelessness in vaccination or upon any possible deterioration in the bovine lymph which has been in almost exclusive use for the past thirty years. The question should be carefully studied. There should also be a more uniform and careful method of vaccination. Aseptic conditions are necessary, scarification one-eighth to one-quarter inch in diameter is ample, the drawing of blood is useless, and care in rubbing and drying in the lymph is important. The shield is a nuisance. If, at the end of a week, there is not a typical vesicle, the operation should be repeated.

Suggestions in Medicine.—George C. Smith urges that greater attention be paid to the psychical side of their patients than is at present the case. Children are peculiarly susceptible to suggestion, and there is no doubt that early training would save many a person from hysteria, neurasthenia, or insanity later in life—diseases which are quite as often acquired as inherited. Patients are usually in a receptive mood, but if at all pessimistic or melancholic, are more open to evil than to good suggestions, hence the necessity of using great caution in the method of examination not to arouse apprehension, as well as care in our suggestion of remedial therapeutics. The pernicious influence of evil suggestion is clearly illustrated in cases of traumatic neurosis—the victims of railroad accidents, who are still further victimized by sympathizing friends and impecunious lawyers, till they become imbued with fixed ideas that are false. The use of wise suggestion necessitates in the physician a more thorough study of human nature and of psychology, makes the examinations more exhaustive, sharpens observation, broadens vision, enhances the powers of concentration, and intensifies interest. The result is better diagnosis, prognosis, and treatment.

Journal of the American Medical Association, Feb. 1, 1902.

Nineteen Years' Experience with Creosote in Tuberculosis.—J. A. Burroughs presents the following conclusions: (1) Selection of a creosote made by the double distillation of tar from beechwood is essential. (2) Large doses continued indefinitely do not irritate the stomach, but improve digestion. (3) Large doses are appropriated by the system, as shown by clinical observations. (4) The drug in large doses is indicated in all stages of the disease. (5) For permanent results the drug in large doses should be continued for months after the absence of all physical signs or constitutional disturbance. (6) Creosote in large continued doses is not only the most rational treatment, but gives the best clinical results of any one agent familiar to clinicians.

Treatment of Acromegaly with Pituitary Bodies.—After a discussion of the literature of lesions of the pituitary gland, and their relation to the normal physiology of the body, Sidney Kuh reports three cases of acromegaly—one in a Jewish tailor, twenty-nine years old; another in a Swedish woman thirty years old, and the third in a Jewish merchant, fifty-eight years old. Concerning the general effect of treatment with the remedy mentioned, Kuh states that the result in his three cases was that the first patient derived little, if any, benefit from it, while in the other two cases for one and a half and one year respectively, the condition of the patients' mental disability improved. Headache, dizziness, general weakness, hypochondriasis, and vomiting disappeared, while the trophic changes in the face of the second patient became very much less marked. In her, new symptoms appeared, however, almost as troublesome, perhaps, as those from which she had been relieved. Still when one remembers how little other methods of treatment can do in this disease, even the slight improvement obtained seems gratifying. The most important question is whether the feeding with pituitary bodies exerted any beneficial influence whatever. This question, for two cases at least, is to be answered in the affirmative.

Dyspeptic Asthma.—Max Einhorn reports a group of thirty-one cases of asthma in which the chest organs were apparently in a normal condition. The cases are divided into acute and chronic. The first group is characterized by the occurrence of attacks of asthma at more or less prolonged intervals, either without an apparently preceding cause or after distinct excesses in eating, drinking, smoking, or after undue excitement. The attack is usually of a very severe type, often assuming alarming symptoms—extreme dyspnœa, cyanosis, almost collapse. The second group, that of chronic dyspeptic asthma, embraces the larger number of cases, and may again be divided into two separate categories: (*a*) Cases in which the attacks of asthma appear quite soon after meals, either without any particular provocation or after some slight exertion; (*b*) Cases in which the attacks usually occur two or three hours after meals, either spontaneously or again after some exertion—walking, etc. In a certain number of the latter category the attacks can be checked by partaking of a small amount of food. Cases belonging to category (*a*), of group 2, resemble very much true angina pectoris, which is so often encountered in arteriosclerosis of the coronary arteries. Their differentiation from the latter is often difficult. For even in true angina pectoris at the beginning, there will be attacks without any discoverable lesions of the heart or blood vessels. Such cases may for a long time appear as dyspeptic asthma, until all of a sudden there are distinct signs indicating the heart involvement, as, for instance, a sudden appearance of albumin in the urine or irregularity of the pulse, etc. The treatment must be directed, first, toward relieving any existing disorders of the digestive tract; second, toward correcting any abnormal position of the abdominal organs, principally the liver. A regular mode of life, avoidance of too much tobacco and alcoholic drinks, also of too much mental worry and strain, is always of importance. By paying attention to these points, the majority of cases of dyspeptic asthma will not only be temporarily relieved, but often radically cured.

New York Medical Journal, February 1, 1902.

A Case of Hydrencephalocele.—D. E. Wheeler reports the case of a child presenting no abnormality except a large tumor protruding from the posterior fontanelle. It was twelve inches in circumference and covered with skin which was hairy near its attachment to the head. The tumor was translucent and markedly fluctuating. Fluctuation was not communicated to the anterior fontanelle. The child gradually sank, while the tumor, in the mean time, increased in size and became more tense. There were no symptoms of digestive disturbance, nor any convulsions, even when the tumor was compressed. On the twenty-fifth day after admission, the child collapsed suddenly, and died with dyspnœa and cyanosis. Post-mortem examination showed the anterior fontanelle open, cranial bones soft, with numerous small islands of membranous bone-formation, mingled with areas where there was no calcification. This condition was best seen in the parietal bones, on inner surfaces of which were small concavities corresponding to the uncalcified areas. The sinuses and brain tissue appeared normal. From the posterior fontanelle there was a large fluctuating cystic growth, but fluctuation was not communicated to the anterior fontanelle. This cyst was seventeen inches in circumference, translucent, and contained clear serum. Pressure forced the cyst contents into the posterior cornu of the left lateral ventricle.

Typhoid Perforation; Its Frequency, Prognosis, and Treatment.—H. M. Taylor is inclined to regard as true the prevalent statement that one-third of the deaths in typhoid fever is due to perforation, though this fatal complication may have often been unrecognized. Cases in which a diagnosis of perforation has been made, and in which recovery occurred, were probably cases of local peritonitis and incomplete perforation. In the light of our present knowledge, surgical intervention offers the only hope of recovery. In this the profession is pretty well agreed, but the difficult point is to decide when perforation has actually occurred, for the clinical picture of this condition as portrayed in the older textbooks is by no means universally true. In many cases, the patients are perfectly clear mentally; they can warn us intelligently of the sudden onset of pain, and can help us to decide when it is localized or diffused. In many, the thermic changes are gradual and no sudden rises or falls occur, and the same is true of the pulse. In many, abdominal pain is absent, and there may be no distention or rigidity. In this class of patients, and they are by no means a minority, such a group of symptoms as vomiting, pain, shock, increased and increasing pulse rate, abdominal rigidity, distention, and abolished peristalsis and gaseous movement, together with, perhaps, a reduced temperature incident to shock, should enable us to make about as positive a diagnosis as is possible in a majority of acute intra-abdominal troubles. On the other hand, in another group of cases, in which there is mental apathy, not infrequent vomiting from impaired stomach digestion, distention from nerve exhaustion and intestinal indigestion, rapid pulse, high temperature, frequent paroxysms or persistent pain from peritoneal involvement without perforation—in such cases the diagnosis must call for an acute reading of symptoms manifested. The author would attach especial importance to pain, muscular rigidity, and inhibited peristalsis, as diagnostic points.

Medical News, February 1, 1902.

Sanitary Aspects of Nicaragua vs. Those of Panama.—J. Edward Stubbert believes that the following conclusions are supported by reliable statistics: The natural conditions of the Central American or Nicaragua route are far more conducive to health than those along the Isthmus of Panama route. The endemic diseases of the Panama route are far more fatal than those along the Nicaragua route. During the time of actual construction, while there would necessarily be an increase of sickness, the mortality would be markedly less in Nicaragua than in the Isthmus of Panama. After the completion of the canal, the regions bounding the Nicaragua route would be capable of development by the Anglo-Saxon, while he could not safely live along the Panama line. The writer adds that far more money was spent *per capita* by the medical department of the Panama Company than by that of the Nicaragua Company, and yet the morbidity statistics were greatly in favor of the latter.

A Word on Specialization in Medicine and Surgery.—Wm. M. Polk declares that the problems which the physician has to face are of such a nature that his work in the interest of the patient can be specialized to only a limited degree. The only real specialty in medicine is neurology, and this is so on account of the great influence of the nervous system, and of the need on the part of the physician of wonderful patience in the management of people in whom will-power can often not be counted on as an element in their cure. As to the surgeon, he must be an anatomist, a physiologist, and a pathologist. He must know in what cases to interfere, and he must recognize those cases in which the patient can master the situation himself. He must be thoroughly familiar with the reparative forces of the body. The entire field of surgery is enormous, as can be realized when it is seen in how many conditions surgery has supplanted medicine. Consequently, in surgery it is more essential than in medicine to make some division of the field. That specialty will survive, whose results are better as regards the patient than are shown in the general field. Limitations of specialization, then, will be fixed by results. The tendency of all specialization is to narrowness and to exaggeration of minutiæ. The curse of the profession at present is the non-competent specialist.

American Medicine, February 1, 1902.

The Passing of Drug-Giving.—John Madden states that drug-giving as a function of the physician is fast decreasing in importance. Some years ago, every disease had its treatment indicated in sets of formulas. Later, there arose the hope for specifics. A few were found, among them mercury and cinchona bark. The discovery that most diseases are caused by germ invasion practically left the profession without any rational remedy for any disease except those for which specifics had been discovered. Rational treatment would mean a medication which, while being harmless to the organism, would, nevertheless, destroy the germs of invasion or render the poisons generated by them inocuous—a germicide or an antidote. We are even yet sadly lacking in rational remedies for the cure of disease. There is something to be hoped for in the production of antitoxins, for by their natural development nearly all acute febrile diseases are made self-limited. In this method great success has been attained in diphtheria. These results, as well as those attending vaccination with the kinepox as a protection against smallpox, and of the treatment of persons bitten by rabid animals with increasingly potent rabic virus, have stimulated hope for the treatment of other diseases by kindred methods. There is always hope that chemistry may unlock some of these secrets, but at present the realization of such a hope seems far distant, for there are many perplexing problems to be solved. However, it is certain that the early polypharmacy will not be revived.

The Abandonment of Digital Examination by the Vagina in Labor.—W. A. Briggs describes the methods of digital examination per rectum and palpation of the perineum. After cleansing and disinfection of the vulva and adjacent parts, the patient should be placed on her back, with the knees well flexed, close to the edge of the bed; the examiner must sit beside the bed on a low chair, facing the patient. The disinfected and gloved right hand is to be passed under the patient's right knee, the index finger being passed into the rectum, its tip being carried, if possible, to the sacral promontory, and the tip of the thumb to the pubic synchondrosis; by their divergence one may estimate the conjugate diameter. Then the left hand is placed on the abdomen just above the pubis, and by gentle palpation, it will be possible to map out the presenting part and determine its size, position, descent, mobility, and stage of evolution. If the head presents, the accoucheur should dip the fingers of the left hand down about the chin or the occiput, and the position may be determined even if the fontanelles and sagittal suture cannot be felt. The os and the cervix are to be searched for with the tip of the finger. The sagittal suture and fontanelles should be identified. Should the head recede before the examining finger, it may be fixed by the left hand from above. Palpation of the vulva and perineum will determine the mobility and the progress of the presenting part, and obviate the necessity of internal examination. The writer believes that abdominal palpation and auscultation, antepartum pelvimetry, digital examination per rectum, simple and bimanual, and palpation of the perineum intelligently and systematically practised, will, in all but operative cases, obviate the necessity of invading the vagina in any way.

Philadelphia Medical Journal, February 1, 1902.

Treatment of Epithelial Skin-Cancers and Sycosis Non-Parasitica with the X-Ray.—J. F. Rinehart speaks of the advantages of the treatment of these cases by the *x*-ray. It gives no pain, there is but little scar tissue left after the sore has healed, and there is the possibility of a more thorough eradication of the disease, as the effect of the rays is to destroy all the cancer cells within the area exposed. He reports a number of cases which illustrate the success of this treatment. It is best not to be in too great a hurry to obtain the reaction lest too much inflammation be caused. There is a great difference in skins as to their ability to withstand the *x*-ray. It is best to begin with a five-minute exposure at six or eight inches and try that for a day or two, and if no reaction is obtained, increase the time of exposure till the desired effect is produced.

Precancerous Keratosis, Probably Due to X-Rays.—James C. Johnston believes that every squamous-celled epithelioma has a stage in which the only change is a thickening of all the layers of the surface epithelium. There is not only a hyperkeratosis, but an acanthosis, or overgrowth of the prickle-cell layer, as well. He reports two cases, the first one being in the early stages of the disease of which the second one shows the full development. The latter patient had worked with the *x*-ray machine for four or five years. The backs of both hands were affected as far as the wrist joint. The skin was rough, dry, and slightly scaly, with a little itching. There was no pain and no thickening. The palms were rough, dry, and thick. The nails showed dystrophic changes. The chief feature was about twenty hard cornified growths on the backs of both hands. The larger keratoses all showed a small circumscribed area in the center, where the horny material had crumbled away, leaving a rough blackened pit. Microscopical examination showed the malignant character of these growths. Rest and treatment were advised. There has been no progression of the lesions, and the epithelioma which was excised has not returned.

The Lancet, January 25, 1902.

The Widal Reaction in Tuberculous Meningitis.—Edward Mackey reports the case of a woman of twenty-eight years in whom the diagnosis of typhoid fever had been made, mainly on the strength of a positive reaction to the Widal test. The patient died and autopsy revealed no typhoid lesions, but distinct tubercles in the brain.

A Case of Vagina Duplex.—The condition noted in the case reported by E. W. Sharp came to light during an operation for hemorrhoids. The vagina was divided by a fleshy partition running from before backward, and from the anterior [illegible] of [illegible]. In the [illegible] it was [illegible] half an inch thick. The opening [illegible]. There was [illegible] between the two portions of the tongue. The [illegible] was small, distinct [illegible] were absent, and the [illegible] attached on the left side. The [illegible] was [illegible] normal. There was no [illegible] difficulty. The patient, [illegible] years, was [illegible] improvement.

Combined Fetal and Maternal Dropsy.—H. V. Munro reports the case of a woman aged thirty-one years who suffered from dropsy of the lower limbs and abdomen, the latter being so much swollen as to suggest hydramnios. Her confinement was expected to occur on November 25, but labor began on October 11, two days after she was seen by the writer. The os being dilated, the membranes were ruptured, but only half a pint of liquor amnii escaped. Examination revealed high up a boggy mass giving exactly the sensation of a hydrocephalic head. Forceps was applied and the head delivered. It looked at first like an acephalic monster, no features being discernible; but subsequent examination showed that the shape was due entirely to anasarca. The delivery of the body was retarded, and it became necessary to place the patient under chloroform when, with much difficulty, the body of an enormously dropsical dead fetus was extracted. The uterus was still quite as large as a full term organ, due to the fact that the placenta was œdematous and as large as four or five ordinary placentæ put together. There was no unusual hæmorrhage. The mother made an uneventful recovery. The fetus was anasarcous throughout. Section revealed fluid in both abdomen and thorax.

The British Medical Journal, January 25, 1902.

A Note on the Diagnosis of Yellow Fever.—St. George Gray from his study of the subject concludes that in yellow fever there is a slight increase in the number of large uninuclear leucocytes, but that this increase is by no means so great as it is in malaria. The lowest percentage of large uninuclear leucocytes that he has observed in malaria is nineteen, while it has gone as high at times as thirty-six. Although in the cases of yellow fever which he examined, he counted many doubtful leucocytes among the large uninuclears, he could not bring the percentage above eleven.

Leprosy and Congenital Symmetrical Keratoderma.—George Pernet refers to a case reported by Gilbert White as a leper, which the writer declares comes rather under the category of symmetrical congenital thickenings of the palms and soles. This affection is described as affecting only the palms and soles. It was a scaly eruption, and broke out usually twice each year, spring and fall, and by peeling away left the skin so thin and tender that neither the hands nor feet could perform their functions. Neither of the parents was a leper. An intermittent case of this kind is also on record. A similar condition—hereditary palmar and plantar keratoderma—is frequent on the Island of Meleda (Dalmatia), and such cases were also formerly mistaken for leprosy. It is noteworthy that this case was not hereditary. Leprosy is unheard of as involving the soles and palms alone.

The Treatment of Dysentery by Rectal Injections.—Cecil F. Lillie has found this method most useful. The injections have never proved displeasing to the patients. The pain which was sometimes suffered at first was soon overcome by allowing only a small quantity of the solution at a time to pass into the bowel slowly. The value of injections in chronic cases is well known. They are also valuable in mild acute cases. The bowel is flushed out and the toxic substances are removed, and with their removal the griping and tenesmus, which they induce, subside. Antiseptics may be in this way directly applied to the focus of the disease. In addition to the injections the patient must be kept in bed and take fluid nourishment in small quantities at frequent intervals. Milk diluted is best. Chicken broth is often useful. Stimulants are generally required.

Blackwater Fever.—R. U. Moffat states that the whole theory of the influence of quinine in causing hæmoglobinuria rests on the fact that in the majority of cases there is a history of quinine having been taken. But this fact proves nothing, if it is remembered that in tropical countries practically everybody takes quinine. The writer believes that blackwater fever is due to a chill acting at a certain stage of the development of the parasite in a patient predisposed by acute or chronic malarial infection. The important point is the practical one that with malarial patients, especially those who have been much exposed to infection, the greatest care should be taken to avoid a chill during the apyretic stages. Whatever may be the exciting cause of the hæmoglobinuria, the writer believes the cases which are most apt to cause [illegible] are those in which no quinine has been given before the chill. The theory that hæmoglobinuria is due to the use of quinine, the writer thinks, is productive of great harm to patients suffering from malaria.

Münchener medicinische Wochenschrift, Januar 14, 1902.

Purpura Hæmorrhagica in Pulmonary Tuberculosis.—W. Rosenbach reports a case of this complication which he thinks was brought about by a reabsorption of the toxins of the tubercle bacillus. The patient was twenty-five years of age, and gave the ordinary history and physical signs of phthisis. The hæmorrhagic spots were present at first upon the forearms and dorsal surfaces of the hands, but later they also appeared upon the upper arms and shoulders. Slight hæmoptysis was present. The purpura remained with varying intensity for about four months, at the end of which time the spots began to disappear. Although a year has elapsed, no recurrence has taken place.

Gangrene Following Scarlet Fever.—R. Seubert reports a case of mild scarlet fever in which gangrene appeared as a sequel. The latter first appeared on the anterior surface of the left thigh, and rapidly increased in severity, so that in the course of two weeks, in spite of appropriate treatment, the greater part of the left lower extremity became involved. Amputation was performed. Two days thereafter a gangrenous spot appeared on the right thigh. This, however, yielded to suitable treatment, and recovery followed. A bacteriological examination of the amputated limb showed a pure culture of the streptococcus. It is interesting to note that in this case, as well as in those previously reported by Kohlhorst and Holmes, the left lower extremity was the region principally affected.

Behring's Latest Diphtheria Theory.—Fritz Schanz considers the most recent views of Behring in regard to the etiology of diphtheria. Behring now holds that true and false diphtheria bacilli, including the xerosis bacillus, are identical. He founds the view upon the ubiquity of the diphtheria bacillus, and the fact that investigation has shown that the serum of individuals who possess pseudodiphtheria bacilli on their mucous membranes is antitoxic against infections produced by true diphtheria bacilli. Schanz has for several years maintained this same view. According to this idea, much of the immunity to true diphtheria is produced by a previous infection with pseudodiphtheria bacilli. Endeavors, therefore, to separate true and false diphtheria bacilli are useless, for they are interchangeable, and the presence of one or the other variety is dependent upon the soil upon which they are grown. Observation has also shown that true diphtheria bacilli produce in human beings not alone the ordinary local lesions of diphtheria, but various other conditions, such as rhinitis atrophica chronica and pharyngitis sicca.

Relation of Langerhans' Islands to Diabetes Mellitus.—M. B. Schmidt endeavors to throw some light upon this interesting and at present much-discussed question. He reports twenty-three cases of diabetes mellitus in which the pancreas was examined post mortem. In eight of these, this organ was entirely normal, and in seven the localized inflammatory changes were so slight that it was not probable that they stood in a causative relation to the disease. In one the pancreas was markedly atrophied, but otherwise contained no pathological lesions. In the remaining cases the islands of Langerhans were diseased. The lesions found can be classified under three heads: (1) Hyaline degeneration; (2) Acute interstitial inflammation; (3) Chronic interstitial inflammation. This may be either interlobular or intralobular (interacinose) in character. The latter is the more common form. From this it would appear that in many cases diabetes mellitus is dependent upon well-defined lesions in the islands of Langerhans, but that such are in no way to be considered as pathognomonic of the disease.

Berliner klinische Wochenschrift, Januar 13, 1902.

Incandescent Electric Light in the Treatment of Internal Infections.—Dr. Krebs has undertaken a series of investigations, in order to ascertain the value of the incandescent electric light in the treatment of infectious diseases. He first observed the effect of such light upon healthy mice and guinea-pigs, and showed that upon such animals no deleterious effects were produced by this treatment. Some of the animals were then inoculated with anthrax bacilli, while others were maintained as controls. In a number of experiments some of the infected and non-infected animals were exposed to an electric light of fifteen candle-power, while the others were not so treated. Some of these investigations were carried on at the room, and others at the incubator temperature. The results showed that the light treatment had no effect in lessening the duration or severity of the infection, and the author believes that, however strong the bactericidal power of light upon microbes under artificial cultivation may be, it is certain that no such effect is produced when the organisms are present in the animal body.

Relation of Angina to Articular Rheumatism, Erythema Nodosum, Pneumonia, Scarlatina, and Measles.—In considering the relation from a bacteriological standpoint of angina to these diseases, Menzer says that there is abundant evidence to show that the tonsils normally offer resistance to bacteria in their endeavors to gain an entrance into the system, and that when general infection occurs from the throat the organisms gain admission through the mucous membrane which surrounds these organs. So far as articular rheumatism is concerned, there is much testimony to show that identical streptococci are present both in the throat and in the affected joint, and it is believed that here the throat has been the portal of entry for the infecting agent. The same may be said of erythema nodosum. A case is reported in which a staphylococcus was isolated from both the cutaneous lesion and the throat of the patient. With regard to pneumonia, it may be said that the idea of direct inhalation infection is improbable. Animal experimentation has shown that by inhalation small particles do not reach the terminal bronchi or alveoli. Pulmonary tuberculosis, which has been demonstrated to be due to direct inhalation infection, in the majority of cases, usually affects the upper lobes while pneumonia usually affects the lower. Furthermore, when we consider the symptomatology and pathology of this disease, and the fact that pneumococci are found in the throats of pneumonia patients, it seems reasonable to suppose that the organisms gain admission to the lungs by way of the blood vessels, the throat having been the portal of entry. Thus far, investigators have been unable to find any specific bacteria in scarlatina and measles. When we consider that in these diseases the mucous membrane of the throat and nares is always affected previous to the outbreak of the constitutional symptoms, it is fairly probable that the causative agents gain entrance to the system through these structures. The question now arises whether a specific microorganism is nesessary for the production of the diseases here considered. Modern bacteriological thought is more and more drifting away from the specific microbe to the peculiar individuality of the infected person. This has been brought about through the knowledge that certain bacteria supposed to be specific for given disease may, in reality, in different individuals, give rise to a variety of clinical conditions, some of which are totally different in symptomatology from the supposed specific disease. Furthermore, organisms thought to belong to other species, many of which are saprophytes, may produce conditions which cannot be differentiated clinically from the specific disease. In accordance with these facts, Menzer advances the opinion that there are habitually present in the throat a number of microorganisms which cause no trouble so long as the insusceptibility of the individual remains intact. When, however, this, from any cause, is broken down, they invade the system and produce disease. Now, the disease so produced may vary in character according to the constitution, either inherited or acquired, of the patient. The author brings forward no tangible proofs of his theory, but merely advances it as a hypothesis by means of which many hitherto inexplainable facts may be made clear.

French Journals.

A Case of Myoclonus Multiplex.—Ingelrans reports the case of a patient aged twenty-six years, who had an attack of typhoid fever. During convalescence, muscular contractions of the right side, which had existed before the typhoid fever, indeed, since the age of six years, reappeared. When these twitchings first appeared they had been attributed to chorea. Ingelrans states that they cannot be due to chorea nor to athetosis; they are exactly like those produced by the electric current. He believes that this is a case of myoclonus multiplex of Friedreich.—*Le Nord Médical*, January 15, 1902.

Latent Syphilitic Aortitis and Visceral Neuralgias.—M. L. Rénon describes a case of syphilitic aortitis which manifested itself by very painful crises, which were limited to the viscera, and which completely simulated the violent pain of biliary and renal colic. The presence of aortic insufficiency which had not existed a year before, established the diagnosis. This was verified in a decisive way by the institution of antisyphilitic treatment which rapidly put an end to these painful crises. There was no physical sign of aneurism. The cause of the violent visceral pain is not easy to determine.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, January 16, 1902.

Death by Chloroform.—Poirier reports a case of death by chloroform. The patient, a woman of sixty-three years, afflicted with a neoplasm of the stomach, had been under his charge for some time. She had reached the stage of extreme cachexia. Chloroform was given to her most cautiously, and when she had become unconscious, and the operation had proceeded to the point where the stomach was found to be adherent on all sides, and just as the liver had been separated in order to allow of an anastomosis, the patient appeared to revive. A few more drops of chloroform were administered, but the pulsations of the gastrohepatic artery ceased, and the respiration stopped. The beating of the heart stopped suddenly twenty-five minutes after the beginning of the operation. The ordinary means of restoring respiration were tried in vain, for the heart was flaccid. The cause of death was not clearly ascertained. The anæsthetizing was well done, but the patient was extremely feeble.—*Le Bulletin Médical*, January 18, 1902.

Lavage of the Stomach in the Infant.—M. L. Babonneix states that the temperature of the liquid used in this proceeding is most generally lukewarm, although it is varied according to the condition of the patient. If there is tendency to collapse and the temperature is below normal, the liquid may be 37° or 38° C. If, on the contrary, there is fever, the liquid used may be cool. It is difficult to state definitely any fixed quantity to be used, as the process is continued until the water returns limpid. The solutions used also vary according to the case. These washings are kept up every day, at least during the acute stage of gastroenteritis; but they ought not to be indefinitely prolonged. The time for lavage is at the end of the period of digestion, that is, as a rule, two hours and a half or three hours after a feeding. Accidents from this procedure are very rare. The effects of lavage are especially mechanical: evacuation and cleansing of the stomach, diminution of the fermentations, etc. Still more, lavage excites reflex intestinal contractions, contractions of the muscles of the abdominal wall, and hypersecretion of all the glands of the digestive tube.—*Gazette des Hôpitaux*, January 14, 1902.

Therapeutic Monthly, December, 1902.

Cause and Treatment of Car-Sickness.—J. N. Rhoads believes that not every person with astigmatism has car-sickness, but that every one with car-sickness has astigmatism. The gravity of the case does not seem to be proportional to the extent of the ocular defect, but rather the reverse. Some prophylactic hints for car-sickness are: Keep the eyes closed during the entire ride or else sit at the end of the car, and look out of the front or back windows, and wear very dark glasses or green shades; the best prophylactic in *steam* car-sickness is to ride backward in the rear seat of the rear coach. The writer does not believe that car-sickness can occur in a person with normal eyes, nor in one who is wearing properly fitted glasses. Concurring indigestion will be cured with the car-sickness. All cases of violent headaches should be refracted, as well as all cases of persistent indigestion and of car- and seasickness.

Tent Life and Simplicity in Therapeutics as Factors in the Treatment of Phthisis Pulmonalis.—Wm. K. Robinson describes a colony for the tuberculous, not far from Denver. The tents are arranged around a central building connected by canvas vestibules. A large coal stove in the center of the house gives facilities for dressing and sitting room. The beds are warmed with hot-water bottles; blankets instead of sheets are used; pajamas are made of heavy flannel with feet and hood. After the weather settles the patients live entirely in their tents, so separated that they do not annoy one another by coughing. Cheese-cloth is used instead of handkerchiefs. The tents have board floors and sides, two feet high. There is always perfect ventilation, and direct sunlight falls upon the contents by day. Fresh air and appropriate diet and hygiene are the principal elements for the restoration of health. Simple drugs are used, such as may stimulate the weakened digestion and circulatory functions; also incidental drugs to regulate excretions and secretions, as the case may require from time to time. There is abstinence from drugs alleged to be specifics.

The Effect of Nitroglycerin in Vascular Disturbances of Some Functions of the Brain, with Reports of Two Cases.—Alfred Gordon declares that in nitroglycerin we have a powerful drug for controlling any functional inhibition of the higher centers depending upon the circulation. It should be used chiefly when a rapid effect upon the vascular apparatus is desired. It quickly dilates the arterioles, thus lowering the arterial tension, increasing the pulse-rate, and reducing the blood-pressure. The results are more promptly obtained from this drug than [illegible] The problem of [illegible] [illegible] that the [illegible] [illegible] ... On the other [illegible] to illustrate [illegible]

The Practitioner, January, 1902

Prognosis and Treatment of Dilated Heart as the Result of Overstrain and Exercise.—[illegible] the right [illegible] [illegible] treatment [illegible] in giving up [illegible] muscular exercise [illegible] a moderate [illegible] exercise in the open air. Sculling [illegible] and in a short time golf and [illegible] may be indulged in, provided that they are [illegible]. It is probable that the heart [illegible] never quite recovers its original strength.

Dilatation of the Heart in Children.—Eustace Smith [illegible] the heart dilates [illegible]. The dilatation may be treated quite apart from [illegible] and is due to blood pressure in a flabby, [illegible] or degenerated heart. It occurs in anæmia, in [illegible] of rapid growth with cold extremities and poor [illegible], in bronchopneumonia, in the [illegible] fevers, and in allied septic states. It is especially apt to occur in diphtheria, acute rheumatism, and influenza. Treatment should consist in a continuation of [illegible] for the disease in the course of which [illegible]. If sodium salicylate is [illegible] there should be added five or ten grains of [illegible] to counteract [illegible] lowering effects [illegible]. Iron and strychnine should be our [illegible] must not be forgotten.

Points in the Prognosis and Treatment of Hypertrophied and Dilated Heart.—Arthur [illegible] prefers to [illegible] as a therapeutic measure. [illegible] and steady it, but are not without danger [illegible] given to patients [illegible] with [illegible] badly. In a visit to Nauheim [illegible] of climate and [illegible] brought by hopeful [illegible]. Rapidity and irregularity due to organic valvular disease are greatly improved by digitalis and [illegible], but when there is no valvular disease, strychnine and the [illegible] are better. Cardiac tonics are of little use if the blood pressure is unduly high. Generally [illegible] it is more important to lessen the heart's work by lowering pressure than to stimulate the heart [illegible]. The larger the heart, especially if the [illegible] of its muscle is doubtful, the more should [illegible].

Hypertrophy and Dilatation of the Heart.—Thomas Clifford Allbutt has [illegible] himself of the [illegible] of the heart due [illegible] to physical exertion [illegible] we have little evidence that a heart [illegible] hypertrophied and dilated will degenerate [illegible] as in valvular disease [illegible] increasing beyond its possible [illegible]. We have indeed learned that in certain morbid [illegible] of the heart the skilful use of a carefully graduated system of muscular gymnastics may be restorative to the heart even at such disadvantages. But before applying such treatment we must ascertain the state of the cardiac fiber, its intrinsic resources, and its means of nutrition, and we must postpone gymnastic exercises until by [illegible] and by tentative cardiac tonics we have lightened the abnormal burdens of the heart and [illegible] the arterial and venous pressures as well as possible. After such preliminary treatment in cases in which the heart is more overladen than unsound, graduated ascents in Oertel's method may be practised. In more serious cases "resistance cures" by skilled operators are [illegible] but [illegible] not be practised in [illegible].

Cardiac Dilatation and Hypertrophy.—Richard Caton [illegible] cardiac [illegible] to be rapidly [illegible] with cardiac [illegible]. A careful diet [illegible] of [illegible] and [illegible]. When the patient [illegible] enough, graduated [illegible]. The Oertel method [illegible] is laden with fat, [illegible] the warm baths [illegible] cardiac [illegible] of the treatment [illegible] the patient [illegible] must be [illegible] that the [illegible] a [illegible] with his heart and [illegible].

Dilated Hearts as Treated in Recent Times.—A. L. Satterthwaite [illegible] that hypertrophy and dilatation are [illegible] in the [illegible] treatment. Athletic hypertrophy may be [illegible] dilatation of the left heart. Moreover [illegible] than formerly do we realize the rôle of lesions of the nervous system in the pathogenesis of these forms of heart disease. The author gives detailed directions for examination of the patient, and for treatment of the various causes of the condition. Where a lesion of the nervous mechanism plays an important part, treatment by change of climate, baths, and exercise are to be [illegible]. A [illegible] change has been effected in the treatment of these cases, whether rheumatic or otherwise in origin. The policy of [illegible] has given way to the policy of training. Great [illegible] is however necessary. In cases with perturbations of rhythm, digitalis does little good; a course of alkaline bicarbonates, with in [illegible] phenacetin, antipyrin, or occasional hypodermic injections of morphine is better where there is hypertrophy or dilatation of the left ventricle with arteriosclerosis or atheroma; arterial relaxants should be given, and good nutrition must be maintained. Digitalis and iron are not to be given [illegible] and careful [illegible] often produce good results.

The Treatment of Cardiac Dilatation and Asthenia.—[illegible] considers that the following three causes have of late years given rise to the prevailing tendency to cardiac asthenia and dilatation: (1) The influenza epidemic; (2) A [illegible]; (3) Excessive use of tobacco. Sufficient stress has not been laid on the necessity of a prolonged period of physical rest during the convalescence from influenza. This is the [illegible] of all cardiac tonics and [illegible] when cardiac dilatation [illegible] combined with good air and [illegible] food, the most [illegible] remedy. "Resisted exercises" are merely [illegible] in many such cases, but [illegible] exercise [illegible] exercise is [illegible] value. Baths are of some value in chronic cases of cardiac dilatation than are resisted exercises. The Nauheim treatment gives the best results in cases of chronic cardiac asthenia following upon acute disease. It is useful in carefully selected cases of valvular disease, the change from the worries of professional life [illegible] wholesome dulness and quiet of Nauheim constituting a real rest treatment. In addition to open air life, gentle exercise, a light nourishing diet, free action of the bowels, and early hours for retirement, a cardiac tonic is advisable, this consisting usually of strophanthus or strychnine or nux vomica, with coca in combination with iron, quinine, or arsenic. Digitalis should be kept for cases in which there is much dyspnœa and troublesome palpitation.

The Treatment of Colds.—Coryza, if taken in hand at its commencement, is almost always amenable to treatment, but if neglected in the first instance, will cause much trouble.

Some physicians recommend that the most effective way to abort a cold is to go to bed, drink hot lemonade, eat plenty of nourishing food, and stay in bed for twenty-four hours.

A hot bath before retiring to rest is another remedy recommended, and in numerous cases has a beneficial result.

Surgical Suggestions.

Treatment of Accidents Under Chloroform.—It would appear that sudden failure of the circulation, accompanied by pallor of the face and accelerated or gasping respirations, denotes vasomotor paralysis, and requires inversion of the patient with pressure on the abdomen. On the other hand, if the dangerous symptoms are preceded by struggling, and the face is diffused, with signs of venous engorgement, the patient should be alternately raised to nearly the vertical position, in order to empty the heart, and then returned to the horizontal position. Artificial respiration should be systematically persevered in in each case. If there is actual failure of the circulation, little that is useful can be done by efforts to raise the blood pressure by such means as transfusion, etc.

In failure of respiration or circulation, hypodermic injections of strychnine and the extract of suprarenal capsule with inhalation of ether are probably the most useful measures.—*The Medical Press and Circular.*

Carcinoma of the Tongue.—W. H. Chambers (Columbus *Medical Journal*, September, 1901) concludes: 1. Sufficient experience has been accumulated to show that the removal of the tongue in lingual carcinoma prolongs life and adds to the comfort of the patient, and, further, renders a reasonable hope of a permanent cure. 2. All operations should be preceded by an effort to secure thorough disinfection of the mouth and teeth. 3. In the treatment of continued ulcers and sores on the tongue, caustics are to be avoided and all sources of irritation removed. 4. Persistent sores on the tongue should be freely removed by the knife or scissors, if they resist treatment. 5. When the disease is confined to the tongue, Whitehead's operation should be employed for its removal. 6. In this operation the advantage of primary ligation of the lingual artery is not definitely settled, but the weight of authority is against its necessity. 7. The advantage of having one-half the tongue in unilateral disease must be considered undetermined, but the weight of positive experience is in its favor. In splitting the tongue into lateral halves, Baker's method of tearing through the raphe should be employed. 8. A preliminary tracheotomy adds an unnecessary element of danger in the removal of the tongue in ordinary cases. 9. When the floor of the mouth has become involved or the glands enlarged, Kocher's operation should be performed, omitting the preliminary tracheotomy. 10. Removal of the glands by a separate incision after the removal of the tongue must be considered insufficient. 11. Volkmann's method still rests on individual experience. Its just value cannot be determined until it has been subjected to trial by a number of surgeons. 12. Thorough and complete removal should be the aim of all operations, whether for limited or extensive involvement. 13. By whatever method the tongue is removed, the patient should be up and out of bed at the earliest possible moment and should be generously fed.

Gonorrheal Arthritis is commonest in the knee; the ankle and hip are also frequently attacked, while almost any joint in the body may be attacked. It does not occur at any fixed period in the disease, but it is most usually met with between the third and sixth weeks.

Acute Synovitis is one of the commonest affections of the knee and generally occurs after sprains; it is sometimes a result of simple exposure. It may also be associated with rheumatism, although the true rheumatic inflammation of joints affects the fibrous capsule rather than the synovial membrane.

Wounds of Joints, unless they can be kept aseptic are among the most serious injuries we are called on to treat; suppuration in a healthy joint not only leads to complete disorganization of the articulation itself, but also involves a very considerable risk of septicæmia and pyæmia.—*Cheyne and Burghard.*

Volunteer Surgical Assistants.—If you can possibly help it, never allow relatives or other outsiders to be present at an operation. They are in the way, are apt to touch instruments and dressings, and occasionally vary the monotony of the proceedings by fainting at most inconvenient times. If you are compelled to employ their assistance, you will commonly find that the women of the family make better assistants than the men.—*Lilienthal.*

Synovitis of Shoulder.—Acute and chronic synovitis with effusion are comparatively rare in the shoulders, and the condition may be readily overlooked if the distention of the capsule be only slight; when it is considerable, the swelling is most marked beneath the interior ridge of the deltoid, and the upper arm is slightly abducted and somewhat internally rotated.—*Kansas City Index*, October, 1901.

Traumatic Dislocation of the Knee-Joint is a very rare occurrence, as may easily be understood from a consideration of the size of the joint and the strength of the ligaments concerned. Very severe violence is required to produce dislocation, and hence these injuries are usually complex ones, being either compound or complicated, with fracture of the bones in the immediate neighborhood.—*Cheyne and Burghard.*

Perineal Prostatectomy.—A median perineal cystotomy is done, and the finger introduced into the bladder to examine the prostate from its vesical aspect. An incision is next made, commencing at the posterior angle of the cystotomy incision, carried straight back along the median perineal raphe, around the anus, to terminate in front of the coccyx. The left forefinger is then introduced into the bladder, and presses the prostate into the perineal wound. The capsule is incised, and the prostate either shelled out from its capsule or removed piecemeal by cutting forceps and scissors, the method of enucleation depending upon the fibrous or adenomatous condition of the gland. A full-sized drainage tube is then passed through the cystotomy wound and secured in position.—*P. J. Freyer.*

Urethral Calculus is best removed by cutting directly down upon it, especially in boys.

Danger Signs in chloroform narcosis are sudden lividity or pallor, dilatation of pupils, shallow respiration, rapid and irregular pulse, or total absence of radial beat.

In Traumatic Lumbago massage and prolonged baths are strongly indicated. Ordinary baths are just about as useful as alkaline or sulphurous baths, but the latter may have a psychic influence. When there is much effusion of blood, it is best to avoid the use of wet cupping or leeches. Compresses soaked in the following solution are often beneficial:

R	Chloride of ammonium	20 gm.
	Tinture of arnica	10 gm.
	Water	800 gm.

—*Plicque.*

Medullary Cocainization has resulted in two more deaths in Paris, and Broca says the method is not safe in the hands of every one.—*Therapeutic Gazette*, October 15.

Pyloroplasty is the operation of selection for simple pyloric stricture, and gastrojejunostomy should be reserved for cases in which the pylorus is so bound down or involved in adhesions as to be inaccessible.—*Rutherford Morison.*

Empyæma.—Chloroform is the anæsthetic of preference. Deep narcosis is contraindicated, owing to the danger of pus being drawn into the other lung from a ruptured bronchus. In adults resect two inches of the seventh and eighth or eighth and ninth ribs in the posterior axillary line. In children, the seventh, as soon as the diagnosis is made. Simple incision is rarely advisable.—*J. A. Hartwell.*

Book Reviews.

DISEASES OF THE INTESTINES: THEIR SPECIAL PATHOLOGY, DIAGNOSIS AND TREATMENT. By JOHN C. HEMMETER, M.D., Ph.D. In two volumes. Volume I. Philadelphia: P. Blakiston's Son & Co., 1901.

UNTIL very recently there was no special work devoted to the diseases of the intestines. This want has been filled within the last few years, first by the book of [illegible], and then by Bond's translation of Boas, and now by the present work of Hemmeter. The earlier authors had certainly given a very sufficient and careful review of all up-to-date knowledge with regard to intestinal disorders. Hemmeter [illegible] of the much needed [illegible]. Referring to laxatives, Hemmeter expresses himself as follows: "Laxatives should be used not as a prescribed [illegible] routine, but according to special indications. For instance, in atonic constipation, the [illegible] and [illegible] of the intestinal musculature [illegible] be a better purgative than any other in the pharmacopœia. It cannot be emphasized [illegible] that a purgative is the last thing for most forms of constipation. Figs, apples, prunes, fresh rhubarb [illegible] and tomatoes are safe laxatives in their way [illegible]. Substances which simply cause a more frequent [illegible] but still well formed evacuation are called laxatives. Of these, the best and safest is castor oil, then cascara and tamarinds. A mixture of sulphur and cream of tartar mixed up with syrup of oranges and tragacanth is a harmless laxative. Similarly, compound licorice powder."

As there is still a great deal of controversy as to the use of opium in appendicitis and intestinal obstruction, it will be of interest to quote Hemmeter's views on this subject. He says: "There are some medical men, especially surgeons, who argue that opium in any dose or form, given in these conditions, is bad practice, because, in the first place, it obscures the signs and symptoms so that the diagnosis cannot be made; and, in the second place, it produces a state of pseudo-euphoria (or false improvement), which prejudices the patient against an operation that may be necessary. Against the first objection may be urged that morphine or opium may be given in such doses that they do not obtund the sensations entirely or to produce somnolence. Pain must be relieved. This demand is often so imperative that refusal to comply with it frequently causes a dismissal of the physician; and as the keen edge of the pain can always be dulled by one-sixth of a grain of morphine without destroying the chances of a diagnosis, I recommend that it should be given in all cases of appendicitis where there is much pain. There are other clinicians who go further than this and speak of an opium treatment of appendicitis, giving from 20 to 30 drops of the tincture of opium three or four times a day. This treatment has never gained my confidence. I have seen it carried out by other practitioners, but was disposed against it by the remarkable depression which resulted in a number of cases. The second objection, that of the false improvement which might prejudice the patient against an operation, is invalid on the face of it. While it is the duty of the physician to relieve pain, it cannot be considered his duty to withhold a means of relief in order to force upon the patient the conviction of the necessity of an operation. In occlusions opium is indicated in the first periods of reaction. Its administration should be controlled by observing the pulse and general condition of the patient."

As a whole, Hemmeter's book will be read with great interest by the physicians at large, and will certainly prove of great benefit to them.

AN INTRODUCTION TO THE BACTERIOLOGICAL EXAMINATION OF WATER. By W. H. HORROCKS, M.B., Sc. Lond., Assistant Professor of Military Hygiene in the Army Medical School, Netley; Assistant Examiner in Hygiene under the Board of Education, South Kensington; Major Royal Army Medical Corps. Octavo, 300 pages. Philadelphia: P. Blakiston's Son & Co., 1901.

THIS book is just what it pretends to be, an introduction to the examination of water by bacteriological methods. The author assumes a knowledge of elementary bacteriology by the reader, but goes into considerable detail concerning the questions arising when bacteriological methods are applied to the examination of water. After a brief preface, Chapter I gives careful directions for the collection of samples under various conditions. This is followed by a chapter on the estimation of the number of bacteria in definite quantities of water. The third chapter deals with the multiplication of bacteria in water and the influence of various physical and chemical conditions upon their number. The bacterial content of snow, ice, hail, and rain, and of water from rivers, lakes, springs, etc., is next considered, with a chapter on sand-filtration. The author then passes to the qualitative examination of water, devoting more than three quarters of the book to the species of bacteria occurring in water. These are divided into three groups: (1) Those usually found in pure waters; (2) Those common in sewage, but rarely found in pure waters; (3) Those which are the specific causes of disease in human beings, and have been isolated from water supplies. The descriptions of species are good, but the classification is not likely to be particularly helpful to the practical worker who seeks to identify a given species which he has isolated. To give a scheme which could be systematically followed with the successive exclusion of group after group, until the possibilities were narrowed to a few species, among which the nature might be determined, would be a great aid. Such a scheme would be a very substantial contribution to bacteriology. The question of variation in the physiological characters of species is judiciously treated in a manner likely to be helpful to those struggling with the problems of identification. The last two chapters are devoted to a consideration of the mode of action and utility of the Pasteur-Chamberland and Berkefeld filters, a summary, and brief directions for the preparation of culture media.

The value of anaerobic methods of cultivation in the bacteriological examination of water is not considered, although likely to be helpful in the detection of pollution, but this and a few other omissions that might have been avoided with but slight increase in the size of the book are not likely to be important to those who seek an introduction to this particular division of applied bacteriology. To such the book can be confidently commended.

STUDIES IN HETEROGENESIS. By H. CHARLTON BASTIAN, M.A., M.D., F.R.S., Emeritus Professor of the Principles and Practice of Medicine and of Clinical Medicine in University College, London; Consulting Physician to University College Hospital, and Senior Physician to the National Hospital for the Paralysed and Epileptic. First Part. With 210 illustrations from photomicrographs. 71 pages. London and Oxford: Williams & Norgate, 1901.

THE author's thesis is the production of various forms of protozoa from the cells of entirely different species serving as "matrices," and of either vegetable or animal nature. His observations were made upon organisms found in fresh water, kept under conditions which were usually unfavorable for the normal development of the organisms. Among these observations were: "Transformation of the Endochrome of Large Confervoid Cells into Amœbæ" (p. 3), "Transformation of the substance of Euglenæ into Flagellate Monads" (p. 13), etc. From these studies, the author endeavors to reach some explanations of wide-reaching significance, e.g., "Explanation of the existence of lowest organisms at the present day" (p. 11), a problem which he regards as perplexing to the evolutionists. The candid reader can hardly escape a feeling that the author has failed to prove his case. The photomicrographs do not carry conviction; there are no studies of the fate of the "amœbæ" and other bodies formed within the cells observed. How is one to exclude the possibility that these bodies are not gametes belonging in the normal life cycle of the original organism? This conception of their nature is not even considered. We imagine that in studies of this sort it would be of the utmost importance not to trust to morphological characters in the determination of results, but carefully to follow the subsequent phenomena manifested by the bodies being investigated. Shape, size, motility, flagellation, do not alone reveal the nature of an organism of microscopical dimensions. One cannot controvert the generally accepted views of biologists upon such simple inferences as are contained in this work. More evidence is required and must be furnished before serious attention can be claimed for the conclusions so confidently set forth by the author.

A TEXTBOOK OF MEDICINE. Begun by the late CHARLES HILTON FAGGE, M.D., F.R.C.P., sometime Physician to Guy's Hospital. Completed after his death and since revised or rewritten by PHILIP HENRY PYE-SMITH, M.D., F.R.S., Fellow of the Royal College of Physicians, Consulting Physician to Guy's Hospital. Fourth edition, in two volumes. Vol. I, 1,123 pages. Philadelphia: P. Blakiston's Son & Co., 1901.

IN this edition quite a number of alterations have been made, notably a general and more practical rearrangement of the material and the omission of old or abandoned ideas together with such additions as recent medical progress has necessitated. The junior editor is practically responsible for the contents throughout, since, in the four editions which have appeared, most of the original text has gradually been changed. The work is more extensive than the majority of the two-volume textbooks, being closely printed and containing in small type the less important details and references to records of cases. A very valuable feature of the work consists in the fact that the knowledge is generally at first hand and represents the author's vast clinical experience with but little reliance on the opinion of others. The description of diseases is unusually graphic, being embellished by frequent references to necropsy and clinical records. Like most of the recent English books, the author has omitted to describe the recent yellow-fever experiments; but this can hardly be placed in the balance against the unusual excellence and completeness of the work. The publishers expect to have the second and final volume issued before the end of the year.

Transactions of the Clinical Society of London. Vol. XXXIV. 270 pages. London: Longmans, Green & Co., 1901.

This issue of the transactions maintains the high standard set by its predecessors and proves most interesting reading. Nearly fifty cases are reported, the vast majority of which depict some unusual phase of disease, while many are rendered exceptionally instructive by the incorporated illustrations, consisting of excellent radiographs and some colored plates.

The main article is that by Dr. Howard Tooth, on "Typhoid Fever Among the Troops in South Africa," with a full report of the discussions following. It is a valuable compilation.

Practical Medicine. By F. Mortimer Lawrence, A.M., M.D., Assistant in Practice of Medicine, Hahnemann Medical College; Chief of Medical Clinic, Hahnemann Hospital Dispensary. Philadelphia: Boericke & Tafel, 1901.

The author claims for this volume its adaptation only to students and not to advanced workers. It gives, in a well-ordered and condensed manner, all the main facts connected with the more common diseases, and lays special stress on pathognomonic symptoms and diagnostic laboratory procedures. In introducing each section on the special systems, the main questions to be asked of patients are given as useful hints to the beginner. The treatment includes most of the well-recognized procedures of both schools of medicine.

Studies of the Internal Anatomy of the Face. By M. H. Cryer, M.D., D.D.S., Professor of Oral Surgery, Department of Dentistry, University of Pennsylvania. 176 pages. The S. S. White Dental Mfg. Co., 1901.

This manual is a study mainly from a dentist's point of view of the upper and lower jaws, the various accessory sinuses of the nose, effects of pathological conditions in the region of the hiatus semilunaris, impacted teeth, modifications of the normal shape of the bones through abnormal forces, influence of muscular action and hypertrophy of the gums and alveolar processes. It is not a compilation, but represents the results of a careful study by the author of hundreds of skulls. The typal bone is ideal, as studied in the regions under consideration. The actual is a variant, and it is with the latter that the surgeon and dentist have to do. While nothing essentially new is presented, the book shows evidence of the most conscientious study.

A Treatise on Surgery. By American Authors. Edited by Roswell Park, A.M., M.D., Professor of Principles and Practice of Surgery, Medical Department University of Buffalo, N. Y. Third Edition. Philadelphia and New York: Lea Brothers & Co. 8vo, pp. .408.

The third edition of this, now standard, work, while having undergone a thorough revision, is very much increased in size. Excellent as the book is in other respects, it is now altogether too large and unwieldy for the students' use. As a work for ready reference for the general practitioner, it would be much better if it were divided into two volumes and more securely bound. The notable and especially valuable additions to the new edition are those of blood examinations as applied to surgery by Dr. Irving P. Lyon, and the study of tumors by Dr. Harvey R. Gaylord, whose recent investigations along the lines indicated have attracted such wide attention in the scientific world.

A Manual of Bacteriology. By Herbert U. Williams, M.D., Professor of Pathology and Bacteriology, Medical Department, University of Buffalo. 266 pages. Philadelphia: P. Blakiston's Son & Co., 1901.

This little manual is designed to give the beginner in bacteriology an outline of the technical procedures in common use in the study of bacteria, and to furnish the medical practitioner with a summary of the facts concerning bacteria which are likely to be of most importance to him. A brief introduction gives some idea of the general nature of bacteria and their place in nature. Part I deals with elementary technique. Part II treats of classification, physiological character distribution, the relations of bacteria to disease, disinfection, antiseptics, etc. Part III contains a very short summary of the chief characteristics of thirty-one species of non-pathogenic bacteria and a mere mention of yeasts and molds. Part IV consists of seventy-eight pages devoted to pathogenic species.

The book will undoubtedly be useful to those whose duty it is to know something about bacteria. The reader who desires guidance concerning the relative value of methods or aid in forming a critical judgment of the results of bacteriological research will find little help. Perhaps this is hardly to be expected in a work particularly calculated to be of assistance in a practical laboratory course.

A Textbook of Surgery. By Dr. Hermann Tillmann, Professor in the University of Leipsic. Translated from the seventh German edition by Benjamin T. Tilton, M.D., etc., and John Rogers, M.D., etc. Edited by Lewis A. Stimson, M.D., etc. Vol. I.—The Principles of Surgery and Surgical Pathology, with 516 Illustrations. New York: D. Appleton & Co., 1901.

Tillmann's work is one of the most important of the German textbooks on surgery, and is the most satisfactory with which we are familiar. The German editions have followed each other so rapidly that the translators have thought it necessary to issue another American from the last German edition. The present volume covers that part of the subject which includes general surgery, and the pathology of surgical conditions, which are discussed most satisfactorily and comprehensively. As heretofore, the book is paragraphed and arranged with the needs of the student chiefly in mind, but it will nevertheless be found a very useful work of reference to keep on the library shelf. It is hardly necessary to select separate chapters for criticism, but those on infectious diseases, and on diseases and injuries of bones, will be found specially commendable. This edition has been improved by the suppression of some obsolete material, both text and illustrations, and, as a rule, the retained illustrations serve their purpose very well. The work of the translator is, as a rule, good, and the making of the book is excellent. It will, no doubt, continue to be very popular with the student and instructor.

Traité de Médecine et de Thérapeutique. Par P. Brouardel, Membre de l'Institut, Doyen de la Faculté de Médecine de Paris, et A. Gilbert, Professeur agrégé à la Faculté de Médecine de Paris, Médecin des Hôpitaux. Tome VIII: Maladies des Plèvres et du Médiastin.—Maladies de l'Axe Cérébro-spinal. 848 pages, avec 93 figures. Paris: J.-B. Baillière et Fils, 19 rue Hautefeuille.

A list of well-known names indicated how wisely the editor has chosen his contributors, and the evident care in their presentation of the questions assigned to them in this volume serves to keep up the high aim made evident by the early volumes of the series.

Diseases of the respiratory system are completed in this issue, and those of the nervous system begun. Professor Landouzy presents a deep study of pleurisy in its varied phases; Labbé treats of hydrothorax, and Galliard of pneumothorax. The diseases of the cerebrospinal axis are taken up first in the second portion, and Klippel brings the subject to an end with articles on cerebral syphilis, cerebral tumors, and cerebral abscess.

The scope and quality of the labor here presented compares well with that of the seven volumes already reviewed in these columns.

Taschenbuch der Untersuchungsmethoden und Therapie für Dermatologen und Urologen. Second edition. By Dr. Albrecht Freiherr von Notthafft, Privatdozent an der Universität München. Munich: Seitz & Schauer, 1901.

Those familiar with the first edition of this little volume have undoubtedly been aided by the many brief suggestions as to therapy and diagnosis in the realms of cutaneous medicine and uro-sexual disorders.

Many improvements and additions are noted. The print is small, so that there is incorporated in less than 250 pages a mass of information bearing upon nutrition, dietetics, anatomy, physiology, prescribing, pharmaceutics, materia medica, special treatment, examinations of patients, secretions, and deposits, electrotherapy, and medicated baths. German-reading specialists and general practitioners will find in this a helpful little book.

An excellent idea and useful feature of the work is the addition of an international directory of reputable specialists in these branches in all large cities. The accuracy of the whole can be well argued from the few errors which have occurred in the New York list, the most important of which is making "Dr. J. Blake White, Professor for Dermatology on the University Harvard."

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, held January [illegible], 1902.

JOHN B. WALKER, M.D., Chairman.

Oophorectomy for Inoperable Cancer of the Breast.—Dr Franz Torek read a paper on this subject, and presented a patient illustrating this method of treatment. He said that when she was first examined, there was enlargement of the axillary lymph nodes, and as this very considerable enlargement had now disappeared, he inferred that the operation of oophorectomy had the power of exerting some influence even at a distance from the mammary gland. However, the farther away from the gland the less was the effect of this operation. Although cachexia had been very marked on first coming under observation, her general condition had improved very greatly, so that now there was little apparent cachexia. Another interesting feature of the case was that at the time of the operation he had observed what appeared to be carcinomatous nodules of the peritoneum. Dr Torek also referred to a case of recurrent ulcerating carcinoma of the breast upon which he had done oophorectomy. Shortly after the operation there had been a distinct reduction in the size of the enlarged lymph nodes. The improvement had, however, been only temporary, and she had died of a carcinomatous involvement of the pleura.

Remarkable Result from the Toxin Treatment of a Spindle-Cell Sarcoma.—Dr WILLIAM B. COLEY presented a veterinary surgeon, whose home was in Minnesota. He was forty years old, and suffered from a spindle-cell sarcoma on the right superior maxilla. This growth had developed shortly after a severe blow in that region received from a steer. Dr Wheaton of St. Paul had performed a resection of a portion of the superior maxilla, but was unable to remove all of the tumor. The operation had been done on May 7, 1901, and had been a very severe one. The man did very badly after it, and his weight was reduced from 155 to 103 pounds, and the swelling of the part was rapidly increasing. The liver had been enlarged for some time, and he was distinctly jaundiced. The man himself insisted upon being treated by the toxins of erysipelas and the bacillus prodigiosus. At that time his condition was so bad that it was thought he would soon die, and after a few injections had been given, his family physician was strongly averse to continuing them. However, the patient insisted upon having this treatment, and it was continued, with the result that the patient practically recovered in a very short time, and resumed his occupation. His weight had increased from 113 to 142 pounds. With the exception of the first few injections, which were given in the tumor, they were all made into the abdominal wall—a fact of unusual importance as showing the systemic effect of the toxins. The speaker said that in almost all of his own cases the toxins had not been injected at a remote point from the growth, and the result in this case was most remarkable. From the description given him, the man's condition was such that if he had seen him personally he would probably have advised against treatment with the toxins. The original tumor was examined by Dr Haggard, the State microscopist of Minnesota.

Operation for Intraperitoneal Rupture of the Bladder.—Dr JAMES PEDERSEN presented a man of forty years, who, last October, while intoxicated, had fallen out of a window, a distance of about twelve feet. Dr Pedersen had operated about nine hours after the accident through a suprapubic opening, and had found a transverse rent in the summit of the bladder, between two and one-half and three inches in diameter. It was closed by continuous suture of sixteen-day chromic catgut, and the rest of the wound by layer sutures. An opening was made into the membranous urethra.

Removal of Malar Bone for Epithelioma of Cheek.—Dr CHARLES H. PECK presented a woman of thirty-three years, who had come to him last January with an ulcer of the face. Two years and a half before she had first noticed a small nodule on the cheek, and in May, 1898, the nodule had been removed and the wound grafted with skin. Six months later an ulcer had appeared at the site of the operation. When first seen the ulcer was about one inch in diameter, and extended down to the malar bone. A wide excision was performed, and the anterior portion of the zygoma and the entire body of the malar bone were removed and the wound grafted with skin. The chief feature of interest was the age of the patient. This operation was done one year ago. The pathologist reported that the epithelioma was of a malignant type.

Removal of the Whole Omentum for Intra-Abdominal Torsion.—Dr J. WIENER, JR., presented a young man who had been sick three days before coming under observation with symptoms pointing to appendicitis. His pulse was [illegible], and the temperature 101° F. The patient was admitted to the service of Dr Lilienthal with the diagnosis of appendicitis. On examination, a mass was to be felt in the upper right quadrant of the abdomen, and his only diagnosis before opening the abdomen was peritonitis in the region mentioned. He was operated upon the day after admission, a small exploratory incision being made first. This revealed a deeply congested omentum, and led him to make a diagnosis of torsion of the omentum. The incision was then increased until eight inches in length. There was a little bloody fluid in the general peritoneal cavity. The omentum was almost black, and was very freely adherent in the right half of the abdomen. After freeing the adhesions, the pedicle of the omentum was found to be situated about one inch from the transverse colon. The entire omentum was affected by the torsion. There were two twists from left to right, and a twist in the opposite direction. The pedicle was ligated, the whole tumor removed, and the wound closed without drainage. The patient left the hospital four weeks afterward. A very interesting feature of the specimen was an enormous dilatation of the lymphatics. Dr Wiener said that about one year ago he had presented to this section a case of omental torsion, which he had diagnosticated as appendicitis. There had been only six cases of omental torsion placed on record up to 1900.

Radical Cure of Hydrocele.—Dr A. A. BERG presented a man to illustrate the result of operation for the radical cure of hydrocele. The operation had been done one year ago. The speaker said that he had performed this operation twice for hydrocele and twice for hernia. The technique was described by means of a diagram, and the comment made that when the peritoneal prolongation was very thin and brittle, as was often the case in infants, this method was particularly valuable.

Dr W. R. PRYOR, speaking of the case presented by Dr Torek, said that the operation of oophorectomy for carcinoma of the breast was based solely on a clinical experience comprising forty-one cases, and had no strictly scientific basis. Roger William had analyzed 12,000 of Sir Spencer Wells' cases, and had found that the removal of the ovaries increased the chances of cancer six times. Of seventeen cases favorably influenced by oophorectomy, twelve had received thyroid extract. Twenty-one cases received no benefit from oophorectomy, and of these only five received the thyroid extract. This in itself was a very significant fact. Thyroid extract was known to improve cancer; indeed, any agent which would markedly disturb metabolism would exert a potent influence on cancer. It was known that oophorectomy would check phthisis, but certainly no one would think of performing oophorectomy for this purpose. He hoped this new treatment would not be followed, as it was founded on an absurd argument, and this operation for an incurable disease carried with it a mortality of 5 per cent.

Dr FRED KAMMERER said that the disappearance of the enlarged glands in the neighborhood of the breast had been cited by Dr. Torek as evidence of the improvement effected, but it seemed to him more than probable that this diminution in the size of the lymph nodes was due to the removal of the ulcerated surface, and that these nodes were not really carcinomatous.

Dr. Coley said that he had followed out quite carefully all of the cases that had been reported as cured by this operation, and had not been convinced that there had been an undoubted cure by this method. Only 6 per cent. of the cases reported as having been treated in this way had been followed more than two years. He recalled having seen a case of carcinoma which Dr. W. T. Bull had declared to be inoperable, and yet the patient lived for seven years afterward.

Dr. Robert T. Morris said that we all recognized the fact that rapid degeneration of the whole sex apparatus followed removal of the ovaries. Further changes, when the ovaries were removed after the menopause, must be put down to the removal of the "internal secretion of the ovaries." We might reason that the rapid degeneration of the mammary glandular tissue made that tissue an unfit culture ground for the protozoa of cancer, assuming for the purpose of argument that cancer was of protozoan origin; but the curious fact was that the mammary-gland tissue had already been removed in cases of recurrent cancer that were thought to be suitable for ovariotomy, and we were dealing with a different set of tissues altogether. It was no argument against the operation of ovariotomy to say that statistics showed that the liability to cancer was increased six times by ovariotomy. The homœopathists might seize upon the fact to show that this was in accordance with their doctrine, if we turned about and did for inoperable carcinoma the thing that favored its development in normal individuals. It was true that different forms of carcinoma run a very different course without interference. It was the pathologist, rather than the surgeon, who should give us the prognosis in these cases to-day. Two of the forms of adenocarcinoma were comparatively benign. We could not toss aside the statistics of beneficial results of ovariotomy in cases of inoperable carcinoma. They came from sources that were too responsible, and hence we should accept the empirical fact and proceed to reason backward. We could not deny certain facts on the ground that they were not in accord with *a priori* deductions. If some inoperable carcinomata distinctly underwent favorable changes after ovariotomy, then some patients should be given that advantage. He had recently operated in two cases, telling the patients that the treatment was largely experimental.

Dr. Torek said that he did not wish to be understood as recommending oophorectomy whenever there was any possibility of doing one of the recognized direct operations. He had approached this subject with even more skepticism than had been evinced by those who had just spoken, but he had been profoundly impressed by the disappearance of a marked cachexia in the cases reported by him. The infiltrations in the axilla were very large and hard, and must have been carcinomatous. He had no explanation to offer concerning their disappearance, but the subject seemed to be sufficiently obscure and of enough importance to warrant surgeons in carefully reporting individual cases.

Dr. Frederick Holme Wiggin, referring to Dr. Pedersen's case, said that he had found no difficulty whatever in securing healing of wounds of the bladder. In one case, already reported, the wound, although three and one-quarter inches long, had healed very kindly after suture and drainage of the bladder. When cystitis was not present, he thought wounds of the bladder healed as readily as wounds of the intestine. He was in the habit of using two rows of stitches and bringing the peritoneum over the line of suture.

Dr. A. A. Berg said that he had recently seen a number of cases of epithelioma that had been subjected to the *x*-ray. All of the cases of flat epithelioma of the skin had done very well under daily applications of the *x*-ray from a low vacuum tube, the latter being applied very closely. In none of the cases had an *x*-ray dermatitis developed. In all the other cases of carcinoma treated in this manner, a number of them being recurrent carcinomata of the breast, it seemed to him that the *x*-ray acted by producing superficial cauterization, and at the same time stimulating the growth in the tissue at the periphery.

Dr. Torek said that, according to his experience, both epithelioma and carcinoma were far more malignant in younger than in older subjects. He could not recall a single case in which he had succeeded in curing a carcinoma of the breast in a woman under thirty years of age. In such persons the recurrence seemed to take place very early.

Dr. Martin W. Ware said that he had found three additional cases of torsion of the omentum reported in an article by Hussey. The mortality in these cases was about 15 per cent. The torsion occurred in persons having hernia. Such cases generally called for a very large and wide incision.

Dr. J. Wiener showed for Dr. H. Lilienthal a specimen of torsion of the omentum, removed from a man who had come into the hospital with symptoms of appendicitis. Hernia, he said, did not always take place in connection with torsion; it was simply a coincidence. This case of Dr. Lilienthal's had no hernia. In at least four of the cases there had been nothing in the hernial sac; in others a portion of the omentum had been found in the sac. In all of the cases that he had collected there had been no mortality, and he did not think there should be any in cases diagnosticated early and promptly subjected to operation.

The Cure of Hydrocele by the Injection of Minute Amounts of Carbolic Acid.—Dr. William B. Coley read a paper on this subject. The carbolic-acid method of treating hydrocele, he said, had been introduced to the profession by Levis, in 1881, and he had used from 30 grains to a drachm and a half of the acid. These patients had not exhibited any evidence of carbolic-acid poisoning, had suffered no pain, and had not been incapacitated from attending to their usual work. Various accidents had followed the use of both iodine and carbolic-acid injections, and some surgeons had gone so far as to advise the open incision method as safer and more satisfactory. From 1891 to 1900, 2,240 cases of hydrocele had been treated at the Hospital for Ruptured and Crippled. Of this number, 1,603 had been in children under fourteen years of age. Nearly all of the hydroceles in infancy either disappeared spontaneously or could be cured by the application of equal parts of tincture of iodine and tincture of belladonna. For hydrocele in the adult, the speaker said he now made use of small injections of carbolic acid. Each injection consisted of two and one-half minims of Schering's carbolic acid, with the smallest quantity of glycerin necessary to liquefy the acid. He had found the results just as good as from the larger injections of this acid, and they were associated with less risk and discomfort. It was of the greatest importance that the solution of carbolic acid should be sufficiently concentrated. A number of the earlier cases had been treated with the ordinary commercial carbolic acid, and the results had not been nearly so good as when the more concentrated acid of Schering had been used. It had been found convenient to make use of a small double trocar. The hydrocele fluid having been very thoroughly evacuated through the outer trocar, the carbolic acid should be injected through the inner trocar attached to a hypodermic syringe. He was certain that the carbolic-acid injection-method was the best yet devised for the cure of hydrocele. He believed the use of this very small amount of carbolic acid was absolutely free from risk, and careful examination of the thirty-six cases so [illegible] showed a very uniform [illegible]. The [illegible] had not been followed and [illegible] been passed by the [illegible] of [illegible] to hydroceles of long standing [illegible] in old persons.

Dr. J. [illegible], Jr., said that he had been accustomed to cure hydroceles by the injection of the ordinary so-called "pure carbolic acid" in quantities of two or three drachms. There had been quite a number of relapses, and it had seemed to him that the injection of the larger quantities was responsible for undue inflammatory reaction.

Dr. Ward said that he had tried the [illegible]-method in about one-third of hydroceles treated during the past six years. He had selected for this treatment cases with a thin tunica, and had been able to follow a fair proportion of them. He could now recall six cases in which there seemed to have been a cure effected. He had made use of the crystallized carbolic acid liquefied by heat, using a trocar and a hypodermic needle.

Dr. A. Ernest Gallant said that he had followed up [illegible] cases of hydrocele that had been treated in dispensary practice with the ordinary injections of carbolic acid. It was almost impossible to inject the carbolic acid and withdraw the cannula without some of the carbolic acid trickling down through the puncture opening. This, he believed, produced an eschar, and made the sac permeable. It was desirable to make free use of vaseline on the scrotum, in order to avoid the unpleasant effects arising from the spilling of the acid. The injections had been followed by a good deal of soreness and considerable pain.

Dr. E. M. Foote said that at the Vanderbilt Clinic he had probably seen several hundred hydroceles treated, and he was sure that many hydroceles would recur after any method, even the open method. He had seen many recurrences even after the injection of carbolic acid. He recalled one case of double hydrocele in which one side had merely been tapped and the other side injected. The man returned some time afterward with a recurrence, but only on the side that had been injected with the acid. It was certainly most important to secure the evacuation of all the hydrocele fluid prior to making the injection.

Dr. [illegible] said that if the double trocar employed by [illegible] were used, there would be no trouble from leakage of the acid. This instrument was most useful in enabling the operator to squeeze out every drop of the hydrocele fluid, and be sure that the carbolic acid was then injected into the sac.

A Stethoscope for Anæsthetists.—Dr. Frederic Griffith presented a simple stethoscope so constructed that it might be kept in position on the patient and in the ears of the anæsthetist during the administration of an anæsthetic, thus leaving free the hands of the anæsthetist.

A Case of Extreme Deafness with Tachycardia.—Douglas Stanley reports the case of a man who had recently recovered from typhoid fever and who was suffering from tachycardia and extreme deafness. Ears and throat were in normal condition. The patient had not been taking any drug of importance, but had been smoking a very strong form of twist, eight to nine ounces per week. He was ordered to give up smoking, and given rhubarb and soda. The treatment was, of course, directed to the tachycardia, and a month later this was greatly improved. To the physician's surprise, the deafness had practically disappeared, and the man, from looking a stupid idiot, turned out to have very fair mental power. The question is, what was the nature of the deafness? The account of how it began, and the normal appearance of the membranes negatived the view that it was a relic of typhoid fever. Its disappearance on withdrawal of the tobacco seemed to support the idea that it was a toxic deafness similar to tobacco amblyopia.—*The Birmingham Medical Review.*

NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

Stated Meeting, Held January 21, 1902.

James N. West, M.D., Chairman pro tem.

Ergot in Graves' Disease.—Dr. R. Van Santvoord read a paper on this subject, in which he called attention to the fact that in all the cases of Graves' disease that he had observed the sphygmographic tracings had shown good amplitude with a rapid falling off after the primary wave with a well-marked dicrotism. It was recognized by medical authorities that the ordinary heart tonics had little effect upon the heart in Graves' disease. A few cases were reported to emphasize the desirability of giving attention to the peripheral circulation in connection with the symptomatic treatment of the disease.

Dr. James K. Crook said that at one time he had used ergot in this disease, but with a somewhat different object in view. If the thyroid gland could be restored to its normal state, the normal action of the heart restored, and the nervous phenomena controlled, one could practically cure the disease. The general opinion at the present time was that Graves' disease was due to an enlargement of the thyroid gland and an excessive formation of thyroid secretion. Experience seemed to show that drugs which possess the power of lessening glandular activity ameliorate the symptoms of Graves' disease. If ergot were capable of diminishing the supply of blood to the thyroid gland it should be of service in this disease, and certain observers had reported observation apparently confirmatory of this view. The speaker said that he had injected ergotin into the thyroid gland once a week for some time in such a case, and thought there had been some diminution in the size of the gland. However, he preferred to make use of belladonna or atropine, or else the phosphate of sodium.

Dr. Van Santvoord said that it had seemed to him in watching the last two cases particularly, the action of the ergot had been very immediate and direct, and had lessened the pulse and added to the patient's comfort. He had given this drug as a symptomatic remedy, and without any idea of effecting a cure.

Loud Bleating Heart Murmur.—Dr. Louis Faugères Bishop presented a colored woman, who, four years ago, following immediately upon a fright, had developed symptoms of cardiac disease. These symptoms had continued up to the present time. On examination, a bleating murmur was audible over the heart, and was so loud that it could be heard by the patient herself and by the physician without placing the ear directly against the chest.

Tenderness at the Ensiform Cartilage as a Sign of Cardiac Incompetency.—Dr. Bishop also presented two cases illustrating this sign. The first patient was a colored woman having myocarditis. At intervals the heart would fail, and at such times the first thing noted was a pain and tenderness below the ensiform cartilage. The other patient was a man with rheumatic valvular disease of the heart. On admission to the hospital there was acute dilatation of the heart, accompanied by decided enlargement of the liver and marked anasarca. This patient also exhibited tenderness at the xiphoid cartilage.

Dr. S. S. Burt said that he had had a similar case to the one with the musical murmur. In his case the murmur could be heard at the distance of two feet, and the patient had sought advice because conscious of this noise himself. It was probable that the stream of blood had been broken up by a band, the latter being set in vibration. The murmur had diminished so that in a few months it could only be heard with the ear on the chest. Singularly enough in this case, the prominent point in the history was also a fright.

Aneurysm of the Ascending Arch of the Aorta with Bovine Heart.—Dr. S. S. Burt presented a man with a greatly enlarged heart. There was a soft double murmur at the apex, which became rough at the base. At the second interspace a decided systolic thrill could be felt. The aorta was dilated, and the heart was dilated and hypertrophied. An x-ray photograph of the heart and aneurysm was exhibited. Both alcoholism and syphilis had been excluded.

Mitral and Tricuspid Insufficiency with Pulsating Liver.—Dr. Burt also presented this case. The man had been tapped and the fluid allowed to escape gradually from the abdomen. In this case a small trocar was used, but he preferred to make use of the aspirating needle. He was compelled to say, however, that although he had removed the ascitic fluid very gradually in this way in many cases, the fluid seemed to reaccumulate as rapidly as it was evacuated.

A Case of Long-standing Mitral Regurgitation.—Dr. James K. Crook presented this historical case. The patient, a journalist, had had an attack of acute articular rheumatism in 1864. The diagnosis of mitral regurgitation was made by Dr. Austin Flint, Sr., in 1865, and the man was under the care of this physician as well as of others of note, such as Dr. George M. Beard and E. Darwin Hudson, all of whom were now dead. The patient had been under Dr. Crook's care since 1890, and had been presented to the New York State Medical Society in 1897. The man had had several subsequent attacks of acute articular rheumatism, but there had been no increase in the cardiac lesions. The chief point of interest in this case was that the mitral regurgitation had lasted for thirty-eight years, and the man was still in the perfect possession of his mental and physical powers.

Dr. J. J. Walsh said that he had seen in Vienna a hale and hearty man of sixty-nine years, who had had mitral regurgitation for forty-six years.

Dr. Burt said that he had long maintained that in many of these cases of mitral regurgitation the prognosis was good, and he believed the life insurance companies were beginning to realize that these heart cases were often good risks.

Loud Musical Diastolic Aortic Murmur.—Dr. Alfred Meyer presented a man of thirty-three years, the father of three healthy children. His family history was negative, and he claimed never to have had rheumatism. He had been accustomed to smoke ten cigarettes daily for fifteen years, and to take four whiskeys a day during most of this time. The symptoms of which he complained had been first noticed three years ago. Auscultation showed a diastolic murmur developed at the aorta, and of a distinctly musical character. In hearing such a murmur, one should attune the ear first by listening with the stethoscope. The murmur could be heard at a distance from two to six inches from the chest, varying with the conditions present at the time. It could be heard down the spinal column as far as the sacrum. There was marked pulsation in the vessels of the neck, a distinct Corrigan pulse, and a very plain capillary pulse, though no centripetal pulse. These distance murmurs were quite rare even in the experience of those who saw a great deal of cardiac disease. Perhaps one such case in 300 of cardiac disease would fairly represent the frequency of these distance murmurs. It was probable that there was an enlargement of the aortic orifice or a dilatation of the root of the aorta, thus involving the cusps of the valve in a relative insufficiency. In order to produce a musical murmur the surface must be quite smooth; rough surfaces did not give them. A few autopsies seemed to support the theory just given regarding the causation of these musical murmurs.

Aortic Musical Murmur and Visible Arterial Pulsation.—Dr. William H. Katzenbach presented a man having an aortic systolic and diastolic musical, though not a distance, murmur. The Corrigan pulse was very marked, the "brachial tap" could be readily elicited, and there were visible pulsations in almost all of the superficial arteries. The history of heart disease dated back many years, and the etiology was supposed to be an attack of syphilis in youth. By the brachial tap was meant a "water-hammer pulse," obtained by applying the fingers lightly to the brachial artery.

Dr. Burt said that Dr. Meyer's case was the first diastolic musical murmur that he had heard. He had listened to a number of musical murmurs audible on placing the ear upon the chest, but to only two musical distance murmurs, and these were both systolic.

Chronic Myocarditis.—Dr. U. F. Martin reported the case of a woman of forty-nine years, in the wards of St. Luke's Hospital, suffering from chronic myocarditis. She was non-alcoholic, and had no specific history. About eighteen months ago, she had been suddenly seized with dyspnœa at night. She had since then suffered considerably from cardiac incompetency, and had made the rounds of the hospitals. The heart was enlarged, and its action was very irregular. The only cause for the myocarditis that was discoverable was a general cirrhosis involving the kidneys and other organs. Such cases were usually greatly improved after a few weeks of treatment, but they were not in a condition to become self-supporting. The case was presented as a text for some timely and practical reflections as to the best way of caring for these persons, without interfering with the work of the hospitals for acute diseases.

Dr. Burt said that there should be a well-endowed hospital for chronic heart disease in this city, just as there should be ample hospital accommodation for consumptives. He hoped that when we got through endowing libraries, something would be done for these poor people. It was well to take care of the head, but he thought it was equally important to look after the heart.

Dr. Meyer commended the remarks of the last speaker, and added that there were already a number of institutions for chronic invalids. The question under discussion was akin to that of the care of the consumptive poor; for it was not enough to have institutions for the sick, but for the families of these invalids.

A Scientific Treatment for Deafness.—M. Marage, says the New York *Sun*, has lately communicated to the Paris Academy of Sciences a scientific treatment for deafness which is substantially as follows:

(1) Measures accurately the auditive sensitiveness by causing the patient to listen, at a constant distance, to the sounds of a siren reproducing the fundamental vibration of the vowel sounds. The intensity of sound being proportional to the pressure of the air, the auditive acuity is — when the pressure must be n millimeters in order that the sound may be heard. The normal acuity, unity, is that of an ear which hears the sound under a pressure of one millimeter.

(2) Make the patient listen to the sounds of the same siren through a tube provided with a membrane which transmits all vibrations without introducing or suppressing any of the harmonics. This is a kind of massage of the ear, made by vibrations, which it is destined normally to perceive. This treatment is never painful, and never produces buzzings or increases the deafness, and has frequently produced excellent results.

India's Animal Hospital.—Europeans and Americans boast much of their kindness to animals, and yet there is a hospital for animals in India which surpasses anything of the kind in the western world.

This hospital is at Sodepur, and was established fourteen years ago, the object of its founders being to provide not only a place in which sick and injured animals could obtain medical and surgical attendance, but also a home in which old animals could pass their remaining days peacefully. Since the hospital was opened, thousands of animals, birds, reptiles, and insects have been cared for in it, among them cows, sheep, horses, donkeys, dogs, cats, monkeys, goats, parrots, pigeons, chickens, elephants, and snakes.—*New York Herald.*

Medical Items.

Contagious Diseases Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending February 1, 1902

	Cases	Deaths
Measles	7[illegible]6	22
Diphtheria and croup	346	51
Scarlet fever	[illegible]	29
Smallpox	42	15
Chickenpox	45	
Tuberculosis	[illegible]79	119
Typhoid fever	13	8
Cerebrospinal meningitis	[illegible]	4

The Social Evil in Cincinnati.—The Cincinnati Board of Health was recently made defendant in a suit brought at the instance of a taxpayer to restrain the Health Officer, Dr. Clark W. Davis, from enforcing a regulation for the medical supervision of prostitution. The petition of the plaintiff stated that the defendants "have adopted and are enforcing a regulation requiring all known prostitutes of said city to submit to a personal examination once every week by the district physicians to determine whether they are affected with any venereal disease, and if found free, that each prostitute receives a certificate containing her personal description, and the recital of the fact that she is free from disease, which certificate can only be obtained from the health office, and must be conspicuously displayed in the room of such prostitute; that these certificates are made out in triplicate, one for exhibition by the person examined, one for the health department, and one for the chief of police; that if any prostitute is found to be affected with venereal or other infectious disease, she is not permitted to remain an inmate of such house of prostitution or assignation, but is sent to the city hospital or branch hospital of the city; and, finally, that said district physicians charge each prostitute the sum of fifty cents for each examination and certificate." The plaintiff averred that such examinations and charges therefore were an abuse of the corporate power of the city of Cincinnati, and prayed for a restraining order. The defense was that it was known to the health officer that in certain houses and localities contagious or infectious diseases prevailed more than elsewhere, and that periodical visits and inspections of such places, together with examinations of those suspected of disease, were made in the interests of public health and to prevent or restrict disease. The suit was dismissed. During the past year Dr. Davis has had regular examinations made of the women of disrepute in Cincinnati, has been prosecuted in almost every court in the city, and has successfully defended the right of the health officer to make examinations for the suppression of this disease. The result of these examinations is shown in a very material decrease in the number of cases of venereal disease in the city.

Philadelphia Pediatric Society.—At a stated meeting held January 14, Dr. J. H. McKee presented "A Case of Asthma Apparently Due to Enlarged Bronchial or Mediastinal Glands," and also "A Case of Specific Dactylitis." Dr. Alexander McAlister read the report of "A Case of Tetany Occurring in a Child in whom, following [illegible] [illegible] previously present became [illegible]. Treatment [illegible] but recovery ensued." Dr. J. Allison Scott presented a child exhibiting general cyanosis with marked clubbing of the ends of the fingers and toes and [illegible] impairment of vision. No abnormal cardiac sound could be heard, and the suggestion was made that the condition consisted in some congenital defect, such as imperfect closure of the interventricular or interauricular septum, or stenosis or occlusion of the pulmonary artery, or the presence of a single ventricle from which both aorta and pulmonary artery arose. Dr. E. E. Graham presented the "Report of a Case of Congenital Heart Disease, with Exhibition of the Specimen; Pathological Report by Dr. [illegible] C. Rosenberger." In this case there was found [illegible] stenosis of the pulmonary artery and a deficiency in the interventricular wall, while the aorta arose from both ventricles. During life examination had failed to disclose evidence of the conditions found, although at the time both respiration and heart-beat were greatly accelerated. Dr. S. McC. Hamill read by invitation a "Review of the Work of the Milk Commission for the Year 1901." Dr. Thompson S. Westcott delivered the "Annual Address of the Retiring President." The following officers were elected for the ensuing year: *President,* Dr. S. McC. Hamill; *Vice-Presidents,* Drs. D. J. Milton Miller, John H. [illegible], Augustus A. [illegible]; *Secretary,* Dr. C. H. Weber; *Treasurer,* Dr. H. B. Carpenter; *Recorder,* Dr. D. L. Edsall.

Vaccination Creed of the Chicago Board of Health.—One method of the Chicago Board of Health in its war against smallpox is the distribution of circulars in all lodging houses, police stations, cheap hotels, waiting rooms, and all places frequented by members of people, especially of the tramp or vagrant class. Attention is called to them by placards 14 × 11 inches in size, which contain the text of a *Vaccination Creed* reported also on the fourth page of the circular. These placards are posted in conspicuous places about the premises, and a note at the bottom informs the reader that "Further information as to vaccination and smallpox is contained in the *Supplement to a Vaccination Creed,* copies obtainable on the premises." The following is the text of the "Vaccination Creed":

We, the undersigned, hereby publicly profess our firm belief—based upon positive knowledge gained through years of personal experience and study of smallpox and vaccination: (1) That true vaccination—repeated until it no longer "takes"—always prevents smallpox. Nothing else does. (2) That true vaccination—that is, vaccination properly done on a clean arm with pure lymph and kept perfectly clean and unbroken afterward—never did and never will make a serious sore. (3) That such a vaccination leaves a characteristic scar, unlike that from any other cause, which is recognizable during life, and is the only conclusive evidence of a successful vaccination. (4) That no untoward results ever follow such vaccination; on the other hand, thousands of lives are annually sacrificed through its neglect—a neglect begotten of want of knowledge. ARTHUR R. REYNOLDS, M.D., Commissioner of Health, City of Chicago. HERMAN SPALDING, M.D., Chief Medical Inspector, Department of Health.

The Norwegian Hospital of Brooklyn has, since 1887, been in receipt of nearly $4,000 annually from an anonymous donor. The amount was paid regularly in quarterly instalments of $[illegible]0, but the Deaconesses in charge of the institution have only just learned whence the gifts came. The amount was the interest at 6 per cent. on $[illegible]4,000, which the late Mr. Alfred Corning Clark left in trust for this purpose, with the express understanding, however, that the donation be made anonymously, and the donor's name be kept a secret until such time as it should be decided to hand over the principal. Mr. F. G. Bourne, who has had charge of the fund, has now made public the giver's name, while handing over the sum to the trustees of the hospital as a permanent trust fund to be known as the "Skougaard-Severini Memorial."

Congress on Tuberculosis.—The third annual session of this congress is announced to be held on the 14th, 15th, and 16th of May, 1902, in this city, in Joint Session with the Medico-Legal Society. There will be two sessions each day, and no evening session, except on the 15th, when the banquet will be given. There will be, aside from all papers of a miscellaneous nature, four symposiums arranged, each to occupy one session of the body: (1) Preventive Legislation, Embracing the Social, Municipal, and State Aspects of Tuberculosis. (2) Tuberculosis in Its Pathological and Bacteriological Aspects. (3) The Medical and Surgical Aspects of Tuberculosis. (4) The Veterinary Aspects of Tuberculosis. The Secretary of the Congress is Mr. Clark Bell of this city.

Mortality in Michigan During December, 1901.—The returns of vital statistics of Michigan show that during the last week of 1901 there were 2,770 deaths returned, corresponding to a death rate of 13.5 per 100,000 population. This number is an increase of 316 over the previous month, but is only 95 more than the number returned for December, 1900. There were 387 deaths of infants under one year of age; 182 deaths of children aged one to four years, both inclusive, and 853 deaths of persons aged sixty-five years and over. The most marked increase of the month was in the mortality of the aged. There were three deaths from smallpox during the month.

War Against Mosquitos in New Jersey.—Professor Smith, New Jersey State Entomologist, announced, at the recent annual meeting of the State Agricultural Society, that he intended to ask the Legislature for an appropriation of $10,000 for the further investigation and possible extermination of the New Jersey mosquito. Certain members, it is expected, will fight the proposed legislation on the ground that the mosquito is beneficial to rheumatic natives. One Assemblyman, who fought valiantly all efforts to legislate against the New Jersey mosquito a few years ago, declared that the bite of the mosquito had proved a sure cure for rheumatism.

The National Health Service.—The following resolution was passed by the American Society of Naturalists and by the Council of the American Association for the Advancement of Science, Chicago, Ill., at meetings held during the last week in December, 1901:

Resolved, That the Council of the American Association for the Advancement of Science approves of the efforts to strengthen the administration and work of the Marine Hospital Service by its establishment as a National Health Service in the direction of promotion of the public health, the furtherance of scientific investigation relating thereto, and the securing of the coöperation of experts in hygiene and related subjects.

Opposition to Camps for the Tuberculous.—A meeting of a number of residents of the townships of Pocono, Paradise, and Coolbaugh, Penn., was held recently at Stroudsburg, to organize a health association for the Pocono region, and to prevent the location of consumptive camps in that region. The residents of the Pocono Mountains, whose interests are largely centered in the hotel and boarding-house business, have been aware for some time that a movement has been initiated for the establishment of sanitariums for consumptives in that region, and they oppose it bitterly.

"Raccolta di Memorie Italiane Sulla Laringologia, Rinologia ed Otologia."—This is the title of a new publication established in Turin under the editorial management of Dr. I. Dionisio. It is to be a collection of medical monographs on subjects in the specialty noted, published at varying intervals. The articles are published in both Italian and French. There are two memoirs in the first fasciculus, the first by Dr. Ignazio Dionisio, on the prevention of obstruction and expulsion of laryngeal tubes; and the other by Dr. Adolfo Casassa, on the results obtained by intubation with laterally perforated tubes.

Smallpox a Crime.—It is reported in the papers that Dr. H. M. Bracken, secretary of the Minnesota State Board of Health, in a public address delivered recently in Minneapolis, declared that everybody of discretionary years found afflicted with smallpox ought first to be cured and then sent to jail for ninety days. Dr. Bracken explained that thorough demonstration had been given of the preventive value of vaccination, and there was no excuse for smallpox in civilized countries.

Filthy Lucre.—The Ohio State and local boards of health, before ending their annual session, held recently in Columbus, adopted a resolution declaring against the continued use of paper money after it has become soiled from constant handling. Dr. Thomas Clarke of Massillon said that the paper currency of the country, after it has been in use long enough to become dirty, is one of the prolific sources of disease, and one of the most dangerous carriers of bacilli in existence.

The South African Reconcentrado Camps.—A blue book recently presented to Parliament shows an improvement in the conditions in the Boer concentration camps over those that prevailed some months ago. The report states that in the month of December there were 117,017 whites in the concentration camps in South Africa. The total number of deaths in the month was 2,380, being an annual death rate per 1,000 of 244 compared with 285 for the month of November.

A Woman House Surgeon.—A woman was appointed by the committee house surgeon to the Macclesfield Infirmary some time ago, and now refuses to resign, although the entire honorary staff object to a female in that position. She pretends she is contending for a principle, but it seems to be going rather far for a woman doctor, however competent and wedded to science, to force her attendance on males, especially on patients with genito-urinary diseases.

Mortality of Alpine Climbing.—A report in the *Sun* states that statistics just published in regard to the number of accidents in the Swiss Alps during the past year show that 119 lives were lost. This breaks the record, and is twice as large as the fatalities in 1900. Chamounix, which has been the principal death center since the first ascent of the Matterhorn in 1850, was responsible for the loss of thirty lives.

Philadelphia Academy of Surgery.—At the annual meeting held January 6, the following officers were elected for the ensuing year: *President*, Dr. Richard H. Harte; *Vice-Presidents*, Drs. Henry R. Wharton and John B. Deaver; *Secretary*, Dr. William J. Taylor; *Treasurer*, Dr. William G. Porter; *Recorder*, Dr. John H. Gibbon; *Council*, Drs. Robert G. Le Conte and W. Joseph Hearn; *Business Committee*, Drs. J. H. Jopson and G. G. Davis.

Homesickness in the Philippines.—It is said by medical men in Manila that a considerable amount of the breaking down in health among American residents of the Philippine Islands is due to their nostalgia. The newspapers of Manila are urging the Philippine Commission to make an appropriation for a daily cable-news service from the United States, thus bringing Americans there into closer touch with their home life.

Philadelphia County Medical Society.—At the stated business meeting held January 15, the following officers were elected for the ensuing year: *President*, Dr. Thomas H. Fenton; *First Vice-President*, Dr. Francis M. Perkins; *Second Vice-President*, Dr. J. Chalmers Da Costa; *Secretary*, Dr. Ellwood R. Kirby; *Treasurer*, Dr. Collier L. Bower; *Assistant Secretary*, Dr. William S. Wray.

Drug and Food Adulteration.—According to a report presented at the recent annual meeting of the Drug Trade Section of the New York Board of Trade and Transportation, extensive adulteration of the essential oils used in the manufacture of confectionery is being practised in this city. The section decided to take steps to stop this practice.

Jefferson College Alumni.—An attempt is being made to secure the names and present addresses of the living officers of each class graduated from the Jefferson Medical College since its foundation, and the alumni are therefore requested to send such information concerning the officers of their respective classes at the Jefferson Medical College, Philadelphia.

A Sanatorium for Consumptives in Colorado.—General William J. Palmer has announced his intention of giving [illegible] acres of land and $[illegible] to establish a semi-philanthropic sanatorium in Colorado Springs for consumptives, the institution to cost in all $[illegible]. The remainder of the money is to be raised by subscription.

The New "Journal of Obstetrics and Gynecology of the British Empire" appeared on January 1, with Mr. Alban Doran as editor-in-chief. His colleagues are scattered through the empire. The list is so lengthy, they can only be regarded as contributors, or if otherwise, Mr. Doran's task of driving is not to be envied.

Habitual Drunkards in Lauben.—The names of habitual drunkards in Lauben, Silesia, are printed, and a list is given to each saloonkeeper. Any person supplying one of them with intoxicants is subject to a heavy fine.

Dr. **Seymour Oppenheimer** has been appointed Laryngologist and Otologist to Gouverneur Hospital, New York City.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended February 1, 1902:

TUMORS OF THE CENTRAL NERVOUS SYSTEM—REMARKS ON NOTEWORTHY CASES.

By JOSEPH COLLINS M D
NEW YORK.

PRESIDENT OF THE NEW YORK NEUROLOGICAL SOCIETY AND OF THE AMERICAN NEUROLOGICAL ASSOCIATION.

I.—**Brain Tumors.**—Tumors of the central nervous system are of such frequent occurrence, and their diagnosis is usually so readily made, that it is within the experience of every practitioner to have encountered them. Unfortunately, they still constitute a forlorn chapter in therapeutics, medical treatment being of little value save in the gummatous variety, and it is generally agreed that only one case in twenty is amenable to surgical interference. Judged by my individual experience, the percentage is even less than this. This is quite a different position to that which every one who spoke of the subject held a few years ago. After Godlee and Bennett and Horsley demonstrated that the skull could be opened, the cavity more or less explored, and the tumor removed, cases of brain tumor were encountered more enthusiastically than they are to-day, and many reports of successful operation were published. Experience and time have shown that the glowing promise of the surgeon has not been realized. The reason thereof is not difficult to give. It is due to the commonest characteristic of intracranial growths, malignancy; their commonest mode of extension, infiltration; their frequent location in portions of the brain that are inaccessible to the surgeon; and, finally, to inability on the part of the physician to locate them, because of the indefiniteness of the symptoms and other clinical phenomena.

The question, What promise does surgery hold out in the treatment of tumors of the spinal cord? is quite a different matter. Although we have not as yet had sufficient evidence to warrant a final decision, the trend of testimony is to show that the surgeon's field for usefulness is larger in spinal-cord tumor than in brain tumor. It will be larger still when the diagnosis of the former is made with more certainty and frequency. Tumors of the spinal cord offer much greater difficulty of diagnosis than those of the brain. The latter are almost constantly attended by a symptom group, made up principally of headache, vertigo, vomiting, hebetude, apathy, staggering, spasm, or paresis of an extremity and optic neuritis, which can scarcely be paralleled by any other condition. On the other hand, tumors of the cord have no such constant clinical picture, and to make the diagnosis much more minute observation and closer analysis are called for than when the brain is similarly affected.

Although the study and report of brain tumors do not add to our capacity to deal with them more successfully, they may do so indirectly by contributing to readiness of diagnosis, and thus to early treatment. Such study may materially add also to our knowledge of the functions of the brain. Despite the fact that brain tumor usually calls forth symptoms that are so constant and significant that they are called cardinal, there are many cases in which these symptoms are absent. In attempting to localize a new growth within the skull, we depend almost entirely upon focal symptoms. Unfortunately, in not a few cases it is found on the autopsy table that such focal symptoms are misleading. The functional topography of the brain is not so well known as one might infer from reading hastily our books on localization. There are still vast regions of the brain that have no special or definitely allocated function, and it is the trend of one school of psychologists to deny that different parts of the brain are concerned uniquely with different functions. It may be said in passing that this teaching is steadily gaining adherents. Careful observation of tumors of the so-called silent regions is bound to give most valuable aid in settling some of the questions that are baffling the localizationists and the psychologists.

From the number of cases of tumor of the nervous system that have come under my observation in the past two years, and upon which an autopsy was made, I have selected the following: Each one presents, I believe, some feature that makes it worthy of record. I shall follow the recital of each case with a few remarks:

Case I.—Tumor of the Pons; Angio-sarcoma.—Summary: Sudden onset of apoplectic symptoms; vertigo followed by loss of consciousness, lasting two hours, no hemiplegia. Later vertigo, diplopia, headache, progressive ataxia of the left side, dysarthria, dysphagia, nausea, and occasional vomiting, the symptoms increasing from week to week. *Examination:* Paralysis of both abducens, paresis of the right seventh nerve, hyperesthesia in the domain of the right fifth nerve; pronounced ataxia of the left extremities, with progressive impairment of strength; exaggeration of the tendon jerks, ankle clonus, and the Babinski phenomenon (extension of the big toe, and flexion of the small toes, with drawing up of the thigh on irritating the sole) on the left side, and some exaggeration of the tendon jerks on the right side. Duration of illness, ten weeks. Death under auspices of intracranial pressure.

The patient, a married woman, forty years old; was seen October 27, 1900, with her physician, Dr. W. A. Seimel of Brooklyn. Her family history was negative. From childhood until the present attack she had been quite well, save that for the past five or six years she had suffered from indigestion, and occasionally she vomited after eating. There was no history of intemperance or of venereal disease. She had borne several healthy children, and had worked hard in bringing them up.

The story of her attack was as follows: On the evening of August 24, 1900—*i.e.* two months before she was first seen by me—she went to a dance. The night was hot. After having danced once around the room, she experienced a fulness of the head and increasing vertigo. While endeavoring to get to a seat she fell to the floor unconscious, in which state she remained about two hours. At the end of that time she was well enough to be assisted home. Save for some dizziness she maintains that she could walk fairly well. Her head continued to feel heavy. The next day she arose and started to do her housework, but she soon had to go back to bed. She found that she was dizzy, unsteady on her feet, and that at times she saw double. She began to menstruate that day, the flow being a week in advance, but otherwise normal. During the next three weeks she grew gradually worse, the left extremities becoming clumsy and weak, and she had two attacks resembling the first, but much less severe, i. e., she got a peculiar feeling of fulness of the head, accompanied by vertigo and transitory loss of consciousness.

Most of this time she remained in bed, essaying occasionally to arise, but always with the same result. For a short time after this the symptoms seemed to be quiescent, she was about the house somewhat, but at the end of September she had to keep the bed constantly, the chief symptoms being headache, dizziness, some difficulty in swallowing, with occasional regurgitation of fluids through the nose, nausea, and the ataxia of the left side already mentioned. These were the principal symptoms on October 27, the date of the first examination, but in addition she had difficulty in articulation, the speech being typically inebrieuse, and a sensation as if her face was in a mask. She was troubled, also, with palpitation. On close questioning and repeated inquiry, the patient recalls that for some days, possibly a week before the evening of the dance, she had some vertigo, and thought there was something wrong with her eyes, but the symptoms were not of such severity as to give her any concern. The following is a transcript of the notes of the physical examination made at the first visit:

Physical examination.—Eyes. Paresis of both external recti. Diplopia. Images side by side (to outer side). Convergent strabismus, left pupil larger than right. Pupils react to light and in accommodation. No evidence of conjunctivitis. Sensibility of the cornea seems keen. No optic neuritis.

Face.—Left facial innervation greater than right. Right side of the face is immobile. Upper branch of facial less involved. On emotional display same facial inequality. Dermographic character of the skin marked (more on right). Partial loss of the sense of touch over the left fifth nerve. Sensibility of the right side of the face somewhat obtunded. Sense of smell unimpaired.

Palate.—Immobile. Tongue, thickly coated, light brown. No tremor. Moves it with effort. No atrophy.

Head.—Large. Forehead bulging. Fontanelles bulging. Percussion of skull, duller on the right side than on the left. Extreme sensitiveness over the occiput, especially on right side, and around the foramen magnum. No disturbance of hearing.

Upper extremities.—In the left upper extremity the motor power is markedly diminished, and the ataxia is very striking. The entire musculature of left upper extremity is much less than the right (flabby). The left upper extremity is flaccid and there is no resistance to passive motion. The left wrist and triceps jerks are exaggerated; those of the right side are lively.

Abdominal reflexes cannot be elicited. The patellar reflex is exaggerated on both sides, but especially on the left. Tendon Achilles reflex ditto. Plantar reflex markedly exaggerated (with lively extensor responses), especially on the left side. Babinski reflex marked on the left side, but it cannot be elicited on the right.

Ankle clonus very lively, especially on left side. Increased resistance to passive movement in left lower extremity. Musculature of both sides very flabby, especially on right side. Motor power diminished on both sides, especially on left.

She was seen again a week later. The symptoms were the same as before, only more severe. The physical examination revealed nothing further, save that the ataxia of the left extremities was now associated with diminished motor power, amounting almost to paralysis, and there was diminution of sensibility on the left side of the body and the right side of the face. The ocular and facial conditions are the same as mentioned in the notes of the first examination. There was slight sluggishness of reaction to the faradic current in the right facial nerve. There were no evidences of choked discs. When the patient was lying quite still, with one eye bandaged, she seemed to be without much pain. The moment she stirred or was moved, she was agonized with vertigo. As her vital forces became impaired, she began to be semi-stuporous and lethargic. She died on the 9th of November, the symptoms that preceded death for a few days being those of a lesion of the oblongata.

I opened the cranium a few hours after death and removed the brain. The appearance of its exterior and its membranes was quite normal. There was no sign that excessive intracerebral pressure had existed, and the ventricular system was of normal shape, size, and content, when the brain was laid open. A cross-section made through the middle of the pons showed that the right half of this segment of the nervous system was almost entirely usurped by what seemed to the naked eye to be a cystic area, or an area of acute softening. The left half of the pons was apparently slightly affected in a similar way. No further examination was made until the brain was ready for microscopical examination, when it was found that the apparent softening was an angiosarcoma.

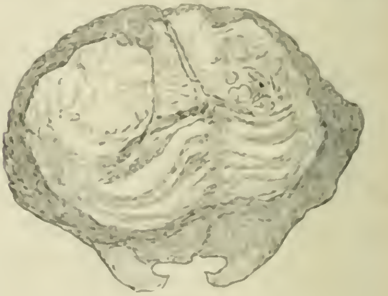

FIG. 1.

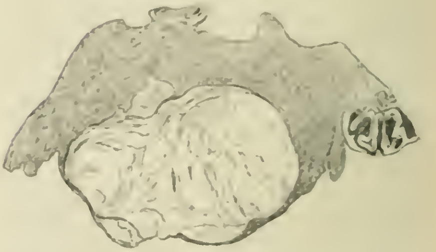

FIG. 2.

The tumor occupies the lower part of the pons; that is, the pons proper. At about the middle (caudo cephalad), it occupies the whole width and height of this level, leaving only a border of about ½ cm. free on all sides (Figs. 1 and 2). It is most extensively developed on the right side. It extends from the very beginning of the pons (encroaching even slightly on the middle of the pes pedunculi), throughout its entire length, and terminates at the oblongata at the level of the twelfth nerve; but it does not include this level.

Both abducens nerves are taken in by the tumor. The right facial nerve, which passes directly through the tumor, appears entirely degenerated (brown in Weigert, white in Pal, specimens). The left facial nerve seems to be compressed and thin, but its fibers take the stain deeply.

The right eighth nerve does not seem involved, or, if so, at least only its anterior root. The left eighth nerve is entirely intact.

The ninth nerves (evidently also the tenth and eleventh nerves) of both sides are entirely beyond the domain of the tumor, as is also the vagoglossopharyngeal nucleus and the solitary fascicle on both sides.

The twelfth nerves and nuclei are likewise entirely spared. The spinal root and the gelatinous substance of the right fifth nerve are wholly replaced by the tumor mass; on the left side, they are involved to a comparatively slight degree.

The fifth motor nuclei seem intact, likewise the outgoing roots.

The third and fourth nerves and nuclei are intact.

The fillet and formatic reticularis, especially of the right side, are strongly pressed upon, the right side being much distorted, but not otherwise involved.

The tumor being most extensively developed on the right side, the raphe is curved over to the left (*id est*, with convexity to left). The mesial portions of both trapezoid bodies are impinged upon by the tumor. The lateral portion of the right trapezoid is unusually thin, as if it had been compressed upon both sides. The cerebellum, restiform body, the superior and middle peduncles are intact.

Below the facial region, the lesion is almost entirely confined to the right side, involving exquisitely the region of the anterior pyramidal tracts, reaching a little beyond them. The secondary degeneration produced in the right pyramidal tract is striking in cross-sections of the oblongata.

The nature of the tumor is that of a sarcoma, which is very vascular, the blood vessels forming in some places great networks of dilated, tortuous masses, the dilatation being aneurysmatic in character in many places. The tumor shows a number of large softenings, a few of them being seemingly of older date, partly organized; others, evidently of recent date, show clearly as extensive hemorrhages. It is interesting to note that, in the midst of the tumor and throughout it, a large number of nerve fibers is preserved.

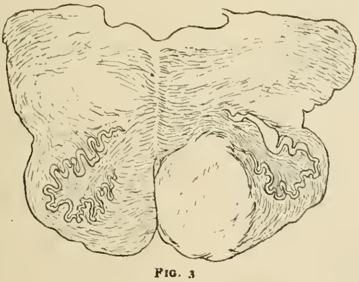

FIG. 3

The finer microscopical structure is typical of angiosarcoma, and needs no further description. The secondary degeneration produced in the right pyramidal tract is well shown by figure.

The case is of interest not only because of the difficulty of diagnosis which it presented, but because of the course of the disease and the proof that it seems to offer that the pons can be the seat of extensive disease in the shape of a tumor for a considerable period without causing symptoms of any severity. It reminds one in this respect of a case of tumor of the oblongata that was reported a few years ago by the writer in the *American Journal of Medical Sciences.* The mode of infiltration of the neoplasm, leaving so many fibers functionable even to the end, and the absence of œdema account for this feature of the case. When the patient was first seen, a diagnosis of acute softening in the right half of the midpons was made, but the probability that it was a tumor increased with opportunity to observe the patient.

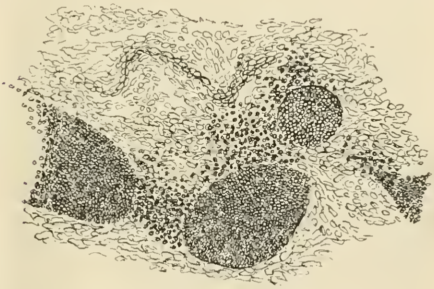

FIG. 4.

Tumor of the pons in the adult is a very rare disease, and especially angiosarcoma. Tuberculous growths in and upon the pons are not very uncommon in childhood. The symptoms of pons-tumor are supposed to be very characteristic, because this small segment of the nervous system contains in close juxtaposition the nuclei of the fifth to seventh nerves, the central pathway of the eighth to twelfth nerves, and the sensory and motor pathways for the body and the extremities. The pathognomonic symptoms are one form or another of so-called alternate hemiplegia; *i. e.*, one side of the face (the seventh nerve, more rarely the sensory branches of the fifth), and the contralateral extremities, associated with inability to glance toward one side (the side corresponding to the half of the pons that contains the tumor). When the lesion is in the lower segment of the pons, the function of one hypoglossal nerve (the one on the side of the paralyzed extremity) is impaired up to complete abolition.

A number of variations of this form of paralysis (often called Gubler's paralysis) have been described, but it is not necessary to mention them here.

The most striking symptom that this patient presented was unilateral ataxia. It existed from soon after the beginning of her illness to the end, and only for a short time before death was it associated with paralysis. In its clinical features, it resembled the acute ataxia that one sees occasionally associated with anæmias and cachexias. It is an extremely uncommon accompaniment of tumor of the pons. Its occurrence therewith is conditioned by lesion of certain fibers or pathways of the fillet, the central sensory pathway. Other noteworthy clinical features were absence of choked discs, of reaction of degeneration in the right seventh nerve, and of pressure symptoms. It has already been suggested that the mode of infiltration accounts for these. The sense of hearing, which one might likewise expect to find impaired, seemed to be intact.

Looked upon wholly as a tumor growth, one is impressed with the fact that it is unlike most sarcomas of the central nervous system, so that they do not tend to ulcerate; they grow to a solid mass.

The mental symptoms which the patient had, and the different [illegible], are readily explained [illegible] upon the different hemorrhages and consequent softenings which were to be seen in the specimen (see Fig. 4).

A case of brain tumor which was regarded by me for a short time with great interest, because of the fact that many of the symptoms seem to indicate pons involvement, was the following:

Case II. – Tumor of the Left Hemisphere, Anterior pole; Syphiloma. – F. P., twenty-eight years old, a Russian Pole, was admitted to the New York City Hospital on March 9, 1899. Very little could be learned of his personal history, because of his forgetfulness. His parents are living and well, and there seems to be no family history of any interest. The patient does not recall having had any of the diseases of childhood, and he says that he had never been so sick that he had to remain in bed before this attack. He has not been addicted to excesses of any kind, although he has worked hard as a laborer, and has been very much exposed to changes of temperature and inclemencies of weather. Nearly two years ago he had a chancre. He does not know whether it was called hard or soft, but he is sure that there was no cutaneous eruption, no loss of hair, no sore throat, and other common secondary manifestations. He was treated until the chancre got well, but not after that.

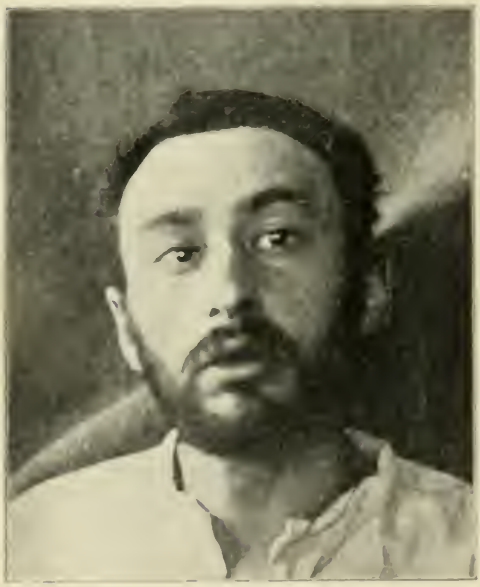

FIG. 5.

The only history of the present illness that can be obtained is that he thinks it came on suddenly. Headache, he says, has never been a symptom, nor has he vomited. He does not recall coming to the hospital. He was able to walk when he entered, but it is noted that he was very weak and shook all over for several hours after his entrance.

The following is a transcript of the notes made on April 3, 1899, when I first saw the patient. The man is of stupid, emotionless appearance, the features being listless and expressionless (see Fig. 5). There is an apparent convergent strabismus, due to paralysis of the external rectus. He is unable to move the right eye outward beyond the median line, and this eye remains immobile on attempts at convergence. The left eye seems to be freely movable. The pupils react to light very sluggishly. Ophthalmoscopic examination shows well-marked choked discs, with beginning nerve atrophy of the left eye, the right being apparently normal. There is continuous fine tremor of the face and tongue when the patient essays voluntary movement. There is profound anæsthesia over the area of distribution of both fifth nerves. This anæsthesia and analgesia is more marked on the left side. It is impossible to acquire reliable information concerning the state of the functions of smell and taste, for the patient cannot be made to take any interest in the examination. The sense of hearing seems to be preserved on both sides. There is no ataxia of the upper extremities. The lower extremities, and particularly the muscles of the buttocks, are often in a state of profound tremor or agitation, such as is sometimes seen on exposure to cold. The knee-jerks and the ankle-jerks are exaggerated, more so on the right than on the left side. The patient seems to be incontinent of urine and occasionally of fæces. Tests for cutaneous sensibility shows that although the patient is not acutely sensitive to the prick of a pin, he resents it by word and by gesture, except when the face is pricked.

Two days later it is noted in the history that the knee-jerks are very sluggish, and in fact, scarcely elicitable. The face seems very insensitive when a pin is jabbed into it. On the following day the knee-jerks were sluggish, but the right was more easily elicited than the left. On this day it was noted that he could feel a pin when it was stuck into the skin of the face, and that the sensibility of other parts of the body was more acute than usual. On April 12 it was noted that the knee-jerks were absent on both sides, while on the next day they were somewhat exaggerated, and I was able to elicit well-marked ankle-clonus. On the evening of this day the patient seemed to have a violent chill, and he put on the appearance of collapse. He became so apathetic that he could scarcely be aroused. The breathing was shallow, and the pulse accelerated. It was also noted at this time that there was a striking difference in the surface temperature and color between the right and the left side. The right side was red and warm, the left cold and white. At this time, there was pronounced tremor of the right hand, and a considerable rigidity of the right upper extremity. The knee-jerks were exaggerated, and it was possible to elicit ankle-clonus. The patient remained in this condition the next day, but gradually became so apathetic that he could not be aroused, and on April 15th he was in a condition of profound coma. The discharges from the bowels and bladder were both of a bloody nature shortly before the patient died. Study of the pulse during the time the patient was in the hospital, six weeks preceding death, shows that for the first few days of this time it beat from 60 to 70 times per minute. Then, without apparent cause, it became very much accelerated, averaging about 85 per minute, occasionally going up to 100, and again dropping as low as 70. During the week preceding death, it varied from 120 to 160 per minute, it having reached the former figure before the chill with which he was taken three days before death. Respirations were somewhat accelerated during the entire time that he was under observation, 20 to 22 per minute. Until the chill occurred, there had been no elevation of temperature, nor subnormal temperature. For four days preceding death the temperature was about 105.

No signs of pneumonia could be made out by physical examination.

Autopsy, made thirty-nine hours post mortem: The body of a fairly well-nourished man. No scars or marks on the cutaneous surface save a slight scar on the glans penis. Post-mortem rigidity well marked in the lower extremities, beginning to disappear in the upper extremities. When the calvarium was removed, it was found to be very thin, especially over the left frontal region. There was some difficulty in getting it away after it had been cut through, on account of adhesion of the dura to the bone over the left frontal region. When removed, the internal surface of the calvarium showed the thinness of the bone at this point, and gave a condition of the skull which looked like sieve-depressions. After the skull-cap had been taken off, a large granular-looking mass was seen in the anterior pole of the left hemisphere (see Fig. 6).

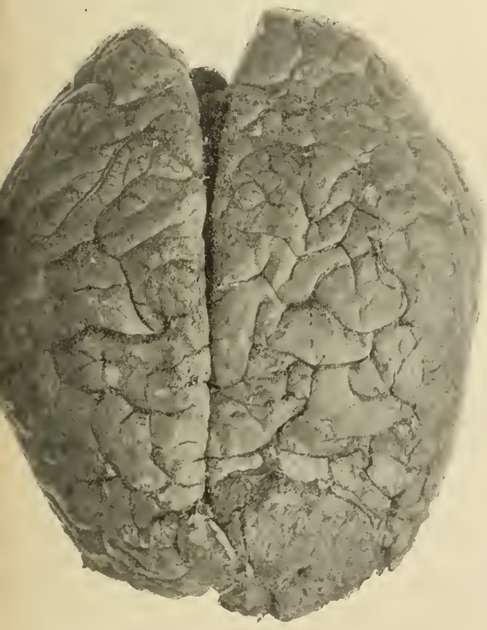

Fig. 6

When the brain was removed, it was seen that this granuloma, the size of a hen's egg, was firmly attached to the dura, and usurped the substance of the first and second frontal convolutions, extending backward as far as a line reaching from a continuation of the ascending limb of the fissure of Sylvius up to the longitudinal fissure. In front and below it was nearly limited by the frontomarginal fissure. The remainder of the cortex seemed to be normal. Examination of the inferior surface of the brain showed no particular abnormality. The left lobus rectus seemed smaller than the right and somewhat flattened out, as did the olfactory bundle of that side. The optic chiasm was of normal appearance. The anterior perforated space was free, and bridged over by a layer of thin pia. The pons and oblongata seemed to be entirely normal.

So far nothing had been discovered to account for the nuclear symptoms which this man had, and which are distinctly apparent in the photograph (Fig. 5). The case was looked upon as one of the syphiloma of the pons, particularly on account of the well-marked analgesia over the fifth nerve and the ocular symptoms. Although it was borne in mind that the apathetic condition in which he was precluded very accurate investigation, yet it was not at all suspected that the patient had a tumor of the frontal lobes. The variability in the knee-jerks and the accession of clonus was thought to indicate an encroachment upon the motor areas or fibers of the pons. It did not seem that any other explanation save the existence of tumor within the pons could be made to explain the paralysis of the right external oblique, the slight amount of ptosis, the anæsthesia in the area of the distribution of the trigeminal, and the peculiar expression of the face. These, taken in connection with the mental apathy, were thought to be peculiarly suggestive. The patient's mental condition was very much like that described by all writers on brain tumor as indicative of pons lesion (*vide* Case No. 1). He would lie in a more or less fixed position for hours at a time, capable of arousing himself or being aroused, of answering a question, but often lapsing in the middle of the answer. Tumor of the frontal area was not suspected for the reason that none of the cardinal symptoms of brain tumor were present, and because the only localizing symptoms that existed pointed to involvement of the basal structures. The skull had been carefully percussed on different occasions, and nothing approaching difference in percussion note was ever obtained over the area which was later found to be the seat of tumor. One of the most impressive lessons of the autopsy was that the tumor was an extremely removable one, if we had been able to locate it. It was not of the brain substance at all, but grew from the dura, usurping the cortex on which it encroached. Another interesting fact is that large doses of iodide did not seem to have any effect on it, nor did small doses, for that matter.

Case III.—Sarcoma of the Cerebellum in a Child.—The male child, six and one-half years old, from whom the specimen depicted in the accompanying sketch (Fig. 8) was taken, was brought to my clinic at the Post-Graduate Medical School on January 31, 1899, where he had been sent by a physician to be treated for neurasthenia. It was learned from his parents, in whom there seems to be no evidence of disease, that when he was four years old he had an attack of measles, followed by slight discharge from one of the ears, which quickly subsided. After this, he had symptoms of catarrh of the stomach which did not yield readily to treatment. Apart from these he was well until the onset of the present illness, which dated back about one year. The history is that without apparent cause he sickened with headache, which was soon followed or accompanied by attacks of vomiting. The headache increased in severity for about a month, and the vomiting seemed to keep pace with it, for it is reported that he had from one to three severe attacks of vomiting each day during two months. For the first few days after the symptoms came on, he had to remain in bed, but later he was about the house and out of doors. After about three months the attacks of vomiting ceased, but the headache continued. In addition to these symptoms the child seemed to be very weak, and was treated for neurasthenia in a desultory fashion. Gradually the headache got less severe, and for a month before coming to the clinic he had not complained. The parents said that they brought him that he might get relief from pain in the hands, feet, and neck, particularly the right hand. The character of the pains he was not able to describe. Apparently, the pains were intermittent, the exacerbation lasting about one-half hour. During this time he would throb and the parents say the right hand would tremble. At times he complained also of headache but there had been no vomiting for several months.

Examination showed a fairly well-nourished boy, who clings to his father in fear of falling. The eyes are staring and the face expressionless, better said, the emotional muscles are relaxed. When he attempts to stand slight titubation is apparent, and when he essays to walk, he staggers in a reckless sort of way, as if he had no control over the lower extremities. He can use both hands, and apparently there is no ataxia or amyosthenia of the upper extremities, although he does not use the left hand as freely as the right. The knee-jerks are elicitable on both sides. Without reinforcement, they are rather sluggish. The ankle-jerks are likewise elicitable. There was no paralysis of the lower extremities, but the muscles were in a toneless, flabby condition, even when he attempted to walk. He passes urine and fæces without concern, in bed or in his clothes, wherever he may happen to be. Mentally the child seems to be all right. He answers questions readily and correctly, and indeed seemed to have greater mental capacity than many children of his age and social grade.

Examination of the eyes showed an internal strabismus, apparently due to paralysis of the right abducens, which the parents said they had noticed first five months before. The pupils were widely dilated, and slightly responsive to bright light. Vision was reduced to perception of large objects held immediately before the eyes. Ophthalmoscopic examination showed double-choked disks, the elevation of the right being somewhat greater than that of the left. No disturbance of the sense of hearing or the senses of smell and taste could be made out.

CLINICAL CHART.

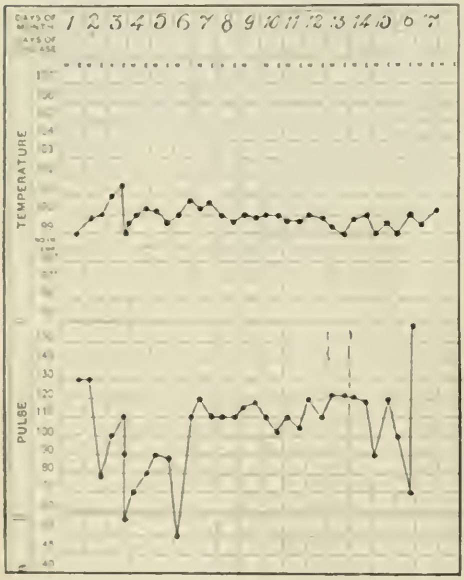

Fig. -

A diagnosis of cerebellar tumor, probably vermicular, was made, and the child sent into the hospital. His condition did not materially change for the first few days, but after about a week he began to be somewhat restless and sleepless, while the inability to stand and walk became so great that when put upon his feet, he tumbled about in the most reckless fashion. Mentally, however, he remained quite clear.

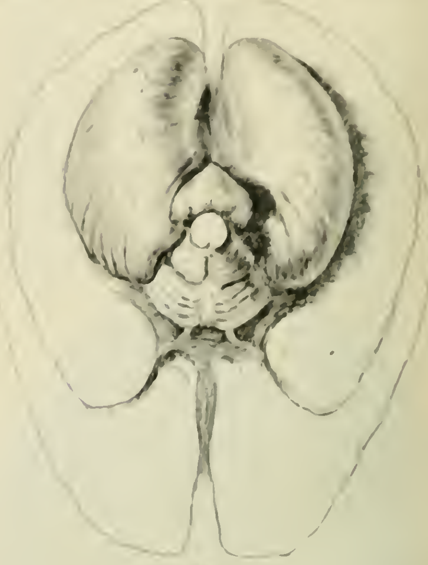

Fig. 8

This was markedly in contrast with the complete indifference with which he constantly wet and soiled the bed. While in the hospital, it was noted that the strabismus was by no means constant. At times it would seem to completely disappear. The facial expression, however, became more typical of brain tumor, and the slightly deficient innervation of the right side of the face, which had been noticed on first examination, became more evident. Two weeks after he was first seen, he became worse, somewhat abruptly. He vomited his breakfasts, the strabismus became very marked, and the temperature rose to 100°. Dr. A. E. Davis, who at this time kindly examined his eyes, corroborated the findings mentioned above, and reported an elevation of each papillæ of about six diopters, the veins of the fundus somewhat enlarged, and extravasations of blood on and near the discs. The pupils were widely dilated and not responsive to light, and vision in both eyes was reduced to perception of light. During the night following this examination he was delirious, but the following day he talked very sensibly and complained of frontal headache. The following afternoon he passed into a condition of collapse, and died late in the day under the auspices of respiratory failure. A temperature chart showing the fever and pulse variations is herewith appended, covering the entire time during which he was under observation, viz., from the 1st to the 17th of February. It might be said that repeated examinations of the urine showed no noteworthy departures from normal, except a rather constant high specific gravity.

The autopsy, made twenty four hours post mortem showed no abnormalities of the cranium, except that it was thinner in spots than crania of six-year-old children usually are. The membranes and their blood vessels seemed to be normal. The brain was not distended, and as it lay in the skull cavity it appeared quite normal. Upon removing it, there was seen posterior to the upper border of the oblongata, and lying between the lobes of the cerebellum a mass the size of an English walnut or of a pigeon's egg of irregular lobulated appearance, pinkish in color, with numerous small blood vessels running across its surface (Fig. 8). It had no attachment to the oblongata, but projected from between the hemispheres of the cerebellum, having its origin from the posterior end of the inferior worm, and extended through the vallecula for nearly an inch. The pressure which it caused upon the right amygdala was plainly apparent in the atrophy of that portion of the cerebellum and in the postero-inferior lobe, which causes the entire right hemisphere to look smaller than the left. The tumor was enveloped in the pia, and in the recent state the arborizations of the vessels seen in the congested state were very striking. The tumor was more resistant to the touch than the brain substance, and to the naked eye it had the appearance of sarcoma. This was corroborated by microscopical examination, the shape of the preponderating cells being round.

The case offers very little to comment upon, save to point out the infrequency of this variety of tumor in a child so young, and the non-characteristic symptoms which led to the boy being treated for neurasthenia. It should teach us that we must not expect all the features of the typical clinical syndrome in every case, and that the diagnosis need not depend upon the existence of the fully portrayed typical picture.

Case IV.—Sarcoma of the Right Lateral Ventricle.—Mrs. E. S., a Swede, twenty-four years old, was sent to me on May 8, 1898, by Dr. F. K. Halleck, with the request that she be admitted to the City Hospital under my care, in order to determine the location, and, if possible, to operate upon the brain tumor which he had diagnosticated. The history of the patient was that she had been in good health until November, 1897, that is, about seven months before coming under my observation. The initial symptoms seem to have been pain all over and through the head, which she calls neuralgic. At one time the pain would be most severe in the forehead, at another time in the occiput, sometimes in one eye; but it soon became so severe that she was unable to localize it. This pain came on suddenly, and she recalled that she was awakened one morning by it, and that it lasted for about four hours and then disappeared. After remaining free from it a few days, it reappeared, and soon became so unendurable that she went off her head, becoming delirious and hallucinatory. After the pain had subsided somewhat, the delirium and visual hallucinations would disappear. When the headache was most severe she vomited, and she was almost constantly nauseated, although when the pain alleviated this would disappear. The next complaint was of indistinctness of vision, and then it began to be suspected by the physician who was treating her that there was an organic lesion, and she was placed upon iodide of potassium, although it has been impossible to learn the doses or quantity that she took.

There is no history of the occurrence of convulsion, spasm, or tremor, nor has there been any disturbance of gait that could not be explained by the progressive blindness. She has been able to use the extremities as well as usual, except for general weakness, which has developed gradually since the beginning of her illness. Aside from the failing eyesight, there has been no complaint of disturbance of any of the special senses. Her husband states that she has gradually lost interest in herself and her family, and has become irritable, peevish, and childish.

The subjective symptoms were, therefore, very few, and consisted of (1) Headache of abrupt onset, of unendurable and paroxysmal severity, associated at its height with visual hallucinations and delirium; (2) Nausea and vomiting, particularly during the most intense headache; (3) Obscuration of vision; (4) Dementia.

Examination revealed a fairly well-nourished woman, whose face bore the evidences of prolonged suffering, and at the same time a vacant, fatuous expression. The head was hanging, the eyes partly closed and shielded with colored glasses. She was apparently six months pregnant. She had made a journey of about a hundred miles the day I first saw her, but despite this, she seemed in fairly good strength. Objective examination revealed absolutely no departures from the normal, save that of the ophthalmoscope.

In the left eye there is distinct choked disc with connective-tissue formation, especially toward the center. The right eye shows less swelling of the disc, but greater enlargement of the veins, and the beginning appearances of post-inflammatory atrophy.

The cranial nerves seem to functionate normally. There is no disturbance of the motor or sensory spheres. Muscle tonus as manifest in the knee and ankle jerks seems to be unchanged.

A diagnosis of subcortical tumor, ventrad to the pyramidal projections, was made, and operation, save trephining for the relief of pain, advised against.

The patient went to her home for a few days, but was later admitted under my care to the City Hospital. Three days after my first examination, she had an attack of a syncopal nature while sitting at the table taking dinner. The knife and fork which she held dropped from her hands, and she seemed as if about to lose consciousness. Then the face became pale, and she was immediately taken with a severe headache and an attack of vomiting.

Her condition while in the hospital did not materially change, except that the headaches and vomiting ceased; but she gradually got less alert psychically, although she answered questions correctly and with considerable readiness, providing they required no further effort than statement of her feelings or needs. She rarely took the initiative in conversation with other patients, nor when members of her family visited her. She seemed to thrive fairly well, and there was every indication that she would not only survive till the time for the normal birth of the child, but beyond it. Pulse, temperature and respiration were quite normal. On the evening of the 11th of June, it was noted that she became restless without apparent cause, and that the temperature was slightly elevated, although there was no evidence of inflammatory process anywhere. She continued to grow restless and weaker, and it was decided to deliver the child, which was done by rapid dilatation of the cervix by means of Barnes dilators and the performance of version. The child, a good seven months' specimen, lived seventy-two hours. The mother died within twenty-four hours without attributable direct cause. The ante-mortem temperature was 106° F.

Autopsy showed normal conditions throughout the body and brain, save for a sarcoma about the size of a hen's egg in the anterior, one-third of the right lateral ventricle growing apparently from the ependyma of the floor (Fig. 9). Both ventricles were considerably dilated, and about four ounces of fluid escaped when they were cut into. The location and extent of the tumor is very well represented by the accompanying photograph.

From consideration of the symptoms and by process of exclusion the tumor was located approximately, but there was not enough certainty about it to warrant asking the surgeon to search for it.

Although the autopsy showed that the growth was in the situation to which it had been allotted, it showed also that it could not have been removed. The symptomatology of tumors of the lateral ventricles is not well established. In the first place, there is little literature on the report of such cases, and in the second place, they are not of frequent occurrence. In this case there was not a symptom that can be looked upon as suggestive of the location of the tumor unless the peculiar paroxysmal headaches might be thus interpreted. The visual hallucinations have not, I think, been heretofore noted with tumors in the region.

The last case of brain tumor that I shall speak of in this connection amply illustrates the difficulty that may be experienced in attempting to diagnosticate the nature and location of intracranial growths.

Osteosarcoma of Long Duration.—M. V., a married lady, fifty years old, was first seen on February 18, 1897. Her history was that the illness for which she now consulted a physician was of five years' duration. The initial symptoms were severe, darting pains in the left side of the head and left eye, and gradual loss of sight and of hearing on the left side. After these symptoms had existed for about one year, she had a convulsion. Previous to the convulsion, she had a number of attacks of loss of consciousness, lasting for several minutes, and it is not improbable that these symptoms antedated the pains in the head. After the first few convulsive attacks she seemed to become somewhat dull and forgetful, and this has continued to the present time. It was for the relief of the epileptiform manifestations, the headache and hallucinations which she seemed to have at times, that she was brought to me.

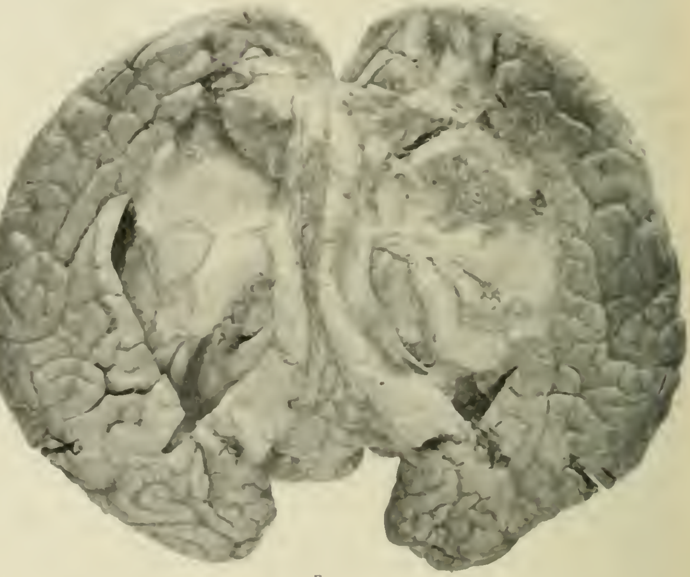

Fig. 9.

Examination at that time showed marked protrusion of the left eye, decided limitation of ocular movements to the left and upward, some drooping of the left lid, immobility of the left pupil on exposure to light, nystagmus of the left eye when looking toward the right. Ophthalmoscopic examination of the right shows normal papilla. Sensibility over the left side of the face was diminished. There was no motor paralysis and no ataxia. The patient apparently understood everything that was said, and there were no symptoms of aphasia. There was a rapid fine tremor of the hands. The knee-jerks were lively, and the plantar reflex about normal. Persistent tachycardia; the pulse ranged from 104 to 120, the left lobe of the thyroid gland enlarged. She complains that she always feels warm, and the face is often flushed. She was put upon iodide of potassium in increasing doses up to 60 grains t. i. d., but her condition continued practically unchanged. The convulsions occurred from time to time, but she was able to look after her household with a good deal of satisfaction.

On November 22, 1898, she was seen again. The report was that she had been improved in health until within the past week, when she began to complain of severe pains in the left side of the head. She still has attacks of unconsciousness, attended at times with convulsions. There is no tremor. The left exophthalmus is more marked than when she was seen before. The thyroid seems to be normal, although the pulse is 140. The patellar reflex is normal. There is no anæsthesia. The patient was not under my care, and there are no further notes of the case save that she developed signs of Bright's disease during the winter of 1899 and died from that disease.

Autopsy, May 1, 1899.—Body emaciated. Protrusion of contents of left orbit. Skull is distinctly asymmetrical, due to lateral enlargement, principally over left parietal region. On removing the skull-cap, the dura is seen to be thickened and engorged, especially on left side. The left parietal convolution is voluminous, due to œdema, and occupies more than one-half of the cranial cavity. Over the apex of right temporo-sphenoidal lobe the brain is adherent to the dura of the middle fossa. On the left side, in the region of the temporal lobe, the brain is firmly attached to the adjacent bones by a firm growth. This growth involves the inner one-half of the petrous portion of the temporal bone, the adjacent body and sinuses of the sphenoidal, and pushes forward into the posterior portion of the left orbit, and downward through the foramen Magendie as a fine chain-like mass, but apparently not involving the oblongata. The left hemisphere, which was infiltrated with serum, was so extremely soft that it was lacerated in manipulation. On removing the brain, the distended left ventricle became collapsed, through loss of the intraventricular fluid. Evidently, the growth involves the basal portion of the left temporal lobe, especially the two lower gyri. The dura was intimately adherent to the pia, especially over the motor area of the left hemisphere. The pia itself was very adherent, and slightly œdematous. The walls of the lateral ventricle were in apposition and seemingly stuck together, before the ventricular cavity was displayed by cutting into it. This ventricle seemed much smaller than the right. The fourth ventricle was laid open by cutting through the vermis of the cerebellum, and seemed normal. The base of the brain showed no abnormality, except that the longitudinal gyri were thin and narrow.

The case during life had been looked upon as one of tumor of the base, encroaching upon the side of the pons.

The particular interest of this case centers around the protracted duration of the disease, no less than seven years, and finally she did not die of it, but of chronic Bright's disease. In reality, the case was not one of brain tumor in the strict sense of the term, nor did it have the cardinal symptoms; still all intracranial growths must be reckoned with brain tumors. The causation of the epileptic attacks was not disclosed by the autopsy. The growth did not encroach upon the motor areas, and the epilepsy cannot, therefore, be looked upon as an irritation symptom. Any speculation that one might be tempted to indulge in regarding the possible dependency of the epileptic attacks upon paroxysmal œdemas of the brain similar to that found after death, particularly in the left hemisphere, would be quite useless, for the patient had ascites for a considerable time before death. It is particularly noteworthy that the patient had the subjective symptoms of Grave's disease, and the prominent physical signs of this neurosis on one side of the body.

LATENT AND MASKED MALARIAL FEVERS.*

ANALYSIS OF ONE HUNDRED AND NINETY-FIVE CASES.

By CHARLES F CRAIG, M D.

CONTRACT SURGEON U. S. ARMY; PATHOLOGIST AND BACTERIOLOGIST TO THE U. S. ARMY GENERAL HOSPITAL; PRESIDIO OF SAN FRANCISCO, CAL.

One of the most important duties of the medical practitioner of to-day is the diagnosis of the various forms of malarial fever. This is so from both a therapeutic and a prophylactic standpoint, for, in the light of our present knowledge of malaria, it is most important to ascertain whether or not the disease exists in certain localities, and what forms of it are present.

In all probability, malarial fevers will be found to be more prevalent in the United States during the next few years than ever before, due to the large number of infected soldiers returning from the Philippines and Cuba. Places never before malarious will undoubtedly become so, for all that is needed to spread the infection is an infected individual and the presence of mosquitos of the genus *Anopheles*. Not only will the mild tertian infections become very numerous, but the severe estivo-autumnal fevers will be introduced in new localities, as a very large percentage of our returning soldiers are infected with the estivo-autumnal parasites.

Never before in the medical history of our country has a knowledge of all phases of malariology been so important and necessary to the general practitioner as at the present time, and I cannot urge too strongly upon the profession the necessity for constant and careful investigation of all irregular and obscure fevers.

The estivo-autumnal malarial fevers are protean in their symptomology, and, unless promptly recognized and treated, are very prone to become pernicious; hence the value of a speedy diagnosis, especially when it is remembered that malarial infection is often present without giving rise to typical symptoms. In all such cases the diagnosis can be made only by a microscopical examination of the blood, which should be as much a matter of routine practice in cases of fever as the examination of the urine.

The subject of latent and masked malarial fevers is one of great importance, and one which has been but little investigated. While the literature devoted to malaria is extensive and of great value, comparatively little has been written concerning this subject. It will be admitted by all students of malarial infections that many cases occur in which the symptoms are masked by those of complicating disease processes, or in which the symptoms are atypical; and it is equally true that malarial infection may exist without producing appreciable symptoms of any kind. In the first case, we say that the malarial fever is "masked;" in the second, that it is "latent."

A masked malarial infection, then, is one in which the malarial symptoms are hidden by those of some other disease, or in which the malarial symptoms are atypical; while a latent malarial infection is one in which, while the parasites are demonstrable in the blood, no symptoms of malaria are present. Regarding these forms of malarial fever Marchiafava and Bignami* say: "All physicians are aware that there are grave, and sometimes mortal, infections, in which the rectal temperature may be little above the normal, or may even be subnormal. When the blood is examined in some of these cases, we may find many parasites. The reason for this can be found only in special conditions of the patient's system; just as there may be a lobar pneumonia without elevation of temperature, especially in aged and feeble persons, so may occur grave malarial infections without fever."

"The same phenomenon occurs when, . . . usually after long duration of the infection, the patients have acquired a certain degree of immunity. In some patients we can see that, even after spontaneous cessation of the attacks, the parasites go on to the completion of their life-cycle with regularity, and even after fission and a fresh infection of parasites occur, the febrile attack is absent."

Regarding masked forms of malarial fever, Thayer† states as follows: "In a certain number of instances, malarial infections may cause distinct symptoms with little or no fever. These instances are not infrequent in improperly treated tertian and quartan infections, where the patient keeps about on his feet, taking perhaps an occasional single dose of quinine, enough to weaken but not to eradicate the infection. Here the process may be kept, as it were, in a permanent stage of incubation. There are, however, other instances where, for a considerable length of time, there may be more or less marked subjective symptoms with little or no fever. During the abortive paroxysm there may be slight flushing with a rise of temperature to a degree or so above normal, which may be followed by a little sweating, but usually fever is practically absent; the temperature really being subnormal during the greater part of the time.

"Sometimes in true pernicious cases the temperature may fall and remain normal or subnormal for some days before fatal issue. There are, moreover, principally in old infections, cases where the gravest and most fatal infections may occur almost entirely without fever."

In my work, entitled "The Estivo-Autumnal (Remittent) Malarial Fevers," I have discussed somewhat extensively the masked and latent forms of estivo-autumnal fever. The following quotations are abstracted from the chapter dealing with this subject: "In latent and masked estivo-autumnal fevers we include all cases in which the estivo-autumnal parasites may be demonstrated in the blood, but in which either no clinical symptoms are present, or the symptoms which are present are atypical in character

---

*Malaria. "Twentieth Century Practice," Vol. XIX.

†Lectures on the Malarial Fevers.

"I can recall a large number of cases in soldiers who have had their blood examined as a routine measure, in which the estivo-autumnal parasites were found, although there were no symptoms of the disease present As a rule, in such cases the number of parasites is comparatively small, but there may be much free pigment present and numerous pigmented leucocytes In blood from the spleen in the latent cases the entire human cycle of the estivo-autumnal parasites can be followed "

The tertian estivo-autumnal parasite is the most common form found in such cases, although the quotidian form is by no means rare The only explanation of the fact that the development of the malarial parasite may not, for a considerable period of time, be accompanied by clinical symptoms is either that the parasites are present in too small numbers, or that the individual infected is very resistant to the action of the malarial poison."

"The length of time during which such a latent infection may exist is as yet undetermined, but it is probable that in some cases it may be for many weeks I recall one case in which the estivo-autumnal parasites were found in the peripheral blood for six weeks before a paroxysm occurred, repeated blood examinations being made during that time. I can recall many cases in which the parasites were found for from seven to fourteen days before clinical symptoms appeared "

"The masked estivo-autumnal malarial fevers constitute the much larger class of cases, and their recognition is of the utmost importance from a practical point of view. Such cases more often present no rise of temperature, and in fact the temperature is often subnormal. Nervous symptoms, such as slight headache, vertigo, neuralgias of various parts of the body, or symptoms referable to some other disease, may be present, as diarrhœa, acute and chronic dysentery, pneumonia, typhoid fever, etc."

"It should always be borne in mind in treating diseases in localities in which the estivo-autumnal parasites are prevalent, that some of the most pernicious forms of these fevers are unaccompanied by definite paroxysms or a rise of temperature, and that the temperature is not rarely subnormal I recall a fatal case of quotidian estivo-autumnal fever in which the temperature never rose above 99° F., and in which the few symptoms present were those of an acute hepatitis. Examination of the blood a few hours before death occurred, showed large numbers of quotidian estivo-autumnal parasites, and the findings at autopsy were typical of death from pernicious malarial fever."

In this discussion of the subject I gave a brief *résumé* of 172 cases In this report it is my intention briefly to analyze 195 cases which have come under my observation in the routine examination of the blood of soldiers returning from the Philippine Islands during a period of fifteen months.

By order of Lieutenant-Colonel Girard, commanding officer of the United States Army General Hospital, Presidio, San Francisco, Cal., the blood of every patient admitted is submitted to the laboratory for examination This routine examination of the blood has proved to be of the utmost value, as time and again severe malarial infections have been discovered which did not present the usual symptoms, and many lives have been saved by the prompt treatment of such cases with quinine. I have divided the cases into masked and latent forms of the disease, but it should be remembered that a hard and fast line cannot always be drawn in many of the cases which have been observed A large number of cases showing dysenteric symptoms, in which the malarial parasites were discovered, have been almost entirely cured by the simple administration of quinine, thus showing that the intestinal condition was due to the presence of malarial infection In other cases, dysentery and the malarial infection existed together, and while the dysenteric symptoms were not cured by the administration of quinine, marked benefit resulted to the patient by eliminating the malarial element in the case

It has been impossible, in a few instances, from the clinical data obtainable, to make a strict division into masked and latent infections, making it necessary to approximate the number of cases of each class in this report This is especially true of those infections occurring in conjunction with intestinal disorders

Types of Infection —The total number of cases observed during the period of fifteen months was 195 As regards the type of parasite found, the cases may be divided as follows

1 Tertian infections		44
2 Quartan infections		1
3 Estivo-autumnal infections		150
Tertian estivo autumnal infections	117	
Quotidian estivo-autumnal infection	32	
Mixed tertian and quotidian estivo-autumnal infections	1	

From the above table it will be seen that the estivo-autumnal infections are altogether the most common This is an interesting fact because the tertian infections in the Philippines are said to be the most numerous, and as also showing that the fevers due to estivo-autumnal infection are much more apt to be masked or remain latent than those due to the tertian form. This may also explain, where routine examination of the blood has not been carried out, the relative frequency in the Philippines, as reported, of the two varieties of malaria If so large a percentage of estivo-autumnal cases are masked by other diseases or remain latent, it is seen at once how inaccurate may be our statistics, where routine blood examination is not carried out, of the relative frequency of tertian and estivo-autumnal malaria

All observers who have studied the subject in the Philippine Islands unite in claiming that the tertian infections are altogether the most numerous; but from the examination of the blood of those cases occurring in soldiers who have returned from the Philippines, my experience has been exactly the reverse, the estivo-autumnal infections being altogether the most numerous. But a large percentage of such cases were latent or masked by other complications, and would never have been discovered from the study of the clinical records alone The relatively large percentage of estivo-autumnal infections which remain latent, or are masked, also proves how important it is that the blood be examined in every case returning from or residing in a malarious locality.

Character of Parasites —The following table illustrates the various stages in the human life-cycle of the malarial parasites which were observed in the blood in these cases.

1. Tertian infections, total number		44
Hyaline stage	5	
Pigmented stage, ¼ to ¾ grown	32	
Pigmented stage, full grown and segmented	7	
2. Quartan infections, 1 case, parasite full grown.		
3. Estivo-autumnal infections, number of cases		150
Hyaline ring forms	102	
Hyaline ring forms and pigmented forms	36	
Hyaline ring forms and crescents	8	
Crescents	4	

From the above table it will be seen that the pigmented forms of the tertian parasite were generally present in these infections, and there was no difficulty whatever in recognizing the parasite. This was also true of the one case of quartan infection observed.

In the estivo-autumnal forms, however, it will be seen that the hyaline "ring forms" were altogether the most common, and as these are the most difficult forms of the malarial parasite to recognize, it will be obvious how very often such cases would be overlooked by one not accustomed to the examination of malarial blood. While there is no difficulty whatever in recognizing the hyaline forms of the estivo-autumnal parasites, when one has had considerable practice, they are generally overlooked during this stage by inexperienced observers.

The small number of cases in which crescentic forms were observed only increases my belief that the crescentic forms are not nearly as common in the blood in man as many of the writers upon malaria would lead us to believe. Certainly, these are the very type of patients in which one would expect to find crescents, but only a very small percentage show their presence. In hundreds of cases of estivo-autumnal fever which have persisted for months, I have failed to observe the regular occurrence of crescents, which many writers speak of.

Number of Parasites.—As regards the number of parasites present in the blood in the masked and latent cases, it may be said that, as a rule, they were few in number. As we have at this time no accurate means of estimating the number of malarial parasites in a specimen of blood, it is impossible to make an accurate classification. It has been my method as regards the number of parasites present in any specimen of blood, to speak of them as "few" or "numerous." In this loose classification I find that the following table represents the number of parasites present.

INFECTION.	TOTAL NO. OF CASES.	NO. OF PARASITES. FEW.	NUMEROUS
Tertian	44	32	12
Quartan	1	1	..
Estivo-atumnal	150	130	20

The above table is very unsatisfactory in a number of ways, but it is probably approximately correct. The number of parasites in a specimen of blood would, of course, vary apparently upon the length of time spent upon the examination, as the longer the time spent the greater the number of parasites discovered. In the above examinations approximately the same time was spent upon each specimen.

Period of Latency.—It is impossible to state accurately the length of time during which the malarial parasites may be present in an individual's blood without producing symptoms, on account of losing sight of the cases before such determination can be made. It may be broadly stated, however, that in some cases the malarial parasites may be present for almost an indefinite length of time without producing the characteristic symptoms of malarial fever. In the few cases in which I have been able to make examinations of the blood at frequent intervals, covering a considerable period of time, I have found that this incubation period, as it may be called, may extend from a few days to several weeks. In one case of estivo-autumnal fever, examinations were made of the blood every third or fourth day for a period of six weeks, and almost every examination showed a few hyaline "ring forms" of the parasite. During this period, however, there were never any symptoms which in the least suggested the presence of a malarial infection. At the end of six weeks I lost sight of the patient, but it is probable that the infection existed for a much longer time without producing symptoms. As a rule, the patients in whom the blood showed the presence of the malarial parasites included in this report developed symptoms within a week after the observation, and some of them in a much shorter time, although several went for two weeks without symptoms.

It is easily conceivable how a weak malarial infection—that is, one in which there are but few malarial parasites present—might exist for a long time without the production of symptoms, due to the small amount of malarial poison present in the body. From a study of the above table it will be seen that by far the largest percentage of my cases are to be placed in this category. The parasites, as a rule, did not number more than eight or ten in a specimen of blood observed for half an hour.

In cases, however, where the parasites were numerous, it was much more difficult to account for the absence of clinical symptoms. There is no experimental data at hand to explain these cases. The most that we can say is that the individual infected is probably immune, to a certain degree, to the malarial poison.

CLINICAL DIAGNOSIS OF CASES.

The following table gives the clinical diagnosis made before the blood of the patients was submitted for examination:

	NO. CASES.	LATENT.	MASKED.
Chronic dysentery	55	0	55
Chronic diarrhœa	19	19	0
Pulmonary tuberculosis	14	0	14
Fractures and wounds	9	9	0
Chronic gastritis	5	5	0
Amœbic dysentery	4	0	4
Acute bronchitis and pharyngitis	3	0	3
Hernia	3	3	0
Chronic indigestion	2	0	2
Anæmia	2	0	2
Secondary syphilis	2	2	0
Otitis media	2	2	0
Acute melancholia	2	2	0
Insanity	2	2	0
Rheumatism	2	0	2
Paralysis	2	2	0
Abscess of the liver	1	0	1
Arthritis	1	0	1
Conval. from appendicitis op	1	1	0
Arthritis deformans	1	1	0
Furunculosis	1	0	1
Retinitis	1	1	0
Varicocele	1	1	0
Tachycardia	1	1	0
Cellulitis	1	0	1
Measles	1	0	1
Pneumonia	1	0	1
Chancroid	1	0	1
Acute constipation	1	0	1
Hemorrhoids	1	1	0
Adenitis, cervical	1	1	0
Diagnosis, undetermined	52	52	0

From a consideration of this table it will be seen that by far the greatest percentage of cases of masked and latent malaria occurred in patients suffering from diseases of the alimentary tract, especially dysentery and diarrhœa. Next in frequency comes the diagnosis of pulmonary tuberculosis.

In classifying these cases into latent and masked infections, as I have before noted, it is sometimes almost impossible absolutely to determine which variety of infection really existed. Some of the cases, from a study of the clinical charts, show a preponderance of symptoms in favor of the diagnosis made, and in these cases it is easy to class the malarial infection as "masked." In the study of many other clinical histories, the entire absence of any symptoms which could be attributed to malaria make it easy to decide that the malarial element was "latent;" but there occur a considerable number of cases in which the symptoms were so confusing that the distinction could not be made.

Classified as nearly as possible in this manner the 155 cases were divided as follows:

Masked infections	40
Latent infections	115

Chronic dysentery: Fifty-five cases in which the diagnosis of chronic dysentery was made showed the presence of malarial parasites in the blood, the type of parasite being the estivo-autumnal in forty-five cases and the benign tertian in ten cases. In all cases in which the diagnosis of "chronic dysentery" was made, it was found by a study of the clinical charts that the dysentery existed and evidently masked the malarial complications. All the cases were having numerous bowel movements, and all showed slight rises in temperature at irregular intervals. These rises in temperature are characteristic of dysentery, and a study of the temperature charts proves that the existence of the malarial infection could not have been determined by the temperature curve. There probably occurred among the dysentery cases a small number in which the malarial infection was latent, but in the great majority of cases there were symptoms present which, taken alone, would have suggested malaria; but taken with those which are present in dysentery, completely obscured the malarial condition. I have, therefore, classed all the cases of malaria occurring in chronic dysentery as masked infections.

The occurrence of "masked malaria" in cases of dysentery originating in the Tropics is a matter of great importance, as the malarial element in so large a proportion of the cases is not recognized, and undoubtedly helps in producing the marked debility of the patient, which is invariably present in dysentery cases. In a large number of cases showing the malarial parasite, treatment by quinine caused a marked improvement in the number of bowel movements, and in several cases it must be confessed that the dysenteric symptoms were directly due to the malarial infection, as they quickly succumbed to quinine. Almost all of the dysenteric cases gave histories of previous malarial infection in the Philippines, the primary infections being diagnosed and treated. The treatment, however, was not continued, and there resulted a chronic malarial infection, presenting few typical symptoms, but which aided in the depletion of the patient's strength and vitality. The treatment of these cases with quinine invariably resulted in benefit.

Chronic diarrhœa: In nineteen cases diagnosed as chronic diarrhœa malarial parasites were demonstrated, and in all these cases the infection was latent. Symptoms of diarrhœa were present in all, but there was no rise of temperature, and no symptoms which could be interpreted as being malarial in character. Treatment by quinine in these cases quickly caused the disappearance of the parasites from the blood, and, as a rule, resulted in the general betterment of the patient's condition, so that, while the cases have to be classed as latent, on account of the absence of symptoms, the improvement in the patient indicates that the malarial infection had some influence in the progress of the diarrhœa.

Pulmonary tuberculosis: Fourteen cases diagnosed as pulmonary tuberculosis showed the presence of malarial parasites, ten cases being due to infection with the estivo-autumnal parasites and four with the benign tertian. From a study of the clinical histories and temperature charts in these cases, the infection in every case was masked by symptoms which suggested pulmonary disease. Perhaps in no class of cases is the diagnosis of pulmonary tuberculosis made so often as in cases of malaria showing quotidian elevations of temperature. Such cases are often accompanied by a cough, great emaciation, profuse perspiration, and present the picture of pulmonary tuberculosis. This is especially true of cases originating in the Tropics, the emaciation in these cases being more extreme and the pulmonary symptoms more apparent than in cases originating in the temperate zone. In all of the cases diagnosed as pulmonary tuberculosis the parasites were present in considerable numbers, and treatment by quinine showed in a few days that the infection was purely malarial. The examination of the sputum in these cases for the tubercle bacillus always resulted negatively.

Fractures and Wounds: In all cases diagnosed as fractures and wounds the conditions diagnosed were present, the malarial infection being latent.

Chronic gastritis: Five cases diagnosed as chronic gastritis showed the presence of malarial parasites in the blood, and in all these cases the malarial infection was latent, as shown by the fact that treatment with quinine did not relieve the condition diagnosed. In all the cases chronic gastritis was present, and in all of them a history of previous malarial infection was obtained.

Amœbic dysentery: The four cases diagnosed as amœbic dysentery were severe forms of that disease, numerous amœba being present in the fæces. The malarial infections, so far as any symptoms shown by the clinical histories, were masked. The occurrence simultaneously of the malarial parasite and the amœba, both protozoan organisms, is of interest. Treatment by quinine of these cases resulted in benefit. But, as cases of amœbic dysentery are also benefited by quinine, it is impossible to say how much actual benefit was derived from the elimination of the malarial element. It is a fact, however, that all of these cases improved much faster after the treatment for malarial infection than they had previously.

Acute bronchitis and pharyngitis: In the three cases diagnosed "acute bronchitis and pharyngitis," the malarial infection was masked. All three cases were infected with the estivo-autumnal parasites, and the symptoms present were those of bronchitis and pharyngitis. Treatment with quinine in these cases eliminated the malarial element and also the bronchitis, but did not improve the pharyngitis; so that it is safe to say that the bronchitis present was due to the malarial infection, the pharyngitis occurring as a complication.

Abscess of the liver: The case diagnosed as "abscess of the liver" presented, from a study of the clinical history and the temperature charts, all the symptoms which are said to be classical in this disease. The man gave a history of having suffered from amœbic dysentery in the Philippines, but on arrival at the hospital presented no evidence of dysentery. Examination of the blood showed numerous estivo-autumnal parasites of the tertian variety, and treatment with quinine resulted in the disappearance of all the symptoms.

Other diseases: In the two cases diagnosed as "indigestion" the infection was "masked;" in the two diagnosed as "anæmia" the infection was also masked by profound anæmia, which was at first supposed to be pernicious; in the case diagnosed "arthritis" the infection was masked by this disease. This was also true of the cases diagnosed furunculosis, rheumatism, cellulitis, measles, pneumonia, chancroid, and acute constipation. In the cases diagnosed as hernia, secondary syphilis, otitis media, acute melancholia, insanity, arthritis deformans, retinitis, varicocele, tachycardia, paralysis, hemorrhoids, and cervical adenitis the malarial infection was latent.

there being absolutely no symptoms pointing to such infection.

Undetermined diagnosis: In the fifty-two cases in which no diagnosis was made previous to an examination of the blood, the malarial infection was "latent." In most of these cases quinine was immediately given, so that it has been impossible to ascertain how long the infection would have persisted without producing some symptoms. In none of the cases was there any suspicion of malaria, as a careful investigation of the clinical histories and temperature charts demonstrates.

Most of the cases were soldiers who had returned from the Philippines, having suffered there from long-continued dysentery or diarrhœa, and were returned to this country because of their debilitated condition. Active symptoms of the diseases from which they had suffered in the Philippines were not present in any of these cases, the chief symptoms complained of being general weakness, which prevented them from doing the duties of a soldier. I have taken considerable care to inquire into the medical history of these cases, in order to find out, if possible, whether or not the infections were masked by existing symptoms or were actually latent, and in every case, from the history obtainable and the present condition of the patient, the infection would have to be classed as latent. Most of the cases gave a history of having suffered from malarial attacks either in Cuba or in the Philippines, but considered themselves as rid of malarial infection.

Source of Infection.—In the 195 cases of masked and latent malaria the source of infection has been traced in 180. Of the 180 cases, 120 suffered from their first attack of malaria in the Philippine Islands, while sixty gave a history of having had their first attack in Cuba.

Of the sixty Cuban infections, it was found upon inquiry that these infections occurred during the American invasion at Santiago, and had persisted irregularly up to the present time.

In the case of the Philippine infections, the time during which the patients had suffered from malaria varied from six months to two years.

The history of all the cases showed exacerbations of the malaria at irregular intervals following the primary attack, but all of them gave a history of not having had an attack for at least one month before arrival at this hospital.

During the fifteen months in which I have kept records of masked and latent malarial cases there have been a few instances, especially in the cases which were latent, in which no previous history of malaria could be obtained. Most of these cases had been in camp at the Presidio, California, for some weeks. They had never suffered from malaria either in Cuba or in the Philippines, so that I have been compelled to consider San Francisco as the locality in which these patients became infected. Up to within a comparatively recent period, San Francisco has not been considered as a malarial region, and it has been denied by competent investigators that the estivo-autumnal type of malaria ever originated in San Francisco or the country immediately surrounding it. From my observations in the cases just spoken of, I am satisfied that cases of estivo-autumnal fever do occur, and have probably been imported by infected individuals returning from the Philippine Islands. As stated in the opening paragraphs of this report, all that is necessary to establish a malarial infection in any locality is an infected individual and mosquitos of the genus *Anopheles*. I have repeatedly found mosquitos of this genus in the military reservation at San Francisco, and it can easily be seen how, with the large number of infected soldiers returning from the Philippines, malaria may become endemic in this locality. The following case of estivo-autumnal fever is of interest in this connection:

The patient, a young girl, was referred to me for a blood examination by the physician attending her. She had been suffering for some time from slight fever, accompanied by chilly sensations at irregular intervals, and by marked anæmia. She had never suffered from malaria previously, and had not been out of San Francisco within a period of two years. The attending physician suspected malaria, and the blood examination showed numerous "ring forms" and pigmented forms of the tertian estivo-autumnal parasite. Upon careful inquiry as to the source of her infection, the following facts were elicited:

Patient lived in a locality situated between two Chinese vegetable gardens. The water used for irrigation is obtained from sunken wells, which are open and filled with stagnant water. The mother of the girl stated that the people living in this locality were greatly troubled by mosquitos; and upon inquiry of people living in the vicinity, I was told that mosquitos were plentiful and very annoying. I also learned that numerous cases of malaria had occurred in this locality. This case proves conclusively that estivo-autumnal malaria may originate in this city, and also shows how important it is to trace out the source of infection in malarial cases. By the careful use of kerosene in the wells, which are evidently the source of the mosquitos, it is not too much to believe that malarial fever may be entirely eradicated in the locality spoken of.

Post-mortem Findings in Latent and Masked Malaria.—Of the 195 cases of latent and masked malaria, five proved fatal from the diseases which complicated them. Three cases of masked malaria died from chronic dysentery, as well as two cases in which the infection was latent. All of the cases showed estivo-autumnal parasites in the blood.

In a future communication I shall give in detail the gross and microscopical pathology of these cases, at the present time only touching upon the conditions found.

In the cases of masked malaria, the liver, spleen, and brain showed marked pigmentation, and upon microscopical examination showed all the conditions of malarial infection. The capillaries of the brain contained numerous estivo-autumnal parasites, much pigment, and numerous pigmented leucocytes. This was also true of the capillaries of the liver. Sections of the spleen showed large numbers of hyaline and young pigmented forms of the estivo-autumnal parasites, a few crescents, many pigmented leucocytes and an immense amount of free pigment.

In the two cases in which the malarial infection was latent, the chief pathological changes were found in the spleen and liver. Both organs were much pigmented, the spleen being considerably enlarged. Sections of the liver showed considerable free pigment within the capillaries, but no malarial parasites. Sections of the spleen showed an immense amount of pigment, numerous pigmented leucocytes, and comparatively few hyaline and pigmented parasites. No crescents were observed in the sections of the spleen. The condition of the sections of the spleen, as compared with those in which the malarial infection was masked, seemed to be one simply of degree, the masked infections showing a much greater pigmentation and many more parasites than the latent infections.

These cases, especially those which were latent, are of great interest, as the pathological conditions found prove that the evolution of the malarial parasite may go on [illegible] the spleen and other internal organs without the production of definite clinical symptoms.

Conclusion.—From the brief analysis which I have given of these cases of latent and marked malarial fever it will be seen at once how important an examination of the blood is in all cases of disease originating in the Tropics, or in localities which are known to be malarious. It is an undoubted fact that a malarial infection complicating any disease process invariably injures the patient's chances of recovery and its elimination, as proven by numerous cases observed at this hospital, greatly facilitates recovery. Not only is this so, but cases have been observed in which the discovery of the malarial infection undoubtedly saved the patient's life. The discovery of the cases of estivo-autumnal malaria is especially important, as it is this form of the disease that may become at any time pernicious, and may cause death within a few hours.

I cannot urge too strongly upon the profession the immense importance of a knowledge of malaria sufficient for an accurate microscopical examination of the blood. If by such examination only one life is saved, it will more than compensate for the expense and labor involved in becoming familiar with the appearance of the various forms of malarial parasites in the blood and the proper use of the microscope.

AUTOINTOXICATION AND DISEASE FROM A PRACTITIONER'S STANDPOINT.*

By BEVERLEY ROBINSON, M.D.,

NEW YORK.

Autointoxication of neurotic origin is not considered at the present time to be usual, if we are to be strictly guided by the tenor of the medical press. That of gastrointestinal origin is alluded to quite frequently and dwelt upon at times, and very properly, as being of great pathological importance in many directions.

No one probably more than Professor Bouchard of Paris has thrown light upon the various obscure problems involved in this subject. Even now, despite the researches of numerous careful investigators, the matter is acknowledged to be a many-sided one, and many questions regarding it are still *sub judice*. One thing is pretty surely affirmed, however, and it is that depression of the general nervous system—a marked undertone—is essential to the development of many and various diseases. Does the nervous system play a primary rôle in causation? About this there is no absolute answer. At times it does unquestionably; again, it is evident that the response from the nervous system is only what we should expect where the entire organism and all its functions are implicated to a slight or considerable degree. The usual view, with respect of autointoxication is, that the toxins present are either developed in the economy or come from the outside. Among the latter causes of disease, syphilis and alcohol, notably, rank easily first. Among the former we find acute miliary tuberculosis at times, and where it is obviously occasioned directly by pus absorbed from degenerated glands or a similar focus situated elsewhere. Very frequently, the autointoxication comes from the gastrointestinal tract including the mouth, as witness certain cases of pernicious anæmia, and produces well-known forms of nervous derangement, organic or functional, viz., general paralysis, epilepsy, melancholia, neurasthenia, etc.

The specialist in nervous diseases and the general practitioner have different standpoints, each being correct in his interpretation, according to the case in hand. For example, the former recognizes different causes of neurasthenia, but to-day is disposed to emphasize rather too much, as I believe, intestinal autointoxication, and medicate in part, at least, with drugs in such form as to be only soluble in the intestine and not at all in the stomach. This to me is a contracted view, and in so far is erroneous. I do not find, nor do I believe in, the presence of changes in a limited portion of the digestive tract, as separated from the rest. Drugs must, above all, be in solution to be useful, and they must affect the stomach favorably, and not solely the intestine.

I have tried successively the numerous intestinal antiseptics uncombined, and in various mixtures, and I have concluded that we have none equal to beechwood creosote in small doses, combined with essence of pepsin and properly diluted with water, or alcohol and water. Of course, the specialists use other means than mere antiseptic medication to restore their patients. The liberal input of water, massage, rest, good diet, hydrotherapy, electricity, systemic exercises, are all mentioned, and sometimes insisted upon. On the other hand, the general practitioner believes too much stress is laid upon gastrointestinal fermentations as directly and primarily causative.

Here is only an element, not an entirety. The real thing is "wear and tear" of modern life, and especially in men and women near or past middle life. Anæmia, menstrual irregularities, late hours, faulty education, particularly in young girls near puberty, are mainly responsible for many physical breakdowns of the sort I am studying. With the boys at the same age, overwork at school or college, dissipations, improper food, etc., work out their own wretched physical infirmities.

The chemist tells us that in many such cases he finds an excess of indican in the urine, or other by-products, in the intestine, of faulty proteid malassimilation. To this indicanuria or indol, in a less advanced form, too much importance may easily be attached. Unless it be quite constantly present and in excess, it has no great prognostic significance, and its precise poisonous quality is not accurately known. Gout, rheumatism, diabetes, no doubt, result in great part from faulty metabolism, and when they are established, it is not long before the nervous system becomes affected functionally or organically. A lowered tone of the nervous system renders the economy an easier prey to microbic infection, which, if the body were in a healthy state, would not take hold and produce diseases of different sorts.

The great sympathetic nerve is oftentimes finally affected, and is the near cause probably of many dynamic disturbances; *i.e.*, flushings of face, passing erythemas, etc. We recognize this notably with women at the menopause. At this period, we have also cases of gastrointestinal disturbance with physical signs of dilatation, or even a pronounced gastroptosis and enteroptosis.

A vicious circle is now formed, and on the one hand we have the gastrointestinal tract as a cause of intoxication of the nervous system, and on the other hand we find a depressed state of the nerves, which also tends to produce autointoxication, especially if, as it frequently does, it localizes its action in the stomach or intestines. From any point of view, the latter condition, if admitted, makes the economy more receptive to morbid effects of microbic infection, and brings on rapidly a pressing state of pathological, omnipresent imminence for both stomach and bowels, and indeed all organs.

How should one treat such cases? First, and above all, use proper saline purgatives to wash out intestines. Then make a judicious and well-ordered appeal to the proper intestinal antiseptics that are in solution, and will not effect stomachal revolt. These antiseptics seem to neutralize or destroy, at least for a while, all injurious by-products of defective digestion. What these products are precisely it is most difficult, at least practically and clinically, to state positively. In the same way, it is equally difficult to say which are the really poisonous products. Too many instances of sudden and fatal poisonings at church festivals and wedding feasts prove this, where later no pathological lesions of definite value could be found, and where unknown "ptomains" were the sole explanation afforded by the most careful inquiry and research on the part of our best skilled observers. Finally, the general nervous system must be toned up with iron, arsenic, strychnine, iodide of potassium, especially if syphilis is present, or arterial tension is exaggerated. In this manner the progress of degeneration of the nervous system may be arrested occasionally, and that already produced may be favorably influenced, as numerous instances demonstrate. The disappearance of passing symptoms in tabes dorsalis, *i. e.*, the squint, the fulminant and girdle pains, the Argyll Robertson pupil, gives evidence of it indisputably. In rheumatism, I have seen one notable case of ocular paralysis, wrongly referred to syphilis, and seemingly permanent for many months, thus cured. It is also shown, as I believe, that the careful, wise clinician should always think seriously of, and examine carefully for, gastrointoxication in nervous diseases, even though local pain and other apparent symptoms of impaired digestion are not readily discovered. This statement is particularly emphatic with respect to cases in which alcohol and syphilis and metallic poisons as causes cannot be found.

---

*Read before the New York Clinical Society.

I would add that while autointoxication from the stomach and intestines as a source of disease presents numerous difficult and obscure clinical data, it is nevertheless far more satisfactory and certainly truer in etiology of morbid changes than to repose in the idle assumption, as formerly, of cold, fright, exposure, over-fatigue, as efficient and direct causes of nervous affections.

It has been claimed by some writers lately (Chapin, *Postgraduate Magazine*, September, 1901, editorial, *Medical News*, September 29, 1901) that, despite frequent laudation by numerous physicians, so-called antisepsis of the intestinal tract through treatment is of questionable value. This is said to be true of adults and children. It is also stated that many antiseptic drugs upset stomachal and intestinal digestion, and are direct irritants of the mucous membrane lining these organs. Again, it is stated that whatever inhibitory action may be exercised by them over the development and power for harm of certain bacteria, this inhibition is exercised even more upon the healthful action of the viscera affected. and this is greatly to be deplored. After all, they say we can only hope to attain really useful results through restoration of normal nutrition, and other means, therefore, should be employed in preference to drugs which interfere with this desired object. I am disposed to recognize the force of this argument about several drugs which I have tried and found wanting.

There are three, fortunately, which my personal experience would support with unqualified praise in numerous cases. The first, already mentioned, is creosote, properly combined and in minute, repeated doses; the second is wood charcoal, and the third, the subnitrate, and perhaps other salts of bismuth.

In certain instances, especially those where lowered nerve tone of different origin is primarily causative, I obtain frequently better curative effects from the use of the mineral acids than I do from any so-called antiseptic drugs. I have found dilute phosphoric acid particularly useful, and believe it may be properly combined with one of the simple vegetable bitters as quassia, calumba, or gentian.

Besides checking intestinal fermentation and decomposition directly, in many instances phosphoric acid is a tonic and a useful one to the nervous system, and without apparently detrimental effects upon the kidneys, although continued in moderate doses for a long while.

In patients who are languid, depressed, introspective, almost melancholic at times, I have seen a moderate temporary course of static electricity to be highly beneficial. Where, as I sometimes find, manifestations of rheumatism, due to autointoxication, hang around a patient and defy seemingly rational drug treatment, faradism applied through water, as we have it given in the electrical bath, is curative in great degree. Those who have a torpid, engorged liver. due to alcohol or over-eating, are the patients who derive most benefit, and without being invidious, I would call attention to not a few of our stockbrokers *et id omne genus.*

I do not believe that any amount of flushing the intestine is very valuable, unless a suitable purgative be employed in the beginning of treatment of toxæmia of intestinal origin; and when the bowels have been thoroughly evacuated, I rely more upon the drugs just mentioned than I do upon repeated flushing of the colon. Occasionally, without doubt, and particularly in those instances where the large intestine is the great and immediate source of trouble, the use of Kemp's tubes, or the ordinary funnel and long-rubber tube, as for stomachal lavage, may be signally valuable. But these are the exceptional cases at best, and we should not be misled to make use of irrigation of the bowel and abandon the other means upon which, as a rule, the well being of the patient, in greater measure, depends. Of course, I do not wish to decry intestinal irrigation; but I do wish to give it a proper place in therapeusis, and not, as now, exaggerate its importance through undue praise, because of its being somewhat of a novelty. This opinion, I know, is at variance with that of a distinguished foreign observer (Boas), who holds that intestinal lavage is only second in great importance to purgation. For several writers to-day favor the use of antiseptic drugs, by lavage of the bowel, rather than through the mouth, and they go so far as to affirm that no results of any permanent value are obtainable by the administration of antiseptic drugs after this manner.

To my mind, as I have stated, this is a far too radical statement, and while I recognize the importance of opposing in a measure the perhaps too positive statements of Bouchard and Beaumetz, I would not abandon what is true clinically: and that is, that many fermentative intestinal disorders are helped obviously by taking drugs through the mouth. None of these methods, however—purgation, the use of intestinal antiseptics through the mouth, lavage of the large bowel with sterilized water, or deci-normal salt solution sterilized, electricity—are complete in their good effects unless frequent judicious massage is employed. No doubt, muscular power is thus evolved, and in consequence increased motility of stomach and bowels is obtained. While the use of purgative remedies should only be occasional, if we are to anticipate the most favorable effects, proper massage may be employed once or even twice daily for long periods of time with great success, as I have repeatedly observed.

The question which now arises is in regard to foodstuffs, their proper most judicious selection, and the evil effects which may result from their fermentation or decomposition. Finally, the questions, What are the injurious products which are absorbed, and when are among the most difficult problems for solution. I have learned to hold in reasonable doubt many of the affirmations of a latter day truth, which would interdict absolutely certain foods on account of supposed chemical reactions, and have returned in many instances to the older though empirical control which specially observation of each individual digestive capability affords. I am confident also that the capability of digesting certain foods without reasonable explanation, so far as clinical observation goes, shows that the digestive power changes from time to time for certain articles of diet at least in a given system. What is true of food is also true of drink, and I have known of more than one patient who discovered to his cost at a certain time that such a water, wine or spirit had become positively injurious, whereas previously he had drunk of it with impunity.

The subject of auto-intoxication and nervous depression, with its frequent mechanical sequelæ, as dilatation of stomach, bowels, and other abdominal viscera, is not merely of medical interest. There is a surgical side and a very important one. If gastroptosis, enteroptosis, dilated stomach, displaced liver, kidneys, uterus are only the result, and in numerous instances they are, of previous malnutrition, bad habits, unhealthful surroundings, hereditary taints; and if, after careful inquiry and consideration, such conditions cannot be corrected, or at least there is no reasonable hope of this correction, why operate upon such cases? I doubt not that many hospital operations—not to speak of those in private practice—are successful so far as the operations are concerned, but when we come to look into the later condition of such patients, the question arises, are they permanently benefited? In my limited experience, I should say, no. I should be willing to affirm, with what data I possess, that the knife is of more than doubtful value. The way, of course, to settle this question, like many others, is to follow up such cases closely after operation for many months, or even years, and thus to find out and determine accurately what measure of temporary or permanent benefit has resulted. I am told by one distinguished surgeon that the after-date of many surgical operations is sadly deficient with us, and we are obliged to recur to foreign statistics, especially the German, to furnish us with a basis of honest solid conviction. Why this is, I am not altogether prepared to affirm. I suspect, however, it is mainly due (1) To the fact that its importance has not been sufficiently recognized; (2) Because it is very difficult to follow up patients closely after they leave the hospital and obtain from them full and reliable personal data, (3) The number of private cases of a particular operation by any one surgeon are usually too few to permit of more than a kind of individual impression, rather than settled belief, as regards an ultimate conclusion.*

This interesting and important topic might be greatly enlarged upon. Its elaboration I prefer to leave in your hands. At best, I have been and can be only suggestive. For my little effort I crave your indulgence.

*Fortunately, since writing this paper, a distinguished American physician (Dr. R. H. Fitz of Boston) has supplied, in part, the deficiency referred to (*Medical News*, page 1009, December 28, 1901). In my judgment, every practitioner would do well to read this valuable and timely contribution.

Dr. Leonidas H. Laidley has been appointed Medical Director of the Louisiana Purchase Exposition, or World's Fair, to be held in St. Louis in 1903. Dr. Laidley is a graduate of the Jefferson Medical College of 1868, and the Bellevue Hospital Medical College of 1872, and has practised in St. Louis for the past thirty years.

DIABETES MELLITUS—ETIOLOGY AND PATHOGENESIS.*

By CHARLES E. NAMMACK, M.D.,
NEW YORK.

PROFESSOR OF CLINICAL MEDICINE, CORNELL UNIVERSITY MEDICAL COLLEGE; VISITING PHYSICIAN TO ST. VINCENT'S HOSPITAL; ATTENDING PHYSICIAN FOR OUTPATIENTS, NEW YORK HOSPITAL.

The presence of sugar in the urine does not necessarily indicate diabetes mellitus. Sugar may appear in the urine, usually in small quantity and temporarily, from many transitory causes. In fact, certain authorities claim that in urine concentrated by evaporation, faint reactions of sugar may be obtained from perfectly healthy individuals. But for practical everyday work, we may assume that healthy urine is free from sugar, and when the ordinary copper tests persistently and repeatedly show the presence of sugar, we must assume that diabetes mellitus exists. Robert Saundby[1] has seen only sixty-nine specimens of non-diabetic urine which reduced copper, and in eleven cases the reduction was not due to sugar. Any change, even from blue to green, demands further investigation of the case, especially by filtering the urine repeatedly through animal charcoal, which removes all reducing substances except sugar and accentuates the sugar reaction. Alimentary or physiological glycosuria exists in certain individuals after the ingestion of an unusual quantity of sugar. At times, lactosuria occurs in pregnant and nursing females because milk sugar is formed in the breasts in excess, and reabsorbed into the circulation. In these cases of alimentary glycosuria, it is important to consider whether the condition is a precursor of diabetes mellitus. J. Strauss[2] would answer this question in the negative, but it is a matter for careful individual decision.

Toxic glycosuria may be set up by the ingestion of many substances other than sugar itself. Alcohol causes glycosuria in many cases, not only by inducing disorder of the liver and of the nervous system, but by the effect of the alcohol itself. The combination of chronic gastritis, chronic alcoholism, and chronic hepatitis furnishes by far the largest number of cases of non-diabetic glycosuria. Remedial agents which are stated to produce sugar in the urine are ether by inhalation, amyl nitrite, mercury, hydrocyanic acid,[3] sulphuric acid, alcohol, strychnine, glycerin, nitrobenzol, and others.

Pathological and traumatic glycosurias are met with in injuries, derangements, or diseases of the nervous system. Portal thrombosis, acute yellow atrophy, and perhaps phosphorus poisoning will set up glycosuria. Depression of sugar assimilation occurs in hepatic fibrosis, in certain obese individuals, at times in digestive derangements, rarely in diseases of heart and lungs, and sometimes in the aged. When this function of sugar assimilation is depressed, the sugar taken as food appears temporarily in the urine. Many of the infectious diseases are attended with, or followed by, glycosuria. Diabetes insipidus, interstitial nephritis, gout, and early syphilis may have temporary glycosuria as an epiphenomenon.

The majority of these cases of transient glycosuria present no other symptom than the presence of sugar in the urine, and must be carefully distinguished from true diabetes mellitus. The one is merely a perversion of function, readily yielding to treatment, and not accompanied by severe symptoms. The other is a disease, the severer forms of which are incurable, and the symptoms thereof distressing. Cases vary so much that an exact definition of the disease is difficult. F. W. Pavy[4] would differentiate cases of diabetes into two classes, alimentary and compos-

*Read before the New York State Medical Association, New York County, January 20, 1902.

ite. In alimentary diabetes, the essential condition consists in a faulty power of assimilation within the system of the carbohydrates taken with the food, giving the abnormal presence of dextrose in the urine, but not the color reaction with ferric chloride. In composite diabetes, we have not only defective carbohydrate assimilation, but also abnormal tissue disintegration with the production of sugar in association with other abnormal degradation products. These products are represented in the urine by betaoxybutyric acid, diacetic acid, and acetone, indicated by the appearance of a wine-red color on addition of ferric chloride. Under the morbid influence of composite diabetes, the tissues melt down, emaciation develops, and life is often terminated by coma, the result of a true autointoxication. Alimentary may pass into composite diabetes, especially in early life, in neurotic individuals, as a result of hereditary tendencies, and when the individual is under great mental strain.

True diabetes mellitus is a frequent disease in this city, and its frequency would seem to be increasing under the factors of our strenuous life. Among children, school competition; with professional men, keener striving for supremacy in intellectual advancement; with business men, the accumulation of fortunes which would have been considered unattainable by previous generations; with working people, the difficulty of keeping pace with inventive machinery and foreign cheap labor and capitalistic combinations. All these causes are hurrying us on in a mad whirl to premature decay of tissue. Of 202 deaths from diabetes in New York City (Manhattan and The Bronx only) in 1899, fifty-four occurred in Jews and fifty-one in people of Irish nativity or parentage.[5] These figures are striking and suggestive, but my personal experience does not bear out the idea of the compiler, that the cases result from "breeding in and in," but rather that they result from the struggling earnestness of both peoples. Heredity, however, does play an important part in the causation of diabetes, especially in the cases developing in childhood.

Males are affected more frequently than females, in the porportion of 3 to 1, except in the case of children, where, curiously enough, girls are more frequently affected than boys, and the children of the richer class oftener than those of the poor.

Among occupations, those which involve continued and excessive mental application and nervous strain furnish the largest contingent of cases. Muscular activity, without worry, is both preventive and curative of diabetes. Dietary indiscretions, especially when gout or obesity coexists, will produce transient glycosuria and, if persisted in, may lean to permanent diabetes, probably by exhausting the liver by overwork. The excessive use of tobacco may produce the same result[6].

Grief, fright, joy, anger, or anxiety, when intense or protracted, also exert a marked influence.

The relation of lesions of the nervous system to diabetes was first noted by Claude Bernard, and since his time, cases have been reported by many observers, covering a wide range of associated organic and functional nervous diseases, and embracing a voluminous literature. Some authors have gone so far as to claim that all cases of diabetes originate in affections of the nervous system.

The association of insanity with diabetes is so marked as to be more than a mere coincidence. E. C. Spitzka presented a paper before the New York Academy of Medicine on January 20, 1898, showing parental diabetes as an etiological factor in forty-six cases of insanity.[7]

The relations of gout with glycosuria are so intimate that they may be considered as convertible conditions, the symptoms of one often distinctly alternating with those of the other. But gouty glycosuria is more or less persistent, and it should always be borne in mind that it is liable to pass into the graver condition of true diabetes mellitus.

Diabetes occurs more frequently in the obese. It is thought that the obesity masks the diabetes, and that before the obese individual shows sugar in his urine, it has already existed in excess in his blood, and has been converted into fat. In the majority of cases this "lipogenous diabetes," or "diabetogenous obesity," yields to treatment; but in some both the fat and the diabetes persist, while in others the grave form of diabetes, the "composite" diabetes of Pavy,[4] develops, and actual emaciation sets in.

In 1877, Lancereaux called attention to the causative relation between certain cases of diabetes mellitus and lesions of the pancreas. These cases were marked by rapid progress, with loss of strength, great thirst, polyphagia, violent epigastric pain, wasting and loss of sexual desire, with, at first, diurnal, and afterward, also, nocturnal polyuria. Anatomically, atrophy of the pancreas and partial atrophy of the pancreatic duct, with phthisis developing at the apices of both lungs, were found. Death occurred with a low axillary temperature. Hansemann[8, 9] studied the cases in Berlin from this standpoint, and concluded that complete destruction of the pancreas in man may be assumed to cause diabetes mellitus; that destruction of the pancreas does not produce any special form of diabetes, and that pancreatic diabetes has no relation to the sex or age of the individual. On the other hand, extensive lesions of the pancreas have been observed without diabetes, and diabetes occurs without lesion of the pancreas. It has been ascertained, by experiments on animals, that it is not the loss of the pancreatic juice proper upon which depends the production of pancreatic diabetes, because this secretion may be diverted from the intestine through a pancreatic fistula without causing diabetes. It is thought that certain cells in the pancreas secrete a supposititious "something" which is absorbed into the circulation, and which has a glycolytic, or sugar-splitting, property in the blood.[10] The removal of this glycolytic ferment from the blood deprives the tissues of the power to convert glucose into glycogen, or to store it up as fat. This constitutes the pancreas theory of the pathogenesis of diabetes.

Acute diseases, to which diabetes has been considered to be a sequel, are malaria, influenza, measles, and others. The direct causative relation here is open to question. Syphilis has been brought forward as a frequent cause. Diabetes has also been observed in connection with a great variety of other unclassified conditions, but a causal relation in these has not been established.

Notwithstanding the vast amount of work which has been done, the pathogenesis of diabetes mellitus is still unknown. Many theories have been advanced, and each theory has been well supported. The principal theories relate to a perverted glycogenic function in the liver, to perverted metabolism in the tissues generally, to alterations in the pancreas, and to trophic disturbances. The liver theories are two in number. The first supposes that the liver cells are unable to convert the digestive sugars brought to them by the portal vein into glycogen, and that, in consequence, sugar accumulates in the blood. The other theory supposes that the liver cells cannot hold the glycogen after it is formed, but allow it to be transformed too rapidly into sugar, which accumulates in the blood.

The perverted metabolism theory supposes an inability on the part of the muscles, glands, and other glycogen saving banks to appropriate the sugar which is brought to them in the blood

The pancreatic theory has been already alluded to. Since all the processes of metabolism, constructive and destructive, depend upon nerve action, and since experimental, as well as accidental, lesions of the nervous system have been attended with glycosuria, it would seem that some cases of diabetes, at least, may be caused by trophic nervous disturbances. But the evidence, though voluminous, is conflicting and not easy to sift. In fact, it is improbable that all cases of diabetes mellitus depend upon a single cause; and in default of a demonstrable pathogenesis, we must fall back upon a comprehensive definition and say that diabetes mellitus is a disease of nutrition, sometimes acute, generally chronic, characterized by the persistent presence of grape sugar (dextrose) in the urine, by polyuria, and by a progressive loss of flesh and strength. To this we can only add that sugar appears in the urine because it is present to excess in the blood.

The question of the transmission of diabetes from one person to another living in intimate association with the diabetic was raised by R. Schmitz[11] in 1890, but a critical review of 4,389 diabetic patients showed its occurrence in only forty-seven married couples, or 1 07 per cent, a number so small that it seems probable that the occurrence is only accidental.[10]

Although the existence of diabetes is favorable to the development of various microorganisms, none has yet been shown to bear a causal relationship. Phloridzin, a glucoside obtained from the bark of the root of apple and cherry trees, so changes the renal epithelium as to destroy its normal power of keeping back sugar, and to cause it to seize greedily upon the sugar held in solution in the blood.

Phloridzin poisoning, therefore, determines a form of glycosuria which is dependent upon disease of the kidneys. It is possible that there are other poisons, gaining access to the human organism in some manner unknown to us, which may produce similar changes in the kidneys.[12]

Insomnia in Everyday Practice.—David Inglis holds that no treatment of insomnia is likely to be successful which does not recognize the fact that all of our nervous processes are adjusted to periods of alternating activity and repose. Sleep by night presupposes activity by day. It sometimes seems severe to make a man already depressed work like a hired man, but if by doing so he can fall asleep on the spot like a hired man, the result is satisfactory. If work cannot be insisted on, strychnine in the morning, in positively stimulating doses, with a sedative at night may be resorted to. Gout often produces insomnia by the toxic effects of the poison on the protoplasm of the brain elements. In some cases of beginning insomnia, the administration of a soporific to secure prompt sleep for several nights in succession, aided by the wise use of suggestion, will often break up the trouble. For several nights thereafter any inert but bulky powder may be given as a placebo. Increasing the assimilative power of foodstuffs will often overcome insomnia, even in fat women, who in spite of their appearance are often poorly nourished. Fatty foods are the most effectual. Chloral secures sleep more promptly than any other drug, but is dangerous to use. Trional and sulphonal are the safest, and it is well to give the former in small doses at intervals during the day, with a double dose at bedtime. In the insomnia of old age a mixture of paregoric and aromatic spirits of ammonia is often very efficacious.—*The Physician and Surgeon*

Carbolic Acid; Its Use and Abuse.—George W Sargent finds phenol a satisfactory agent for the treatment of indolent ulcer after unhealthy and false tissues have been removed, used in a 95-per cent solution until the surface turns white. Ninety-five per cent alcohol is then applied till the normal color of a clean granulating surface appears. It is serviceable in mammary, tuberculous, and other abscesses, in erysipelas, ivy-poisoning, the lymphangitis that occurs with infected wounds, and the inflammation in caked breast. The danger of poisoning should always be borne in mind. Death has resulted from absorption through the skin. Strong acid on fingers or toes may result in gangrene. If followed by alcohol, there is probably no danger. In poisoning cases, several patients apparently moribund have recovered after the use of alcohol. Whether alcohol acts as an antagonist or as a solvent is not certainly known. In poisoned cases, wash the stomach out with alcohol, then give whiskey hypodermically with the idea of neutralizing the acid in the blood. Other heart stimulants may be required. Alcohol is the most perfect, the most certain, and the most handy antidote to carbolic acid that we possess.—*The Therapeutic Gazette*

The Relative Importance of Disease of the Heart Muscle and the Heart Valves.—Louis Faugères Bishop calls attention to the fact that there is no condition which requires more careful diagnosis than disease of the heart muscle, for it is easy to mistake functional disorder for the symptoms of serious disease. Moreover, the loud murmur may be of little importance compared to the commencing disease of the heart muscle, detected by the slight alteration of rhythm and small variations of force of the heart beat. Dilatation is capable of producing murmurs as marked as endocarditis; when we add to these the so-called hemic murmurs and the anonymous murmurs heard under the clavicle and various other places, it becomes evident that to diagnose a cardiac murmur as due to deformity of valve segments requires careful examination and prolonged observation. Signs of failure of the heart muscle are more grave than the development or existence of leakage of the valves.—*Pediatrics*.

Traumatic Tetanus.—Guido Baccelli holds that antitoxic serum is more of an immunizing agent than it is a curative one. His preference in tetanus is for the carbolic-acid treatment. This acid is analgesic, reduces temperature, and diminishes spinal reflexes, and all three of these actions are called for in tetanus. A patient referred to by the author received in all 106 hypodermic injections (one every three hours), which, beginning with small doses, finally reached 4 centigrams a dose—in all 3 grm. The patient should be warned of the injection, otherwise the slight pricking may bring on a spasm. Phenacetin combined with camphor can be added to the treatment. —*Gazetta Medica di Roma*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, February 15, 1902.

BARBER SHOP HYGIENE.

We must extend our congratulations to the New York Board of Health for taking up seriously the question of how to make the work of the tonsorial artist less dangerous to the health of the community. The subject is by no means a new one, and readers of the Medical Record will recall how long ago the plea for a clean shave and a safe hair cut appeared in its pages, and how the "menace of the barber shop" has from time to time been pointed out, and suggestions made for decreasing the various dangers. Some years ago we advanced the opinion that, while our city was very slow in the matter, and decidedly behind many others in instituting reforms in this direction, when any steps were taken here they would in all likelihood be the more radical and efficacious because we would have the experience of and the mistakes and difficulties encountered by others to guide us in laying out a plan of action.

This quasi-prediction, it is to be hoped, will prove correct.

In the advance guard of the Board's crusade we find a banner inscribed: "Don't use a sponge on the face; don't use a powder-puff; don't use an alum stick; don't use a towel more than once."

These suggestions to the barber it is proposed to post in every shop. They are good so far as they go, and make an entering wedge; but the greatest care becomes necessary in the proper treatment of the brushes, combs, razors, towels, and the operators' hands. It has been pointed out in these pages that subjects of farus, ringworm, and other dangerously contagious diseases receive not alone the usual and ordinary ministrations of the barber, but that in some shops, especially in the down-town, crowded districts, such cases are actually treated by epilation and other measures over long periods of time. The great danger from such a practice need not be dwelt upon.

Impetigo contagiosa is perhaps the commonest disease transferred from one person to another by way of the barber's chair. The great majority of adult males presenting this affection probably contract it in this way.

The matter is simple enough when we consider the extreme contagiousness of the disease; its association with pediculosis capitis, especially in children who often go for a hair cut at the time the scalp begins to itch and break out. The man who is "next" gets the full effect of the germs as, with unwashed hands, the lather is rubbed into his face; for even in the best shops it is rarely one sees the barber wash his hands between customers, and though manicuring may be done on the premises, it is seldom practised by the barber on himself for the customer's good. While there is probably little danger from the blade itself, still the razor, along with all else, should be kept clean. The greatest danger from lues lies in the use of epilating forceps and tweezers in extracting ingrowing hairs, and in rubbing pimples and cuts with the alum stick, which holds upon its surface blood, pus, and germs from a predecessor.

Another great disseminator of germs is the clipper. After use, it is usually wiped and laid away in a drawer, and considered clean, according to the barber's interpretation of the term cleanliness.

The Board has a task before it in the education of the barber, but if, as it is hoped, the public will aid as teachers, much may be accomplished. There are many educated, refined, and cleanly barbers to whom our criticisms do not apply, and these would gladly aid in instituting such general reform measures as they already carry out in their own establishments. The realization, however, would probably be slower than if urged from the outside. Still, the united cooperation of the guild would be highly desirable. They could make a rule among themselves that children with sore heads (which would include farus and ringworm) should be excluded from the shop; that subjects of active syphilis should be advised to learn to shave themselves, or that extraordinary precautions be taken in all suspected cases. They could further agree that it is detrimental to the best interests of their calling that any member should attempt to encroach upon the more learned calling of medicine by treating such scalp diseases as are caused by germs, and most likely to spread disease in their legitimate *clientele*.

Another very important agreement among themselves would be that when a member of the craft is himself sick with a disease in a contagious stage or form, he should absent himself from work. The entire armamentarium should unquestionably be maintained in a safe state of cleanliness, and to this end brushes, clippers, combs, etc., should be boiled or sterilized in some other way. A method which does not injure the instruments can be carried out by placing them for four hours in a closed receptacle, in which forty-five grains of paraform are evaporated by heat for each cubic meter of space.

Many cities have found it practical to maintain barber shops fairly free from danger to the community, and it is sincerely to be hoped that New York is at last in a fair way to follow in their lead.

THE CONTROL OF HEMORRHAGE IN SURGERY OF THE HEAD AND NECK.

The prevention of hemorrhage has always been one of the most important considerations in the surgery of the neck, mouth, and head, and many plans have been suggested by which this may be accomplished more or less completely. In a recent publication, "Problems Relating to Surgical Operations, 1901," Crile of Cleveland has, after a series of experiments upon animals, devised a method which seems to have acted exceedingly well in controlling the blood supply of the parts during extensive operative work in the region under consideration. A number of cases are reported after a description of the experiments which led to the adoption of the procedure. By a specially devised clamp, the flow through both carotids is temporarily shut off, so that the operation may be done in a practically bloodless field, and with proper precautions there have been noted no serious cerebral disturbances. It was found in a number of instances in which animals were examined post mortem after the carotids had been occluded for periods in some instances as long as forty-eight hours, that there were no signs of embolism anywhere in the brain and that the cerebral circulation had been satisfactorily re-established after the removal of the clamps.

In the cases in which closure of the carotids has been practised in the human subject, the tightening of the clamps has been followed by immediate blanching of the head and neck, but the dangers of too sudden a fall in cerebral blood pressure have been obviated by keeping the patient in the Trendelenburg position. This is an important matter, since tying both carotids simultaneously has frequently been followed by symptoms of serious cerebral disturbances. The cases reported by Crile, however, certainly show that with the carotids clamped, there is enough collateral circulation to maintain the functions of the important nerve centers at the base of the brain, especially when advantage is taken of a favorable position of the patient's body, and when atropine is given before the operation to counteract any possible inhibitory vagus action on the heart. Many observations have been recorded which show without doubt that if the blood supply through the common carotids is shut off permanently, cerebral softening of greater or less extent will ensue; but this need apparently not be feared any more, when the closure is for one or two hours, than is gangrene, when the Esmarch bandage is applied to a limb to keep it bloodless during an operation. A number of very extensive operations are reported, in which the control of bleeding has been very perfect, and it seems that we may consider the method as of great value when carried out with proper precautions. When the time comes for the removal of the clamps, the screw should be loosened slowly so as to allow a gradual resumption of flow through the clamped vessels. The form of the clamp is important, and that suggested by Crile seems to possess all the requirements for the safe control of the vessels.

THE NATURE OF HERPES ZOSTER.

VARIOUS theories have been propounded as to the nature and origin of herpes zoster, but according to Van Harlingen (*American Journal of the Medical Sciences*, January, 1902, p. 141), the simplest and most plausible theory of its production considers it as due to a propagated neuritis. By the designation herpes zoster is to be understood a specific infectious, and possibly contagious, exanthem, characterized in its invasion by lassitude, general malaise, chills, elevation of temperature and more or less digestive derangement. In the sequence of these symptoms neuralgic pains develop in the distribution of certain nerves or metameric areas together with enlargement of lymphatic glands. After the lapse of several days the characteristic exanthem makes its appearance and passes through a fixed cycle of development, acme, and decrudescence. The general symptoms, particularly the neuralgic pains, may continue during this period, or they may diminish in severity, usually, however, disappearing with the advent of the eruption. In some instances, particularly in elderly persons, the neuralgia may constitute a persistent feature. Rarely, visceral complications are present, such as paralysis of motor or sensory nerves, and pleural, peritoneal, articular and visceral inflammations. The posterior (sensory) ganglia of the cord and the Gasserian ganglion are the chief seats of the morbid process. From these, inflammation and degeneration may extend along the nerve trunks and fibers. No other lesions have been discovered after death, although it is probable that further investigation will result in tracing the disease in the various membranes and viscera when its presence has been clinically noted. The numerous examinations of the cutaneous lesions and such blood examinations as have been made have not thrown any light upon the nature of the disease. Zosteroid eruptions are not infrequently observed in cases of poisoning by coal-gas, after the ingestion of arsenic, following injuries of nerves, as a result of mental shock or profound emotional disturbances, in association with hysteria and probably also under other conditions. These should, however, be distinguished from true herpes zoster as described in the foregoing.

THE PREVENTION OF OPERATIVE WOUND INFECTION.

IT happens not rarely that in spite of the utmost care on the part of the surgeon with regard to cleanliness of instruments and of hands, as well as in the preparation of the field of operation, and in the successive steps of the operation itself, he is chagrined by the development of infection and suppuration in the wound. Such a result, investigation has shown, is to be explained by the practical impossibility of rendering sterile the skin of both patient and operator. The infecting agents are lodged not alone upon the surface, but also in the cutaneous ducts and glandular structures, so that they cannot be entirely removed by any of the methods in common employ. As a matter of fact, the functional activity of the sudoriferous and sebaceous glands must constantly result in the extrusion of bacteria upon the surface of the skin. In order to overcome this difficulty so far as possible, Mr. Ernest Maylard (*Annals of Surgery*, January, 1902, p. 1) has adopted two procedures—the one applicable to the operator, the other to the patient. The first consists, following the usual ablution, in immersing the hands for from five to ten minutes in water as hot as can be borne. By this means, dilatation of the capillary vessels is brought about with increased secretory activity on the part of the sudoriferous and sebaceous glands. The soddened superficial epithelium, together with secretions, is finally removed by first rubbing one with the other in the water, and then using ordinary soap, and finally rinsing the hands in warm carbolic lotion (1-40), and also repeating this throughout the course of the operation. The second procedure consists, after cleansing in the usual way with soap and water and alcohol and turpentine, or ether if necessary, in anointing the skin freely and widely with 20-per-cent. of mercury oleate in hydrated wool fat, rubbing this in for about ten minutes, and covering the surface with a piece of lint besmeared with the same preparation, the latter being left in place for twelve hours, when the inunction is repeated, and the application is continued for twelve hours more. The lint is removed when the patient is placed upon the operating table, and the superfluous ointment is rubbed off with a piece of sterile gauze. Although chemical examination failed to disclose the presence of mercury in small bits of tissue removed from the wound-edge at operation, bacteriologic investigation showed that the preparation employed possessed bactericidal properties, and that the skin subjected to its action contained fewer bacteria than skin treated by other methods of sterilization. Finally, and of greatest importance, is the fact, that the clinical results of the method fully sustained the theoretic expectations of its usefulness. The simplicity of the procedure, together with its safety and its promise, would seem to commend it to the favorable consideration of surgeons.

Medical Schools to Be Put on a German Basis.

The Germans are credited with leading the world in education, although a patriotic Scotchman would doubtless claim that honor for his own country.

The system of education in Germany is paternal, that is to say, that the schools, including the medical schools, are supported by the government. The professors at the universities receive their salaries from the State, and in addition get a percentage according to the number of their students. This, to some extent, explains Germany's reputation in the medical world.

Such a scheme in its entirety would be impossible in the United States, but one part of it might be adopted with advantage.

Professor Victor Vaughan, dean of the Medical College of Michigan University, is chairman of a committee composed of representatives from the leading schools of the United States to place these schools on what is termed the German basis. That is, to make it possible for a system of credits to be standardized in all these schools, so that a student in any one of them may transfer to any other without loss of standing.

This portion of the German system, if introduced into the United States, would be favorable to a thorough medical education. It would enable students to take courses under the best teachers in the country, and would also act as a stimulus to the professors themselves.

The colleges represented on the committee are as follows: University of Michigan Medical School, Harvard, Pennsylvania, Johns Hopkins, New York College of Physicians and Surgeons, Western Reserve.

Geographical Distribution of Anopheles and Malarial Fever in Upper Palestine.

Mr. John Cropper contributes a paper on this subject to the *Journal of Hygiene* for January.

It appears that malarial fever is most prevalent in Upper Palestine from June to November, reaching its maximum in October. The disease is almost unknown in the elevated villages, but rife in the low-lying and marshy lands.

Mr. Cropper and party used a tent for protection during the day, sleeping always at night in the open, with no other protection than that afforded by mosquito-netting. Water was drunk freely when there seemed to be no danger of surface contamination and with no ill results. None of the party took quinine, and all escaped malarial infection.

The anopheles identified were A. annularis; sub-species, pseudopictus Grassi, so common in Italy; A. Maculipennis, Meigen, and superpictus Grassi.

The frequency of infection among children was observed, agreeing with the observations of Christopher and Stevens in Africa.

In the Khudecrah district, 2,000,000 eucalyptus trees had been planted; but in the opinion of Mr. Cropper, these trees have not done the slightest good, and perhaps only harm.

Natives suffer much less from malaria than the emigrant Jews, and hardly at all from blackwater fever.

The colony of Tantura is now deserted on account of severe malaria and blackwater fever.

With regard to the use of quinine, Mr. Cropper says: "If ever this drug had a good trial among a far from savage people it is in Upper Palestine; to persons ill of blackwater fever, 20 grams in a single day and 129 grams per day for a week have been given, with subsequent recovery.

The following conclusions were reached:

1. That malaria is rife in every part of Upper Palestine, where anopheles represents the majority of the mosquitos present in the native dwellings.

2. Malaria occurs mainly but not entirely among children, and these show definite signs of infection in enlarged spleens and fever.

3. Malaria occurs sporadically, or not at all, in places where an unsuccessful search was made for anopheles.

4. Blackwater fever only occurs in the most malarious districts and chiefly among Europeans.

5. Estivo-autumnal fevers, greatly predominate, though quartan, a few tertian, and mixed infection also occur.

Dissemination of Anopheles by Wind and Ships.

Whether the malaria-bearing mosquito is carried considerable distances by air currents is as yet "non proven." The evidence in support of this view is insufficient to convince.

Dr. G. F. Nuttall and Mr. Arthur Shipley have been contributing to the *Journal of Hygiene* valuable studies of the anopheles mosquito.

In the first number of that journal the modes of dissemination of this species was touched upon, and in the current number the subject is continued.

Howard says that he is incredulous regarding the supposed long flights of mosquitos, since he has had occasion, in many cases, to observe that mosquitos breed close to localities where their breeding places had not been suspected.

Fermi and Lumbao, referring to culicidæ in Sassari, state that the females do not travel far, because they obtain sufficient food from sucking the blood of man and animals.

In Public Health Reports of U. S. Marine Hospital Service, August 9, 1901, two communications are published by members of the service. Dr. P. C. Kalloch writes from the Gulf Quarantine Station "that the captain of the ship *America*, arriving in quarantine July 24, stated that mosquitos came aboard the vessel on the previous night, at a distance of at least ten miles from land, the nearest point being Chandaleur Island. The opinion prevails in this locality that mosquitos are blown by southwest winds from the Louisiana marshes to this island, a distance of ten to twenty miles, and the experience of this summer seems to accord with the opinion. Mosquitos were very few in number until middle of July, when, after several days of southwest winds, the number was vastly increased. At that time there was no other local condition to explain the sudden increase." The second communication is one by Dr. H. C. Cumming, regarding the presence of mosquitos on board the Spanish bark [illegible] which arrived at the South Atlantic Quarantine Station from Rio Janeiro. The master was positive that there were no mosquitoes on board until the twenty-second day, when some were noticed in the water tanks when cleaned. The water had come from Rio Janeiro. The mosquitoes became so numerous on the journey as to constitute a veritable plague. The United States quarantine officer reports: "When the tanks were opened after fumigation, mosquitoes could be scooped up by the hand."

Dr. Nuttall and Mr. Shipley remark that no migratory flights had yet been observed in connection with Anopheles.

Sir Henry Thompson on Diet

Sir Henry Thompson, who is perhaps the best known genito-urinary surgeon in Great Britain, has just published a book on diet. Sir Henry has long held decided views on this matter, as well as being the champion of cremation.

At the age of fifty-two, thirty years ago, he became a total abstainer on account of suffering from dyspepsia and rheumatism, and received great benefit from the pursuance of teetotalism. Five years ago he, as an experiment, drank two or three glasses of claret a day, but, as the dyspeptic symptoms and pains in the joints returned, he has abstained from alcohol ever since.

Sir Henry Thompson declares that after abandoning alcohol entirely the joints lost their stiffness, and ultimately became as supple and mobile as they were in youth, and continue so to this day. More than half our bodily ills, he believes, are due to improper feeding, and holds that the older one gets the less nourishment one needs.

In his opinion, the head of many a family is veritably killed by the mistaken kindness of his wife in stuffing him with delicacies he cannot digest on the plea of keeping up his strength.

The martyr to his wife's solicitude is persuaded to swallow all kinds of patent foods, so nutritious that his gastric juices are unable to do their duty.

The English surgeon is not an absolute vegetarian, but thinks that three-fourths of our food should be vegetable. Such a diet, he contends, renders the brain clearer and more active, inspires wit, and tends to preserve an equable and placid temperament. The person who thus eats wisely but not too well does not make himself obnoxious by snoring in his armchair, as is so often the case with those who fill themselves to repletion with meals and highly flavored foods. Indigestion is unknown to a man who is strictly temperate in diet, and he is in every way best fitted to fight well the battle of life.

Vaccination and Smallpox in London.

The Statistics Committee of the London Metropolitan Asylums Board issued their report a short time ago which must be regarded as a great triumph for vaccination.

The report says that during the first part of the year there were but few cases of smallpox in London. At the end of August, however, the disease appeared in epidemic form in the large parishes of Marylebone and St. Pancras, whence it spread to every one of the thirty-one parishes comprising the Metropolitan Asylums district. The grand total of cases that occurred in 1901, and have already terminated in complete recovery or death, was 1,017. Of these, 247 cases ended fatally, giving a percentage of 24.28 per cent.

These figures are then divided into the vaccinated, doubtful, and unvaccinated classes, and show a remarkable vindication of the good effects of vaccination.

The subdivisions are as follows: Vaccinated cases, 765; deaths, 108; percentage, 14.21. Doubtful cases, 63; deaths, 41; percentage, 65.08. Unvaccinated cases, 191; deaths, 98; percentage, 51.52.

The vaccinated cases undergo a further subdivision into "over twenty years of age" and "under twenty years of age" tables.

It is gathered from these that the mortality among children and young people under twenty was only 1.87 per cent., that among the elders being 17.52 per cent.; of those between thirty-five and forty years of age who had been vaccinated when young the mortality rate was found to be 28.95 per cent.

These latter figures are a strong argument in favor of revaccination.

The report states that "there is diminution in the protective power afforded by primary vaccination after the age of twenty years," and remarks in conclusion that the facts set forth in it confirm the report of the special committee appointed after the outbreak of 1871-72, which strongly advocated revaccination. It is also pointed out that cases, the recovery from which is not yet complete, have not been included in the tables. Their inclusion will ultimately reduce the percentage of fatal terminations.

All statistics bearing upon vaccination and smallpox should be published, as they provide an extremely valuable object lesson to the doubters. Figures are difficult things to deny, and although the anti-vaccinationists have ofttimes proved themselves past masters in juggling with them, and converting them to serve their own purpose, yet sensible persons cannot fail to be influenced by the striking testimony which statistics have given in favor of the benefits of vaccination.

The opponents of vaccination have exhibited misguided but very active zeal in spreading their propaganda; the disciples of Jenner must display no less strenuousness in controverting such biased and prejudiced views.

Smallpox in Spain

Smallpox is still extremely prevalent in many parts of the world, and especially in those places in which the laws regulating vaccination and revaccination are not stringent, and are not strictly enforced.

Germany provides a splendid object lesson in the matter; there, as in no other country, vaccination and revaccination at stated periods is efficiently carried out, the consequence being that smallpox has been almost completely vanquished.

Spain has no enviable reputation as regards her health laws, and an American is apt to associate with Spaniards slipshod and careless methods of preventing disease.

However, if the municipal authorities of all Spanish towns issued as drastic proclamations for the suppression of smallpox as has the alcalde of Valencia, several American cities might with advantage take example from them.

According to United States Marine Hospital Service Public Health Reports, January 24, the city ruler of Valencia has given notice that the following regulations must be complied with:

1. Vaccination and revaccination of all the inhabitants not already vaccinated declared compulsory.

2. To facilitate compliance with this order, without expense or trouble to the inhabitants, all the sanitary posts and relief stations of the city shall be permanently open.

3. All municipal doctors shall make known to the families of the sick poor whom they visit that they

can only assist and supply medicine gratuitously on condition that they get vaccinated within twenty-four hours.

4. All schoolmasters, both of public and private schools, shall require certificates of vaccination from their pupils, and hold the same to be shown to municipal doctors charged with sanitary inspection of schools.

5. Laborers employed by the municipality will not receive wages unless they present medical certificates of vaccination.

6. Directors and owners of factories and workmen of all classes shall exact from all their employees certificates of vaccination under penalty of fine if they admit any one without such certificate.

7. The directors of penitentiaries, hospitals, almshouses, homes for the invalids, asylums, sanatoriums, or similar establishments shall proceed immediately, if they have not done so already, to vaccinate or revaccinate all those under their care, and refuse admittance to visitors not furnished with vaccination certificates.

8. In the shelter sheds and casualty wards for paupers no admission or assistance will be given to the unvaccinated, unless they submit to vaccination on the spot.

9. The charity tickets distributed on feast days by sub-mayors will not be honored unless accompanied by certificates of vaccination.

10. All applications for stalls and booths in public markets must be accompanied by such certificates, or no notice will be taken of them.

11. No name shall be inscribed on the parish poor list of any unvaccinated person.

12. Sub-mayors shall visit and inspect all houses in their respective districts, beginning with those in which cases of smallpox exist, and shall insist upon the immediate vaccination of all those who have not already complied with the order, threatening with summons and fine for disobedience to constituted authorities and endangering public health if they refuse to get vaccinated within twenty-four hours.

13. Proprietors of hotels and lodging houses shall refuse to admit any one without proof of recent vaccination.

The infraction of any of the foregoing articles will be punished with a fine of fifty pesetas.

The preceding regulations appear to cover the entire ground, and to allow no loophole of escape from vaccination. These have been quoted at length to show that so far as enforcing vaccination, Valencia in benighted Spain requires no lesson from any town in lands considered highly enlightened.

AN UNSUCCESSFUL EXPERIMENT.

A dispatch from Appleton, Wis., under date of January 29, tells of the incineration by an infuriated mob of the house of a medical crank who took upon himself the responsibility of proving a new theory.

Under ordinary circumstances mob-violence is to be deplored, and attack upon the property or person of a physician is to be deprecated. In this instance, however, it would seem almost too bad that the "Doctor," unless he can otherwise prove himself insane, was not at home at the time the brand was applied.

If the report be true, this gentleman held pronounced and advanced anti-vaccination views, and to prove that he was right smeared smallpox virus over his hands and started out on a week's trip from town to town to show that the disease is not contagious.

The people now attribute a severe epidemic to his peregrinations with unwashed hands.

News of the Week.

College of Physicians of Philadelphia.—At a stated meeting, held February 5, Dr. David L. Edsall read a paper entitled "A Remarkable Case of Coma, Apparently due to Acid Intoxication sui generis." Dr. F. X. Dercum exhibited "A Case of Adiposis Dolorosa in the Male." Drs. S. Weir Mitchell and Simon Flexner read a paper entitled "A Recent Research on Snake Poisons." Drs. Chas. K. Mills and W. J. Hearn, together with Dr. G. E. Pfahler, read a paper entitled "Brain-Tumor Localized by Clinical Study and Demonstrated by the Röntgen Rays; Partial Removal by Operation; Death with Autopsy." The ocular conditions present in the case were discussed by Dr. G. E. de Schweinitz.

University of Pennsylvania.—Dr. George E. de Schweinitz has been elected professor of ophthalmology in succession to the late Dr. Wm. Fisher Norris.

Typhoid Fever Still Increasing in Philadelphia.—Despite the expenditure of large sums of money for the construction of filtering plants and the provision of subsiding basins, the work progresses but slowly. Contracts are awarded to favored contractors, notwithstanding that their bids are not always the lowest, and often are the highest, so that it has become necessary to ask for more money in addition to that which has already been appropriated, and which at the time was said to be ample. Meanwhile taxpayers are sickening and dying in increased number from typhoid fever, while high officials and leading politicians are becoming opulent through division of the blood money. According to the report of the Health Officer, 254 cases of typhoid fever were reported to the Bureau of Health for the week ended February 8, and thirteen deaths from the same cause.

To municipal inefficiency must be charged also the persistent increase in the number of cases of smallpox, of which 100 were reported for the week ended February 8, together with twenty deaths from this cause. The number of cases of diphtheria and of scarlet fever is smaller, being 68 and 50, respectively, with fourteen deaths from the one and five deaths from the other.

Other conspicuous causes of death were pneumonia, 115; pulmonary tuberculosis, 72; nephritis, 49; heart disease, 34.

To Prevent the Spread of Smallpox.—The Philadelphia Board of Health has decided to supply milk dealers, who serve milk to houses in which smallpox exists, with quart and pint tin cans, distinguished by a yellow ring. The quarantine officer at each house will receive the can from the milkman, and empty its contents into a pitcher belonging to the quarantined family.

Professor Virchow, who had a painful fall some weeks ago, is reported to be improving slowly, being now able to pass several hours each day in an armchair. In the latest number of *Virchow's Archiv* is an address by the editor expressing to all his friends throughout the world his thanks, which it would be impossible to extend individually, for their congratulations and good wishes in celebrating his eightieth birthday, on October 13, 1901. On that occasion he received eight hundred telegrams, and many more letters and gifts, from all parts of the world. He gives a list of all these messages from individuals, societies, cities, and governments, and dwells upon the pleasure they gave him and the gratitude he feels. He had at first deprecated any such celebration, but had to yield to the insistence of his friends, and, of course, has now no regrets for having done so. The theme of felicitation was too spontaneous and too great to afford anything but the most heartfelt and grateful pleasure to the one so honored.

The East Orange, N. J., Smallpox Hospital.—Vice Chancellor Emery on Saturday last refused to grant an injunction to restrain the East Orange authorities from maintaining a smallpox hospital in South Clinton street in that place. Father McManus and others asked for the injunction two weeks ago. The authorities secured affidavits from many physicians, who expressed the opinion that the presence of the hospital was not dangerous to the neighborhood.

Health of the Army in the Philippines.—Surgeon-General Sternberg has received a report from Lieut.-Col. B. F. Pope, Chief Surgeon of the Division of the Philippines, in regard to the health of troops during the month ended December 15. It shows a decrease in the percentage of sickness, which Col. Pope says may be considered especially favorable in view of the long continuance of the rainy season and the active military operations in Samar and Batangas. The total number of deaths is seventy-seven, the same number as the previous month. Eleven soldiers died from wounds received in action and sixteen were drowned. There were 2,437 cases of sickness. The strength of the command being 39,040, the percentage of sickness to the command was 6.21. There was a decrease in the number of cases of typhoid and malarial fever, an increase of intestinal and gastric diseases. Bubonic plague has reappeared in the city of Manila and the Board of Health is conducting an active campaign against rats, with a view to preventing a spread of the plague. So far no such cases have appeared in the army.

The Needs of Bellevue and the Subsidiary Hospitals.—The New York County Visiting Committee for Bellevue Hospital and other public institutions declares in its annual report, just issued by its President, Dr. George G. Wheelock, that larger quarters are needed in the Harlem and Fordham Reception Hospitals and in the City Lodging House. Bellevue, the committee reports, needs repainting throughout, with new floors, new plumbing, a system of electric lighting and elevators, though an entirely new building would be better. The Harlem Hospital needs a new site and building. In the present hospital the bathing facilities are wholly inadequate. Fordham Hospital occupies leased property, and the buildings do not belong to the city. Building operations in the neighborhood have made it very uncomfortable for the patients, and there is no ward for children, of whom many are received as patients. Nor has the hospital any crematory, the used dressings being burned in a vacant lot. Another feature of the hospital's service which the committee criticises is the long distance over which patients are transported. Some of them have to be carried seven miles, and in emergency cases this has at times resulted in death. The committee therefore recommends the erection of a small emergency hospital in the eastern part of The Bronx. It is also recommended that female nurses be employed in preference to men, with orderlies to assist them in the heavy work of caring for the patients.

A Senseless Attack on Cats and Dogs.—The authorities of Plymouth, Pa., have declared war on all the dogs and cats of the town, and a number of official killers have been appointed whose trust it is to shoot every dog and cat found on the streets. The animals are being killed because it is believed they are responsible for the spread of smallpox, of which there are several cases in the township. Here is an opportunity for the antivivisectionists, or some other sects to make for once a sane protest in exposing the foolishness of these town authorities, who seem never to have heard of vaccination as a protection against smallpox.

Cancer Cultures.—It is stated in a London daily paper that Dr. Ross of the Indian Medical Service has succeeded in cultivating the germs of cancer, and has produced a malignant neoplasm by inoculating a guinea pig with the culture.

A Site for the Woman's Hospital has been purchased on 110th street, near Amsterdam avenue, the present hospital grounds in 49th street having been sold to the New York Central Railroad. It is proposed to erect a six-story building from plans selected in an architectural competition held some years ago.
